Dear Byas:

Enclosed are two copies of the Contamination Assessment Report (CAR) for the Trumbo Point Fuel Farm, Naval Air Station Key West, Florida. Two copies have been mailed to Jorge Caspary at FDEP, two copies to Jim Simmen at the facility, and one copy to Lt. Chad Jacoby at United States Coast Guard Group Key West for their review.

Should you have any questions, please contact me at your earliest convenience.

Sincerely,

ABB ENVIRONMENTAL SERVICES, INC.

FOREWORD

To meet its mission objectives, the U.S. Navy performs a variety of operations, some requiring the use, handling, storage, or disposal of hazardous materials. Through accidental spills and leaks and conventional methods of past disposal, hazardous materials may have entered the environment in ways unacceptable by today's standards. With growing knowledge of the long-term effects of hazardous materials on the environment, the Department of Defense initiated various programs to investigate and remediate conditions related to suspected past releases of hazardous materials at their facilities.

One of these programs is the Comprehensive Long-Term Environmental Action, Navy Underground Storage Tank (UST) program. This program complies with Subtitle I of the Resource Conservation and Recovery Act and the Hazardous and Solid Waste Amendments of 1984. In addition, the UST program complies with all appropriate State and local storage tank regulations as they pertain to each naval facility.

The UST program includes the following activities:

- registration and management of Navy and Marine Corps storage tank systems,
- contamination assessment planning,
- site field investigations,
- preparation of contamination assessment reports,
- remedial (corrective) action planning,
- implementation of the remedial action plans, and
- tank and pipeline closures.

The Southern Division, Naval Facilities Engineering Command (SOUTHNAVFACENGCOM) manages the UST program and the U.S. Environmental Protection Agency and the Florida Department of Environmental Protection (formerly Florida Department of

Environmental Regulation) oversee the Navy UST program at Naval Air Station (NAS) Key West.

Questions regarding this report should be addressed to the Commanding Officer, NAS Key West, Florida, or to SOUTHNAVFACENCOM, Byas Glover, Code 18410, at (803) 820-5651.

EXECUTIVE SUMMARY

The Trumbo Point Fuel Farm (TPFF) has been used as a fuel storage and distribution point by the Navy since 1942. The TPFF is the location of several aboveground storage tanks (ASTs), associated pipelines, and various pumphouses used to transport fuel to and from the ASTs. In addition to the various fuel pipelines, which are still active at the site, a large number of abandoned buried fuel pipelines are also present on the site. Fuels reported to have been stored and transported at the site include No. 6 fuel oil, Bunker C oil, diesel fuel, aviation gasoline (AVGAS), jet propellant (JP)-4 and JP-5 jet fuels, motor gasoline (MOGAS), waste oil, and hydraulic fluids. According to Navy personnel, the TPFF is currently used to store and dispense diesel fuel marine, JP-5 fuel, and MOGAS.

The land currently occupied by the U. S. Coast Guard (USCG) facility was previously owned and operated by Naval Air Station (NAS) Key West. The property was leased by the Navy to the Coast Guard in 1983. The facility primarily consists of two concrete piers (D-2 and D-3) and various buildings used to house operational and support services (maintenance shops, administration offices, living quarters, etc.). Pier D-1, located west of Trumbo Road and adjacent to the USCG property, is currently owned and operated by NAS Key West. Ships docking at Pier D-2 offload fuel for storage at the TPFF. Fuel dispensers on Piers D-2 and D-3 are used to support USCG operations.

ABB-Environmental Services, Inc. (ABB-ES), conducted a preliminary contamination assessment (PCA) in August 1993 to verify the findings of previous investigations and assess soil and groundwater contamination in areas not well documented during the previous investigations. The ABB-ES PCA was conducted from July through October 1993. At the request of the Navy, the area of investigation also included parts of the JSCG facility west of the TPFF site. During the PCA, 101 soil borings were drilled and 3 vertical extent monitoring wells were installed. Soil samples were collected from soil borings and analyzed for volatile organic compounds by organic vapor analyzer (OVA) analysis. Groundwater samples were collected from monitoring wells installed during previous investigations and from monitoring wells and specific soil borings completed during the PCA.

From January 1996 to April 1996, ABB-ES conducted a contamination assessment (CA) at the TPFF and USCG sites to collect data required to complete a contamination assessment report (CAR) for Florida Department of Environmental Protection approval and obtain site-specific data to evaluate potential remedial technologies. During the CA, 139 additional soil borings were conducted and 103 additional monitoring wells were installed. Soil samples were collected from soil borings and analyzed for volatile organic compounds by OVA analysis and, in some areas, for the Waste Oil Group parameters. Groundwater samples were collected from monitoring wells and analyzed for either the Kerosene Analytical Group or Waste Oil Group parameters. Sediment and surface water samples were collected and analyzed for the Kerosene Analytical Group parameters.

Based on the findings of the CA field investigations and laboratory analytical results, a summary of existing conditions at the site are presented on Figure 1 and provided below:

FINDINGS

- The sediments encountered during drilling operations are generally composed of silty clay, oolitic lime mud, and oolitic limestone. Groundwater beneath the site was encountered at depths of approximately 4 to 6 feet below land surface (bls) and is classified as G-III. The direction of groundwater flow in the surficial zone has consistently been radially away from the TPF and toward the northwest on the piers.
- Five areas of excessively contaminated soil were identified by OVA headspace analyses. The largest areal extent of soil contamination is located immediately north of the JP-5 tanks in the area of the former AVGAS ASTs. Other areas of excessively contaminated soil included Pier D-2 in the vicinity of Building 105, the area around the basketball court and softball field, the west end of Pier D-1, and the east end of Pier D-1.
- Four areas of excessively contaminated soil were identified by laboratory analysis. Total recoverable petroleum hydrocarbon (TRPH) concentrations in soil exceed the Chapter 62-770, Florida Administrative Code (FAC) target level of 50 parts per million (ppm) in the former tank D-5 area, the area around tank D-21, the area of the oil-water separator, and the area of the oily-wastewater pump station on Pier D-1.
- The sediment sample analytical data collected from the surface water bodies adjacent to the site indicate no detections above the detection limit for volatile organic compounds and ethylene dibromide; however, elevated concentrations of polynuclear aromatic hydrocarbons, TRPH, and lead were detected in some or all of the samples. The source of contamination in the surface water sediment may be attributed to past oil seepage, bilge water discharges, and particles of lead-based paint from naval vessels operating at the facility.
- Two areas of total volatile organic aromatics (VOA) contamination in groundwater were identified during the CA. One large area is in the northeast part of the fuel farm in the vicinity of the JP-5 tanks. The highest total VOA concentrations in this area were observed in monitoring well MW-4 [1,193 parts per billion (ppb)] and MW-60 (670 ppb), which exceeded the 50 ppb State target level. The second smaller area is on the north side of Pier D-1 in the vicinity of the oily wastewater pipelines. Total VOA concentrations observed in MW-15 (87.2 ppb) exceeded the 50 ppb State target level.
- The benzene contamination plume overlaps the area of total VOA contamination and is generally in the same location. The area of benzene contamination includes the former AVGAS AST area occupied by tanks D-15 through D-18 and the associated pipelines. The highest

benzene concentrations were in the groundwater samples collected from MW-4 (990 ppb) and MW-60 (620 ppb). This area of benzene contamination greatly exceeded the Chapter 62-770, FAC, target level of 1 ppb.

- Total naphthalenes concentrations exceeded the Chapter 62-770, FAC, Class G-II groundwater target level of 100 ppb in the samples collected from monitoring wells MW-15 (174 ppb), MW-50 (196 ppb), and MW-55 (1,750 ppb). MW-15 is located on the north side of Pier D-1, MW-50 is located north of Building D-19 and MW-55 is located north of the JP-5 tank #1.
- Groundwater petroleum contamination appears to extend to below 30 feet bls in the northeast area of the TPF. Laboratory results reported contaminant concentrations in the groundwater sample collected from vertical extent well MW-74D (30 feet bls) are 38 ppb benzene, 53.7 ppb total VOA, and 19.2 ppb total naphthalenes. MW-74D was resampled in July 1996 and analyzed for U.S. Environmental Protection Agency Method 602 only. Reported concentrations are 57 ppb benzene and 66.6 ppb total VOA.
- Three areas of TRPH contamination in groundwater exceeding the Chapter 62-770, FAC, target level of 5 ppm were identified. These areas are associated with samples collected from monitoring wells MW-55 (157 ppm), KWM-01 (15.7 ppm) and MW-86 (5.1 ppm).
- Lead concentrations in all monitoring well samples did not exceed the Chapter 62-770, FAC, target level of 50 ppb for Class G-II groundwater.
- Chlorinated compounds were detected in low concentrations in monitoring wells in isolated areas of the site.
- Free-floating petroleum product was observed in 18 site monitoring wells during the CA.
- No compounds were detected in any of the surface water samples collected except for toluene (1 ppb) in sample W003 and methylene chloride (3.9 ppb) in sample W011. It is likely these compounds are attributed to activities associated with boats and ships docked at the site.
- No potable water sources were identified within a 0.25-mile radius of the site. Water is supplied via aqueduct from the mainland.

CONCLUSIONS. The following conclusions are based on the findings of the CA and site conditions.

- Excessive soil contamination in the area of the former AVGAS ASTs and associated pipelines is apparently related to leaks or releases from the former ASTs and the fuel lines in the northern area of the TPF. Overall, soil contamination is limited to an interval 1 to 2 feet above the water table.

- The areal extent of groundwater contamination exceeding Chapter 62-770, FAC, target levels is associated with the areas of excessively contaminated soil.
- Groundwater contamination extends below 30 feet of the surficial aquifer in the northeast area of the TFFF.
- The source of groundwater contamination is apparently due to previous releases from the AVGAS fuel pipelines in the vicinity of the ASTs, releases from pipeline junctions, a release from the oily wastewater pipeline, and a release from the oily wastewater pump station.
- The sources of chlorinated compounds detected in site groundwater samples are suspected to be solvents and degreasing agents used at the site, and compounds used by the analytical laboratory during sample preparation. Chlorinated compounds do not appear to be a significant concern at the site.
- There are no potable water wells within a 0.25-mile radius of the site and drinking water is obtained via aqueduct from the mainland. The risk to human health caused by groundwater contamination is extremely low.
- There is no evidence to indicate that groundwater contaminants are migrating off the facility. Contamination is moving toward Fleming Key Cut, but does not appear to be a threat to surface water because of the sea wall. For this reason, groundwater contamination at the site appears to be a low risk to area fish and wildlife.

RECOMMENDATIONS. Based on the findings, conclusions, and interpretations of the CA, ABB-ES recommends the continued implementation of an interim remedial action and the development of a remedial action plan (RAP). The primary contamination includes excessively contaminated soil, benzene, total VOAs, naphthalenes, and TRPH in groundwater. Free-product recovery efforts initiated at the site should be continued. An RAP will be developed to address the requirements of Chapter 62-770, FAC. One deep monitoring well, screened from 45 to 50 feet bls, should be installed adjacent to MW-74D during the RAP to delineate the vertical extent of groundwater contamination.

ACKNOWLEDGMENTS

In preparing this report, the Underground Storage Tank Section of the Comprehensive Long-Term Environmental Action, Navy Group at ABB Environmental Services, Inc., commends the support, assistance, and cooperation provided by the personnel at Naval Air Station Key West, Key West, Florida, United States Coast Guard Group Key West, and Southern Division, Naval Facilities Engineering Command.

1.0 INTRODUCTION

ABB Environmental Services, Inc. (ABB-ES), was contracted by Southern Division, Naval Facilities Engineering Command (SOUTHNAVFACENGCOM) to conduct a contamination assessment (CA) and develop a Contamination Assessment Report (CAR) for the Trumbo Point Fuel Farm (TPFF) and the U.S. Coast Guard (USCG) facility at Trumbo Point Annex, Naval Air Station (NAS) Key West, in Key West, Florida. The scope of services for the work is described in Contract Task Order (CTO) No. 95, the Plan of Action, and the Preliminary Contamination Assessment Plan for CTO No. 95.

1.1 PURPOSE. The purpose of the CA was to assess the extent of petroleum contamination in soil and groundwater at the TPFF and USCG facility, and, if needed, recommend appropriate remedial action at the site in accordance with Chapter 62-770, Florida Administrative Code (FAC), guidelines.

1.2 SCOPE. The scope of services developed to perform the CA included

- collecting soil samples in the unsaturated (vadose) zone for headspace analysis using an organic vapor analyzer (OVA) to assess the horizontal and vertical extent of petroleum-contaminated soil;
- installing and sampling groundwater monitoring wells to assess the horizontal and vertical extent of groundwater contamination;
- collecting soil samples for waste-oil compound analyses and remedial alternative evaluation;
- collecting surface water and surface-water sediment samples;
- onsite gas chromatograph (GC) screening of groundwater and soil samples;
- laboratory analysis of soil, groundwater, surface water, and surface water sediment samples;
- collecting water-level data to assess the groundwater flow direction and hydraulic gradient at the site;
- conducting monitoring well and water table elevation surveys;
- a tidal influence study;
- pumping tests;
- vadose-zone air permeability tests;
- a potable well inventory within a 0.25-mile radius of the site; and,
- reducing and analyzing pertinent data gathered during the CA to complete this CAR.

The CA field investigation was conducted from January 1996 through April 1996 and July 1996. The following sections of this CAR present the background information, data compilation, field investigation results, and recommendations for further action at the site.

2.0 SITE DESCRIPTION AND HISTORY

NAS Key West, Monroe County, Florida, is located approximately 150 miles southwest of Miami. The TPF and USCG sites are located along the northern shore of Key West, south of Fleming Key Cut (Figure 2-1). The TPF and the USCG facilities are bordered on the north by Fleming Key Cut, on the west by Man of War Harbor, on the east by Mustin Street, and on the south by Whiting Avenue (Figure 2-2). Piers D-1, D-2, and D-3, located at the USCG facility, serve as a fuel depot for ships.

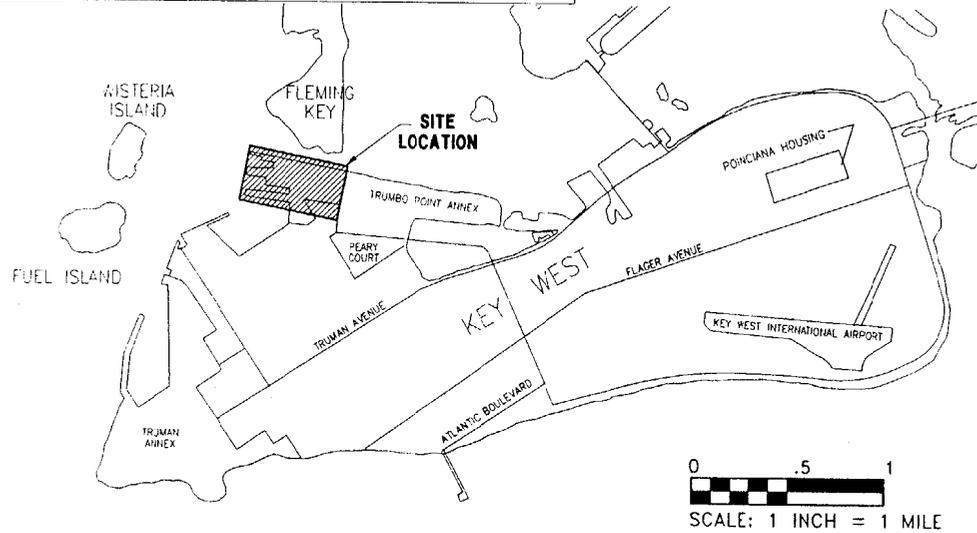

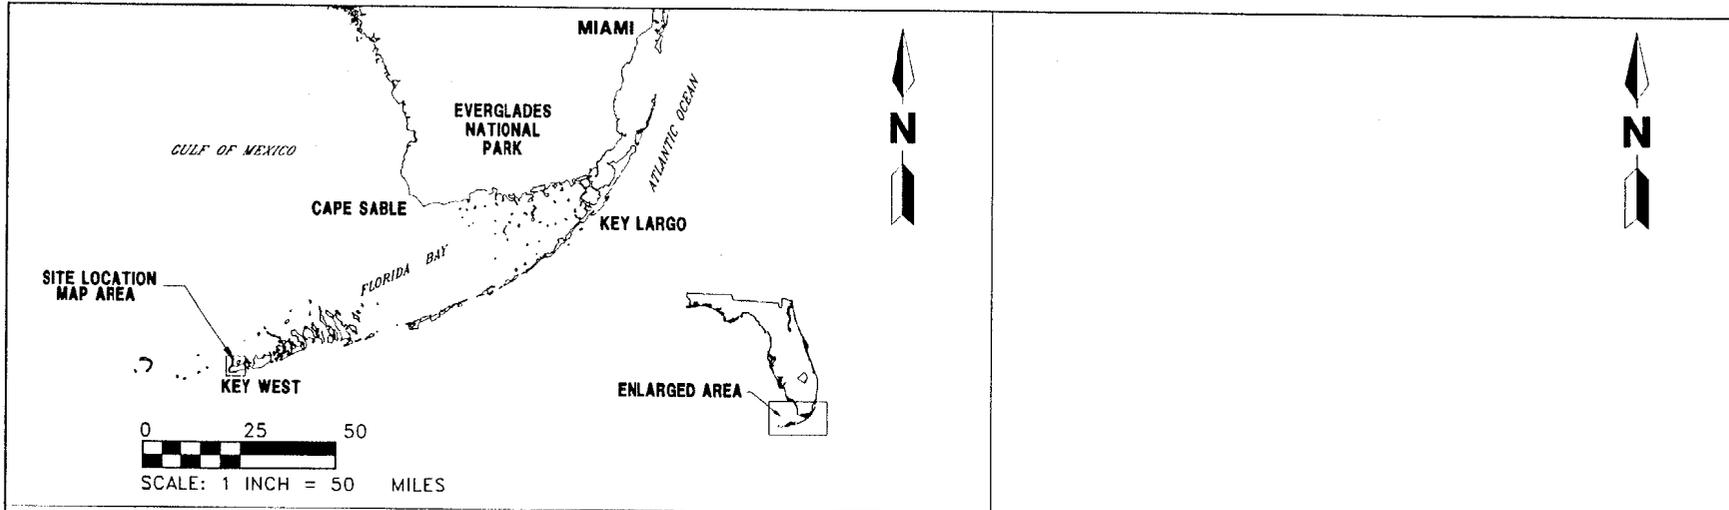

The TPF has been used as a fuel storage and distribution point since 1942 (Envirodyne Engineers, Inc., 1985). Fuels reported to have been stored and transported at the site include No. 6 fuel oil, Bunker C oil, diesel fuel, aviation gasoline (AVGAS), jet propellant (JP)-4 jet fuel and JP-5 jet fuel, motor gasoline (MOGAS), waste oil, and hydraulic fluids (Geraghty & Miller, 1987). According to Navy personnel, the TPF is currently used to store and dispense diesel fuel marine (DFM), JP-5 fuel, and MOGAS.

The TPF is the location of several aboveground storage tanks (ASTs), associated piping, and various pumphouses used to transport fuel from the ASTs (Figure 2-2). The site entrance is located along Trumbo Road near Building D-19. Building D-19 is used as an office and storage facility by site personnel. Buildings D-3A, D-22 through D-26 are pumphouses, which are now used or were formerly used to transport fuel from the site. The TPF is surrounded by an 8-foot high chain-link fence. A concrete seawall extends along the northern perimeter of the site. The seawall is approximately 1-foot thick and extends to a depth of approximately 15 to 20 feet below land surface (bls).

The land currently occupied by the USCG facility was previously owned and operated by NAS Key West. The property was leased by the Navy to the Coast Guard in 1983. The facility primarily consists of two concrete piers (D-2 and D-3) and various buildings used to house operational and support services (maintenance shops, administration offices, living quarters, etc.). Pier D-1, located west of Trumbo Road and adjacent to the USCG property, is currently owned and operated by NAS Key West. Ships docking at Pier D-2 offload fuel for storage at the TPF. Fuel dispensers on Piers D-2 and D-3 are used to support U. S. Coast Guard operations.

In addition to the various fuel pipelines, which are still active at the site, a large number of active buried utilities (electric, communications, water, and sewer), abandoned utilities and abandoned buried fuel pipelines are present on the site (see Figure 2-3).

2.1 ABOVEGROUND STORAGE TANKS. There are eight active and five inactive ASTs at the TPF. AST volumes and construction details are presented in Table 2-1. Three steel JP-5 jet fuel tanks (tanks 1 through 3) are located in the north central and northeastern sections of the site. Tanks 1, 2, and 3 are operated by Key West Pipeline Company. Tanks D-1 through D-3, D-4, and D-6 are concrete earth mounded tanks. Tanks D-1 through D-3, located along the western margin of the TPF, are maintained by Avantra, Inc., and are used to store DFM. Tank D-2 has recently been emptied and is no longer in use. A 20,000-gallon MOGAS AST is

D-1292	MOGAS	20,000	Active AST	December 1991	--
D-1293	MOGAS	15,000	Removed AST	Unknown	December 1991

¹ Contained JP-4 jet fuel prior to 1975.

² Converted to DFM storage by 1985.

³ Used for waste oil overflow from tank D-21 from 1982 to 1985.

Notes: JP-5 = jet propellant 5 jet fuel.
AST = aboveground storage.
-- = not removed.
DFM = diesel fuel marine.
AVGAS = aviation gasoline.
UST = underground storage tank.
MOGAS = motor gasoline.
JP-4 = jet propellant 4 jet fuel.

located west of DFM tank D-2 at the western edge of the TFFF. A 1,000-gallon diesel AST is located on the east side of Building D-29 at the eastern edge of the TFFF.

Several ASTs, which formerly contained fuel, have been removed from the site. Eleven AVGAS tanks, installed in 1942, were abandoned in the late 1940s (Envirodyne Engineers, Inc., 1985). These AVGAS tanks (D-8 through D-18) were formerly located in the area now occupied by the JP-5 tanks. Concrete sump tanks associated with tanks D-15 through D-18 were removed in 1995. DFM ASTs D-5 and D-7, located in the southeast part of the site, were removed in 1985. Two 15,000-gallon MOGAS ASTs located north of Building D-19 were removed in 1992 and replaced with the 20,000-gallon MOGAS AST currently in use. Two inactive DFM ASTs, tanks D-4 and D-6, located in the central and southern sections of the TFFF, respectively, are scheduled for removal in November 1996.

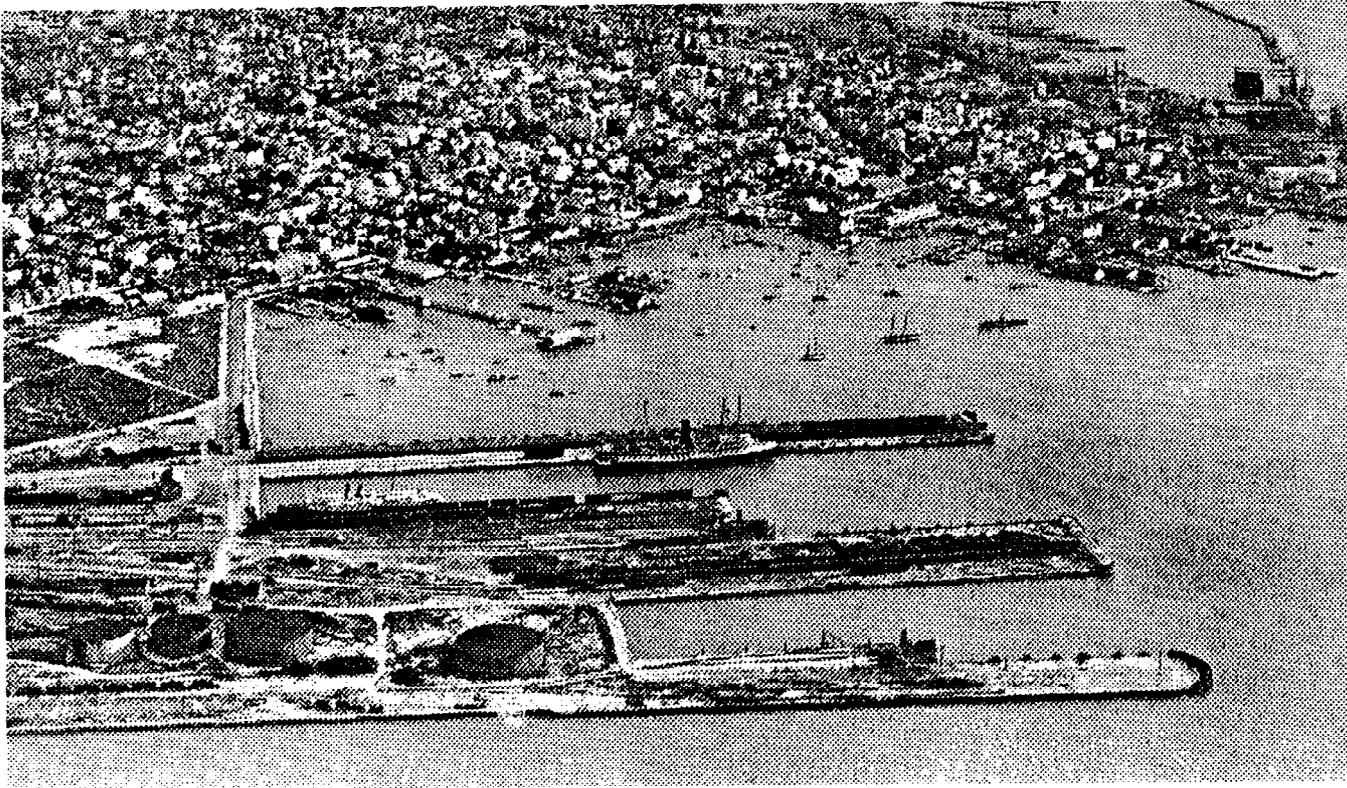

A 1,050-gallon AST, tank D-21, is located on the west side of the site (Figure 2-2). The AST was installed in 1942 and was used as a ballast sludge tank (Envirodyne Engineers, Inc., 1985). By the 1970s, the AST was used for the storage of waste oil and hydraulic fluid. Until the late 1970s, the waste oil was sold to contractors who hauled the material from the TFFF. Subsequently, the waste oil was allowed to accumulate and by 1982 the AST was full. Approximately 200 to 300 gallons of waste oil were transferred each month to tank D-5 between 1982 and 1985. Tank D-5 (discussed above) was removed from the site around 1985.

Historical aerial photographs indicate there were four large ASTs at the site in 1930 (La Gorce, 1930). Two of the four ASTs were located at the USCG facility (Figure 2-2): one near the present location of the basketball court and the second at the present location of the softball field near Trumbo Road. The third and fourth AST were located between DFM tanks D-1 and D-2. The contents of the three ASTs are unknown. Aerial photographs suggest that they may have been used for fuel storage to supply ships docked at Piers D-1, D-2, and D-3 (see Photograph 2-1). The ASTs were reportedly removed during the early 1960s.

Several ASTs are currently in use at the USCG Station. Two 12,000-gallon diesel fuel ASTs are located east of USCG Building 101, which is located on the east side of the facility. One 36,000-gallon bilge-water AST is located near the entrance gate. A 1000-gallon diesel AST is located at the southeast corner of Building 105, a 250-gallon diesel AST is located north of Building 105, and a 500-gallon gasoline AST is located at the small boat dock on the southeast corner of Pier D-2 (see Figure 2-2).

2.2 UNDERGROUND STORAGE TANKS. A 550-gallon underground storage tank (UST) is located on the east side of Building D-26. It reportedly contained gasoline to run the equipment in Building D-26 and is currently inactive. A similar UST was located on the east side of Building D-30 in the area between former tanks D-5 and D-7. Building D-30 was removed along with Tanks D-5 and D-7 in 1985.

A UST was also formerly located west of Building D-23 and reported to store solvents, waste oil, pesticides, and polychlorinated biphenyls. The size of the UST and date of removal are not known.

Two 10,000-gallon USTs used primarily for AVGAS storage are located east of USCG Building 108. These USTs were degassed and abandoned in place in 1995. A diesel fuel UST is located in a small fenced-in area west of Building B-43. This UST is scheduled for removal later in 1996. A diesel UST, located west of Building 102, is the only known active UST on the USCG property.

2.3 FUEL PIPELINES. Several aboveground and underground fuel pipelines are located at the site (see Figures 2-2 and 2-3). DFM and JP-5 pipelines are used to transport fuel to the fuel farm from Pier D-2 at the USCG facility. Aboveground JP-5 pipelines extend north from JP-5 tanks 1 through 3 and connect with an underground JP-5 pipeline, which continues west into the USCG facility along the south side of the softball field to fueling station 4 on Pier D-2. Within the USCG facility, the JP-5 pipeline is aboveground along the north side of Pier D-2. An underground DFM pipeline connects DFM tanks D-1, D-2, and D-3 and extends west to Trumbo Road from DFM tank D-3. The DFM pipeline then continues north along the east side of Trumbo Road to the MOGAS AST. From that point the pipeline extends west to the fueling station on Pier D-2, parallel to the JP-5 pipeline (see Figure 2-3).

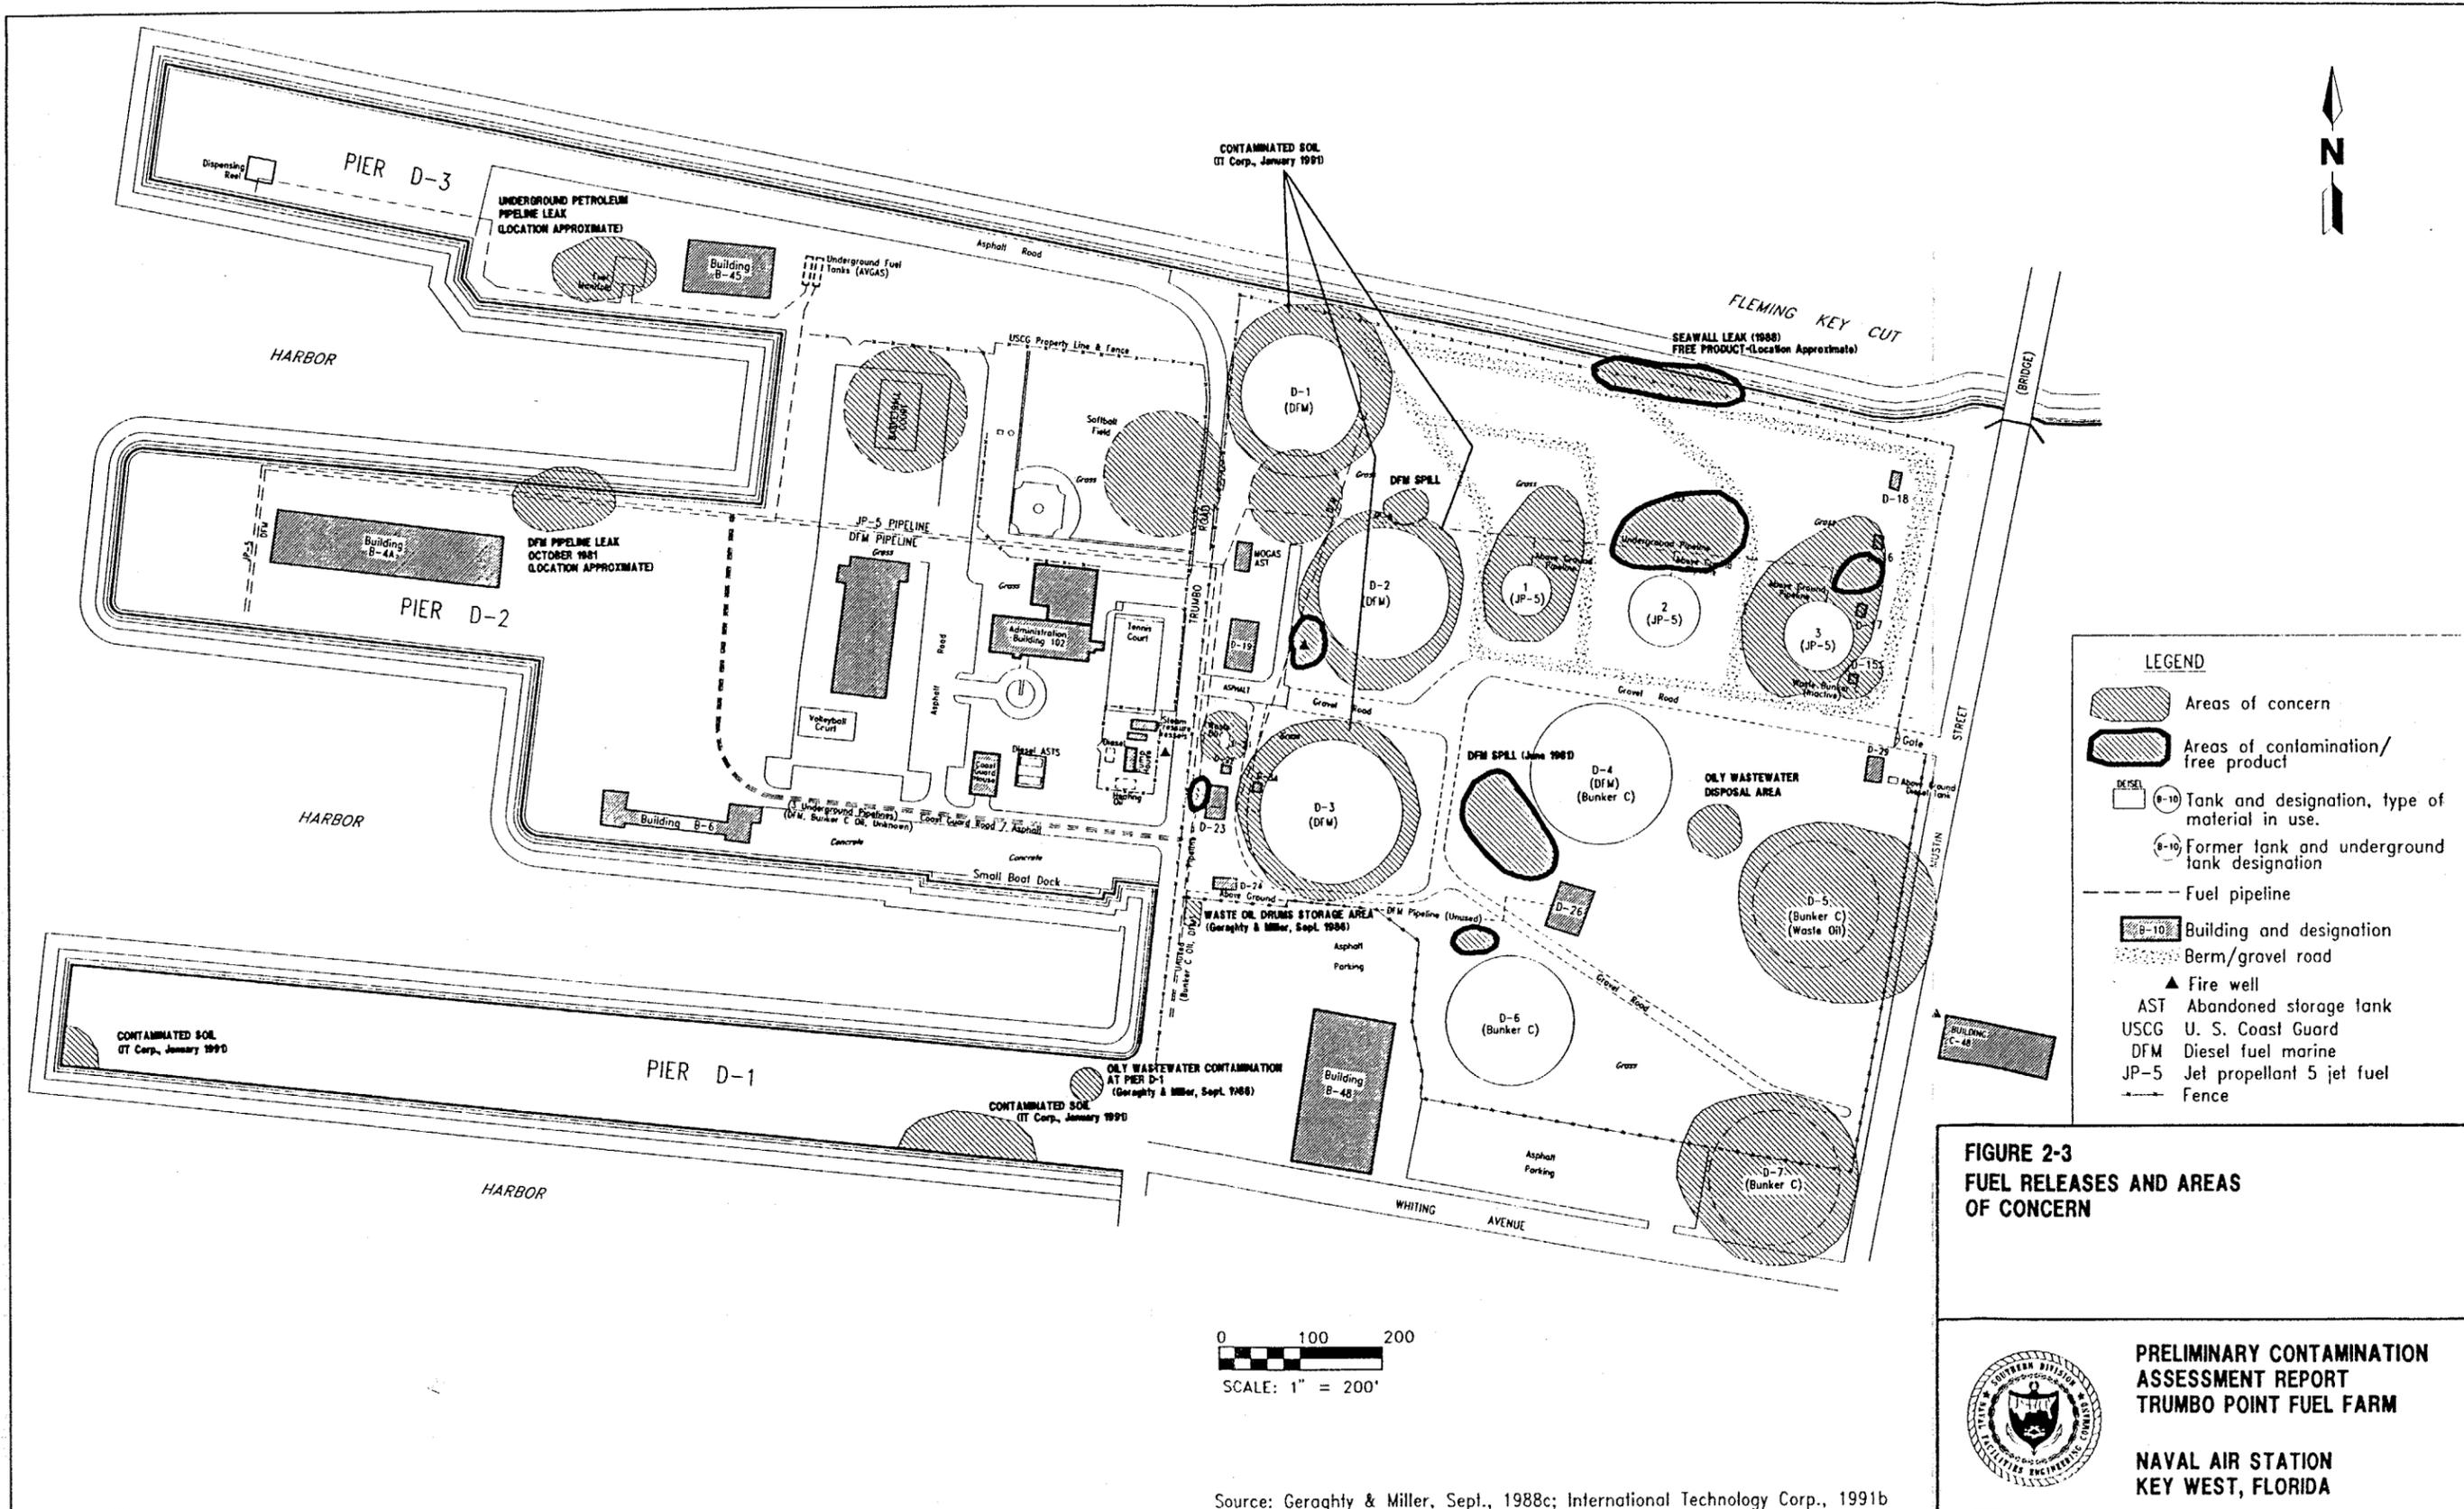

Several unused fuel pipelines are present at the TPFf site. An abandoned DFM pipeline extends from pumphouse D-26 near DFM tank D-4 to another abandoned DFM pipeline located along the west fenceline of the site. An abandoned underground Bunker C oil pipeline reportedly existed along the western fenceline of the TPFf parallel to the abandoned DFM pipeline (see Figure 2-3).

According to USCG facility personnel, three abandoned underground pipelines are located under the USCG facility access road south of the tennis court. One pipeline was used to transport DFM and a second transported Bunker C oil. The third line is described as a 4-inch sump. The pipelines continue west along the access road, then turn north near Building 103 toward the slip north of Pier D-2.

An oily-wastewater pipeline and a pump station are located on Pier D-1. According to facility personnel, the oily-wastewater pipeline continues from the pump station to an oil-water separator located northwest of Building B-48 (see Figure 2-2). The pump station and oil-water separator are no longer in use. An oily-wastewater pipeline and pump station located on the north side of Pier D-3 have never been used according to USCG personnel.

2.4 PREVIOUS FUEL RELEASES AND CAS. An initial assessment study indicated that two fuel releases occurred at the facility in 1981 (Envirodyne Engineers, Inc., 1985). In June 1981, there was a reported release of 5,000 to 6,000 gallons of DFM from a corroded pipeline located between tank D-4 and the D-26 pump house. All DFM was reportedly contained with no discharge to surface waters (Envirodyne Engineers, Inc., 1985). In October 1981, a pipeline leak on Pier D-2 at the USCG facility resulted in the discharge of 300 gallons of DFM into harbor waters. The spill was contained by boom and recovered (Envirodyne Engineers, Inc., 1985).

CA investigations have been conducted at the TPFf since 1985, and several areas of concern were identified during these investigations. Geraghty & Miller (June 1985) conducted a subsurface hydrocarbon investigation, during which, 10 monitoring wells were installed at the TPFf. The Geraghty & Miller investigation confirmed the DFM contamination in the vicinity of tank D-4 reported by Envirodyne Engineers, Inc. (March 1985).

Source: Geraghty & Miller, Sept., 1988c; International Technology Corp., 1991b

0076 G 027

During a subsequent verification study (Geraghty & Miller, 1987), 15 soil borings were drilled and 6 additional monitoring wells were installed at the TPDF. Free product was detected in monitoring wells in the vicinity of JP-5 tanks 2 and 3, DFM tank D-4, and in the vicinity of Building D-23 located west of DFM tank D-3 and south of former waste-oil tank D-21. Dissolved petroleum constituents were detected in the vicinity of JP-5 tank 3. Additional site investigation and remedial action was recommended (Geraghty & Miller, 1987).

Another area of concern was identified along the northern boundary of the TPDF (Geraghty & Miller, 1988c). Geraghty & Miller personnel observed fuel seeping through openings in the seawall north of JP-5 tank 2 along the northern site boundary. The openings were sealed and a pit was excavated on the landward side of the seawall to recover free product. Several weeks later, fuel was again observed seeping through the seawall. The seawall was again sealed and another pit was excavated to recover the free product.

During an expanded site investigation (Geraghty & Miller, 1988b), free product detected in the vicinity of Building D-23, JP-5 tank 2, and DFM tank D-4 was confirmed. Free product was also detected in a monitoring well (KWM-24) northwest of tank D-6. In addition, the September 1988 Geraghty & Miller investigation identified the following potentially contaminated areas at the site:

- the area north of DFM tank D-2 in the northwest section of the site, reportedly caused by overfilling tank D-2;
- the area between tank D-4 and former tank D-5 in the east-central section of the site, where oily wastewater was reportedly disposed of;
- a waste-oil drum storage area near an oil-water separator located south of Building D-24 on the western perimeter of the site;
- a former waste-oil UST near Building D-23 located on the western perimeter of the site, where site personnel reported that the UST may have been used to store solvents, waste oil, pesticides, and polychlorinated biphenyls;
- in two separate areas on Pier D-1 at the USCG facility suspected to result from releases of oily wastewater; and
- in the south central area of Pier D-3 at the USCG facility, where a release resulting from an underground petroleum pipeline is the reported source of contamination.

Geraghty & Miller (1988a) recommended further investigation at the TPDF and Piers D-1 and D-3 and presented a workplan for an expanded site investigation and remedial field investigation.

A supplemental site investigation was conducted in 1990 by International Technology Corporation (ITC). Forty-four soil borings and four monitoring wells were completed and sampled. Excessive soil contamination as defined in Chapter 62-770, FAC, was detected in the vicinity of DFM tanks D-1 through D-3, and JP-5 tanks 1 and 2, and along the southern boundary of Pier D-1 at two separate locations. ITC (1991b) recommended that remedial action be implemented at the

site. The recommended remedial action included treating excessively contaminated soil and sampling groundwater from existing monitoring wells.

A remedial pilot study was designed to test and evaluate a method for treating contaminated groundwater and recovering free product in the subsurface east of tank D-4 (Geraghty & Miller, 1988a). The pilot study was implemented by ITC in 1990 and 1991. The remedial system consisted of an infiltration gallery with a center sump equipped with groundwater and free product pumps. Recovered free product was pumped into a 5,000-gallon product tank. Contaminated groundwater was treated by an air-sparger system designed to treat groundwater at the rate of 50 gallons per minute (gpm). A leach bed was used for the disposal of treated groundwater.

The remedial system operated for 180 days. Because of the low horizontal permeability of soil, the actual groundwater yield was 1 gpm. Approximately 1,000 gallons of free product were recovered and 155,000 gallons of groundwater were treated. ITC (1991a) concluded that the recovery system used at the TPFf site was not a feasible remedial alternative because the low hydraulic conductivity of the soil limits the formation of a capture zone and inhibits groundwater recovery and the transport of free product. ITC (1991a) recommended extensive trenching to remove contaminated soil and to improve access to free product, and a site bioassessment and biotreatability study to evaluate the feasibility of bioremediation.

ABB-ES was contracted by SOUTHNAVFACENCOM to conduct a CA and develop a CAR for the TPFf and USCG facilities. During the initial site inspection in November 1992, ABB-ES observed free product in the fire well located between Building D-19 and tank D-2 in the western part of the TPFf. Evidence of soil and groundwater contamination was also observed in the following locations: the area surrounding JP-5 tank 1, located in the north central part of the TPFf; the area surrounding JP-5 tank 3, located in the northeast section of the TPFf; the area surrounding the inactive waste Bunker C tank (sump tank for D-15) and the sump tanks for D-16 through D-18, located near JP-5 tank 3 in the northeastern section of the TPFf; the area surrounding former tank D-5, located in the eastern section of the TPFf; and the area surrounding former tank D-7, located in the southern part of the TPFf.

ABB-ES conducted a preliminary contamination assessment (PCA) in August 1993 to verify the findings of previous investigations and assess soil and groundwater contamination in areas not well documented during the previous investigations. The ABB-ES PCA was conducted from July through October 1993. At the request of the Navy, the area of investigation also included parts of the USCG facility west of the TPFf site. The preliminary CAR (PCAR) was submitted to SOUTHNAVFACENCOM in April 1994.

During the PCA, 101 soil borings were drilled and 3 vertical extent monitoring wells were installed. Soil samples were collected from soil borings and analyzed for volatile organic compounds (VOCs) by OVA analysis. Groundwater samples were collected from monitoring wells installed during previous investigations and from monitoring wells and specific soil borings completed during the PCA. Groundwater samples collected from soil borings were analyzed for total recoverable petroleum hydrocarbons (TRPH). Groundwater samples collected from monitoring wells were analyzed for constituents of the Kerosene analytical group as defined in Chapter

62-770, FAC. The findings, conclusions, and recommendations of the 1993 PCA are reported in the 1994 PCAR, which is presented in Appendix A.

In early 1995, an unknown quantity of DFM was released on the west side of the Trumbo Point Fuel Farm. The release occurred near the junction of the 12-inch DFM line and a smaller line that extends west to the USCG. An unknown quantity of soil was excavated in the area of the release and three 8-inch recovery wells were installed to a depth of approximately 9 feet bls. An unknown quantity of free product and groundwater were recovered from these wells.

In January 1996, Bechtel Environmental, Inc. (Bechtel), initiated the construction of two gravel-filled trench systems with sumps for the recovery of free product observed in the vicinity of tanks D-2 and D-4 during the PCA. The location of these trenches and the distribution of free product are discussed in Section 5.5.

From January 1996 to April 1996, ABB-ES conducted a CA at the TPF and USCG sites to collect data required to complete a CAR for Florida Department of Environmental Protection (FDEP) approval and obtain site-specific data to evaluate potential remedial technologies. Analytical laboratory results, findings, conclusions, and recommendations based on the CA data are incorporated in this CAR.

3.0 SITE CONDITIONS

3.1 SITE TOPOGRAPHY AND SURFACE FEATURES. The land surface at both the TPF and the USCG station is relatively flat, except where 8-foot high, gravel berms separate the JP-5 ASTs in the northern part of the TPF. Earthen mounds surround tanks D-1 through D-4, and D-6; and several gravel roads in the south section of the TPF are graded above the surrounding land surface. Except for the berms and mounds, ground elevation at the site varies from approximately 5 to 7 feet above mean sea level (msl).

Most of the TPF site is covered by grass, except paved areas in the vicinity of Building D-19 and the gravel roads and berms. The USCG station, however, is predominantly covered with asphalt and concrete except for the northeast corner of the site where the softball field and gazebo are located. Parking lots outside the southern edge of the TPF near Building B-48 are covered with asphalt. Building B-48 activities are not related to activities at the TPF.

There are three fire wells at or near the site. One fire well is located on the southwest side of DFM tank D-2, another is located near the northwest corner of Building C-48 on the east side of Mustin Street, and the third is located on the west side of Trumbo Road near Building B-43 (the pumphouse) at the USCG facility.

3.2 SITE GEOLOGY. The site is located in the lower Florida Keys which are overlain by a mantle of oolite limestone of the Miami Limestone. The oolite limestone is thickest in the northern part of Stock Island, thinning to the south and southwest. Beneath the Miami Limestone lies the Key Largo Limestone, which is almost entirely composed of ancient coral reef fossils. Hoffmeister (1974) reported the Miami Limestone to be 27 feet thick and the Key Largo Limestone greater than 270 feet thick in the western part of Key West. The natural grade in much of the area in and around Boca Chica Key and Key West has either been altered or is completely manmade consisting of imported fill material. Therefore, it is not uncommon to encounter fill materials at or near the surface.

3.3 REGIONAL HYDROGEOLOGY. The highly transmissive limestone of the lower keys generally contain brackish or saline water. Small areas of fresh groundwater exist on some of the larger islands (Black, Crow, and Eidness, 1977). The water-table aquifer is contained within both the Miami and Key Largo Limestones. Freshwater lenses that do exist are Class G-III groundwater with total dissolved solids exceeding 10,000 parts per million (ppm) and are subject to saltwater intrusion through the porous Key Largo Limestone and upward to the less porous Miami Limestone (Black, Crow, Eidness, 1977; McKenzie, 1990).

Groundwater in the Key West area discharges directly to the marine surface waters surrounding the islands. Many of these marine waters have been designated as Outstanding Florida Waters, a classification that affords them the highest environmental protection standards.

Due to the low land surface elevations in the lower keys, the water table is shallow. Recharge to the water table aquifer is directly from precipitation, and infiltration is rapid. Discharge, via groundwater flow, is to the surrounding surface waters. Water table elevations can be greatly influenced by local

rainfall and tides. The volume of fresh groundwater in the Key West area is limited; therefore, freshwater wells of any consequence do not exist. Potable water supplies are obtained by rainwater catchment, reverse osmosis desalination, or imported from the mainland by way of the Florida Keys aqueduct.

3.4 SITE-SPECIFIC HYDROGEOLOGY. Site-specific hydrogeologic characteristics were based on information obtained during soil boring and monitoring well installation and from previous investigations.

Subsurface material from land surface to a depth of approximately 3 feet bls is composed of hard, sandy limestone fill mixed with gravel and shell fragments (ITC, 1991a). Material from 3 feet bls to approximately 13 feet bls is generally a soft, silty to sandy limestone mud. A sandy to gravelly limestone occurs from 13 feet bls to 50 feet bls (the maximum depth of site monitoring wells). Site lithologies are graphically presented in soil boring logs for monitoring wells MW-1D through MW-107. Soil boring logs are attached in Appendix B, Lithologic Logs.

Grain size, permeability, pH, moisture, cation exchange capacity (CEC), and total organic carbon (TOC) analyses were performed on one composite soil sample collected from 0 to 4 feet bls near Trumbo Road, northwest of DFM tank D-3 (ITC, 1991b). Grain size analysis was representative of poorly sorted sand and gravel with an average particle diameter of 3 millimeters. Particles ranged in size from cobble to clay. The permeability was 1.8×10^{-6} centimeters per second, with a uniformity coefficient of 1,025. TOC content was 4,900 milligrams per kilogram, moisture content was 39.2 percent, pH was 8.35, and CEC was 49.22 milliequivalents per gram.

The water table was encountered at depths ranging from 4 to 7 feet bls during this investigation. A tidal study performed during August 1990 indicates that water elevations are tidally influenced (ITC, 1991b). Sea level fluctuations ranged from 0.9 feet below msl to 1.4 feet above msl, and groundwater elevations ranged from 0.4 to 3.0 feet above msl. Groundwater elevation measurements in three wells indicated a northwest flow direction at the TPDF (ITC, 1991b). Measurements recorded during the ABB-ES 1993 PCA indicated groundwater flow direction across the site was radially away from the center.

Recent groundwater, tidal, and hydrogeologic data collected during the CA are presented in Sections 5-6 through 5-11 in this report.

4.0 METHODOLOGIES AND EQUIPMENT

Methodologies and equipment used during the field investigation were in conformance with the ABB-ES, FDEP-approved, Comprehensive Quality Assurance Program Plan.

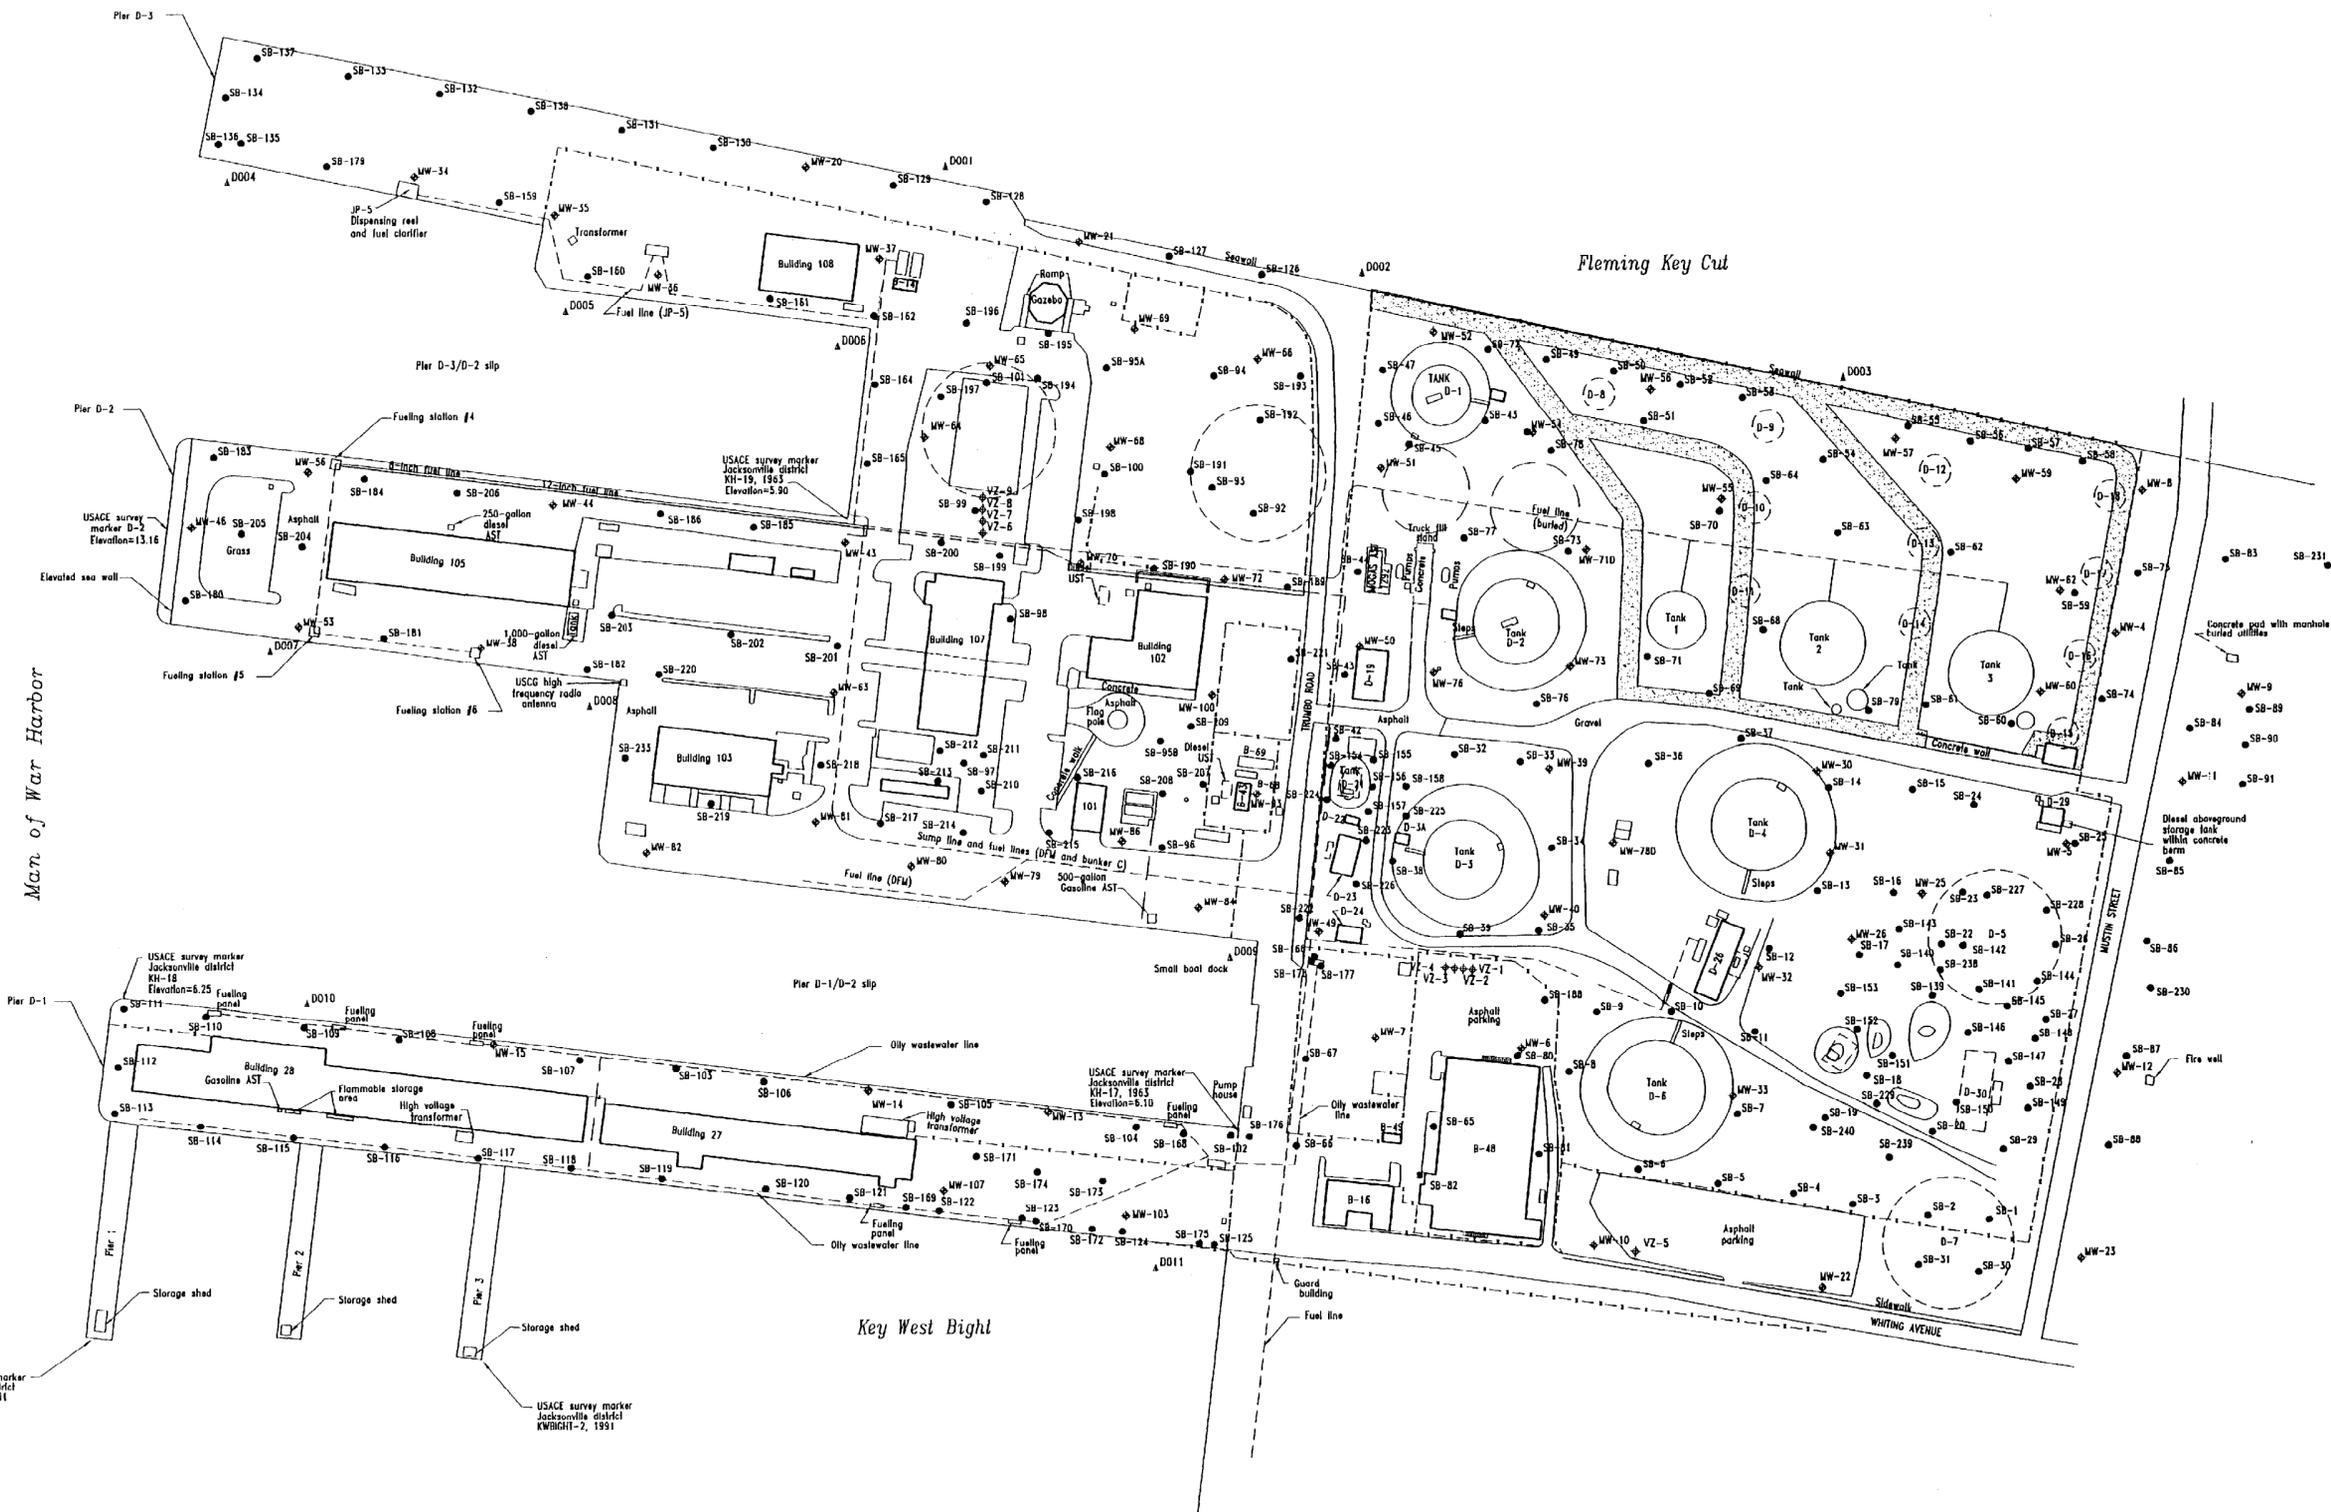

4.1 SOIL BORING PROGRAM. During the CA, 34 soil borings at the TPF and 105 soil borings at the USCG facility (SB-102 through SB240) were advanced into the water table to assess the horizontal and vertical extent of petroleum contamination in the unsaturated zone, to characterize the type of subsurface material, and to aid in the placement of groundwater monitoring wells. Soil borings SB-1 through SB-101 were performed during the PCA in August 1993. Soil boring locations are presented on Figure 4-1.

The soil borings were advanced using a truck-mounted drill rig equipped with 4.25-inch hollow-stem augers. Soil samples were collected from each boring at the surface and 2-foot vertical intervals thereafter using a split-spoon sampling device. Each sample was placed in a 16-ounce glass jar and covered with a double layer of aluminum foil. Each sample was analyzed for petroleum hydrocarbons using an OVA in accordance with Chapter 62-770, FAC. In addition, soil samples were screened for benzene, toluene, ethylbenzene, and xylenes (BTEX) using a field GC. The results of the soil boring program are discussed in Section 5.1.

4.2 SOIL SAMPLING PROGRAM. Forty-five soil samples were collected from selected soil boring locations for laboratory analysis. Samples were collected directly from 2.25-inch solid-stem augers or from a split-spoon sampling device. Each sample was collected immediately above the water, generally from 3 to 6 feet bls. The samples were placed into appropriate containers, properly preserved, and shipped to EA Laboratories, Sparks, Maryland. Five samples were analyzed for the complete waste oil group list as described in Chapter 62-770, FAC. The remaining 41 soil samples were analyzed for arsenic, cadmium, chromium, lead, and TRPH as outlined in Chapter 62-770, FAC. Results of the soil sampling program are discussed in Section 5.1.

4.3 MONITORING WELL INSTALLATION AND CONSTRUCTION. During the CA, 91 shallow monitoring wells and 13 vertical extent wells were installed at the site (see Figure 4-2).

Borings in which monitoring wells were installed were advanced with 4.25-inch inside diameter (ID), hollow-stem augers. Split-spoon soil samples were collected at 2-foot vertical intervals until reaching the water table, after which, samples were collected at 5-foot intervals. Shallow monitoring wells were installed to depths ranging from 10 to 13 feet bls and were constructed of 2-inch ID, schedule 40, polyvinyl chloride (PVC) with 10 feet of 0.010-inch machine-slotted screen. The annular space around the screened interval was filled with a 20/30 grade silica filter pack to a depth approximately 1 foot above the top of the screen. An 8-inch thick bentonite seal was placed above the filter pack. The remaining annular space was grouted to land surface with portland cement.

NAVAL AIR STATION
KEY WEST, FLORIDA

Typical shallow monitoring well construction details are presented on Figure 4-3.

Double-cased deep monitoring wells were installed to a depth of 30 feet bls. Six-inch PVC surface casing extended to a depth of 20 feet bls. The wells were constructed of 2-inch ID, schedule 40, PVC with 5 feet of 0.010-inch machine-slotted screen. The annular space around the screened interval was filled with a 20/30 grade silica filter pack to a depth approximately 2 feet above the top of the screen. A 1-foot thick fine-sand seal was placed above the filter pack. The remaining annular space was grouted to land surface with portland cement. Typical deep monitoring well construction details are presented on Figure 4-4.

Monitoring wells were installed below grade in subsurface traffic-bearing vaults protected with metal manhole assemblies and 6-inch thick, 2-foot square concrete pads. Monitoring wells were fitted with a locking, watertight expansion plug.

Upon completion, monitoring wells were developed by pumping a minimum of five well volumes until the purged water was clear and relatively free of sediment.

4.4 WATER-LEVEL MEASUREMENTS. Depth to groundwater was measured and water table elevations were calculated for all site monitoring wells on April 16, 1996, and July 30, 1996. Depth to groundwater was measured to the nearest 0.01-foot using an electronic water-level indicator. Water table elevations were calculated by subtracting the measured depth to groundwater from the top of casing elevation for each respective well. Top-of-casing elevations were referenced to benchmarks located at the southeast corner of the Pier D-3/D-2 slip and the west end of Pier D-2. These benchmarks are part of the U.S. Army Corp of Engineers benchmarking system and have elevations of 5.98 and 13.16 feet, respectively, above the National Geodetic Vertical Datum of 1929. Water table elevation contour maps for each date were prepared using this information and are discussed in Section 5.6.

4.5 GROUNDWATER SAMPLING PROGRAM. Groundwater samples were collected from all site monitoring wells, except those containing free product, during the period April 2, 1996, through April 15, 1996. Before sampling, each monitoring well was purged using a low flow purging technique. Five well volumes were removed from each well. Groundwater samples for lead analysis were collected using Teflon™ and silicon tubing. The other sample parameters were collected using an extruded Teflon™ bailer. The samples were placed into appropriate containers, properly preserved, placed on ice, and shipped to EA Laboratories, Sparks, Maryland. Appropriate quality assurance and quality control samples were also collected and analyzed.

Samples were analyzed for either the constituents of the Kerosene or Waste Oil analytical groups, as defined in Chapter 62-770, FAC. The Kerosene analytical group samples were analyzed for volatile organic halocarbons by U.S. Environmental Protection Agency (USEPA) Method 601, for volatile organic aromatics (VOA) and methyl tert-butyl ether (MTBE) by USEPA Method 602, for polynuclear aromatic hydrocarbons (PAH) by USEPA Method 610, for ethylene dibromide (EDB) by USEPA Method 504, and for lead by USEPA Method 239.2. The waste oil analytical group samples were analyzed for volatile organics by USEPA Method 8240, semivolatiles

by USEPA Method 8270, TRPH by USEPA Method 418.1, and target analyte list metals (Arsenic, Cadmium, Chromium, and Lead). Laboratory analytical results of groundwater samples are discussed in Section 5.2.

4.6 SURFACE WATER AND SEDIMENT SAMPLING. Sediment and surface water samples were collected from 11 locations in Fleming Key Cut and the pier slips to evaluate the potential impact of the TPF site to the adjacent surface water and bottom sediments (see Figures 4-1 and 4-2). The 11 surface water samples were collected approximately 2 feet below the water surface using a beta bottle sampler. The sediment samples were collected with a sediment bomb sampler. Only six sediment samples were obtained because some locations yielded no sediments or only minor shell fragments in the sampler. All surface water and sediment samples were analyzed for Kerosene analytical group parameters by EA Labs, Sparks, Maryland. Sediment-sampling results are discussed in Section 5.3 and surface-water sampling results are discussed in Section 5.4.

4.7 HYDROGEOLOGIC ASSESSMENT. Water-level measurements were used to establish the direction of groundwater flow and provide data on fluctuations in the water table (see Section 5.6). In addition, a tidal influence study was conducted during a new moon phase to assess the effect of tides on the direction of groundwater flow, hydraulic gradient, and pore water velocity (see Section 5.7).

Aquifer tests were conducted to estimate the hydraulic properties of the water-table aquifer. Constant-rate pumping tests were performed to obtain hydraulic information due to the low horizontal conductivity in shallow and deep monitoring wells (see Sections 5.8 through 5.11).

5.0 CONTAMINATION ASSESSMENT RESULTS

5.1 SOIL CA.

5.1.1 OVA Headspace Data Soil assessment criteria follow Chapter 62-770, FAC, guidelines for the Kerosene analytical group. Soil with OVA headspace readings greater than 10 ppm, therefore, is considered to be petroleum contaminated. Soil with OVA headspace readings greater than 50 ppm is defined as "excessively contaminated." Excessively contaminated soil must be remediated in accordance with *Guidelines for Assessment and Remediation of Petroleum Contaminated Soils* (Florida Department of Environmental Regulation [FDER], May 1992).

All soil samples were collected above the water table, between 0 and 2 feet bls; between 2 and 4 feet bls; and between 4 and 6 feet bls. Soil samples collected between 4 and 6 feet bls were slightly above the water table. An activated charcoal filter was used during OVA headspace screening to measure the effect of methane on the total hydrocarbon concentration in the soil samples. Results of the 1993 and 1996 OVA headspace survey are presented in Appendix C, Soil Sample Organic Vapor Analyzer Headspace Results. The 1996 OVA headspace values listed in Table C, Appendix C were calculated by subtracting the filtered OVA reading from the unfiltered reading to obtain the concentration of petroleum hydrocarbons in the soil sample.

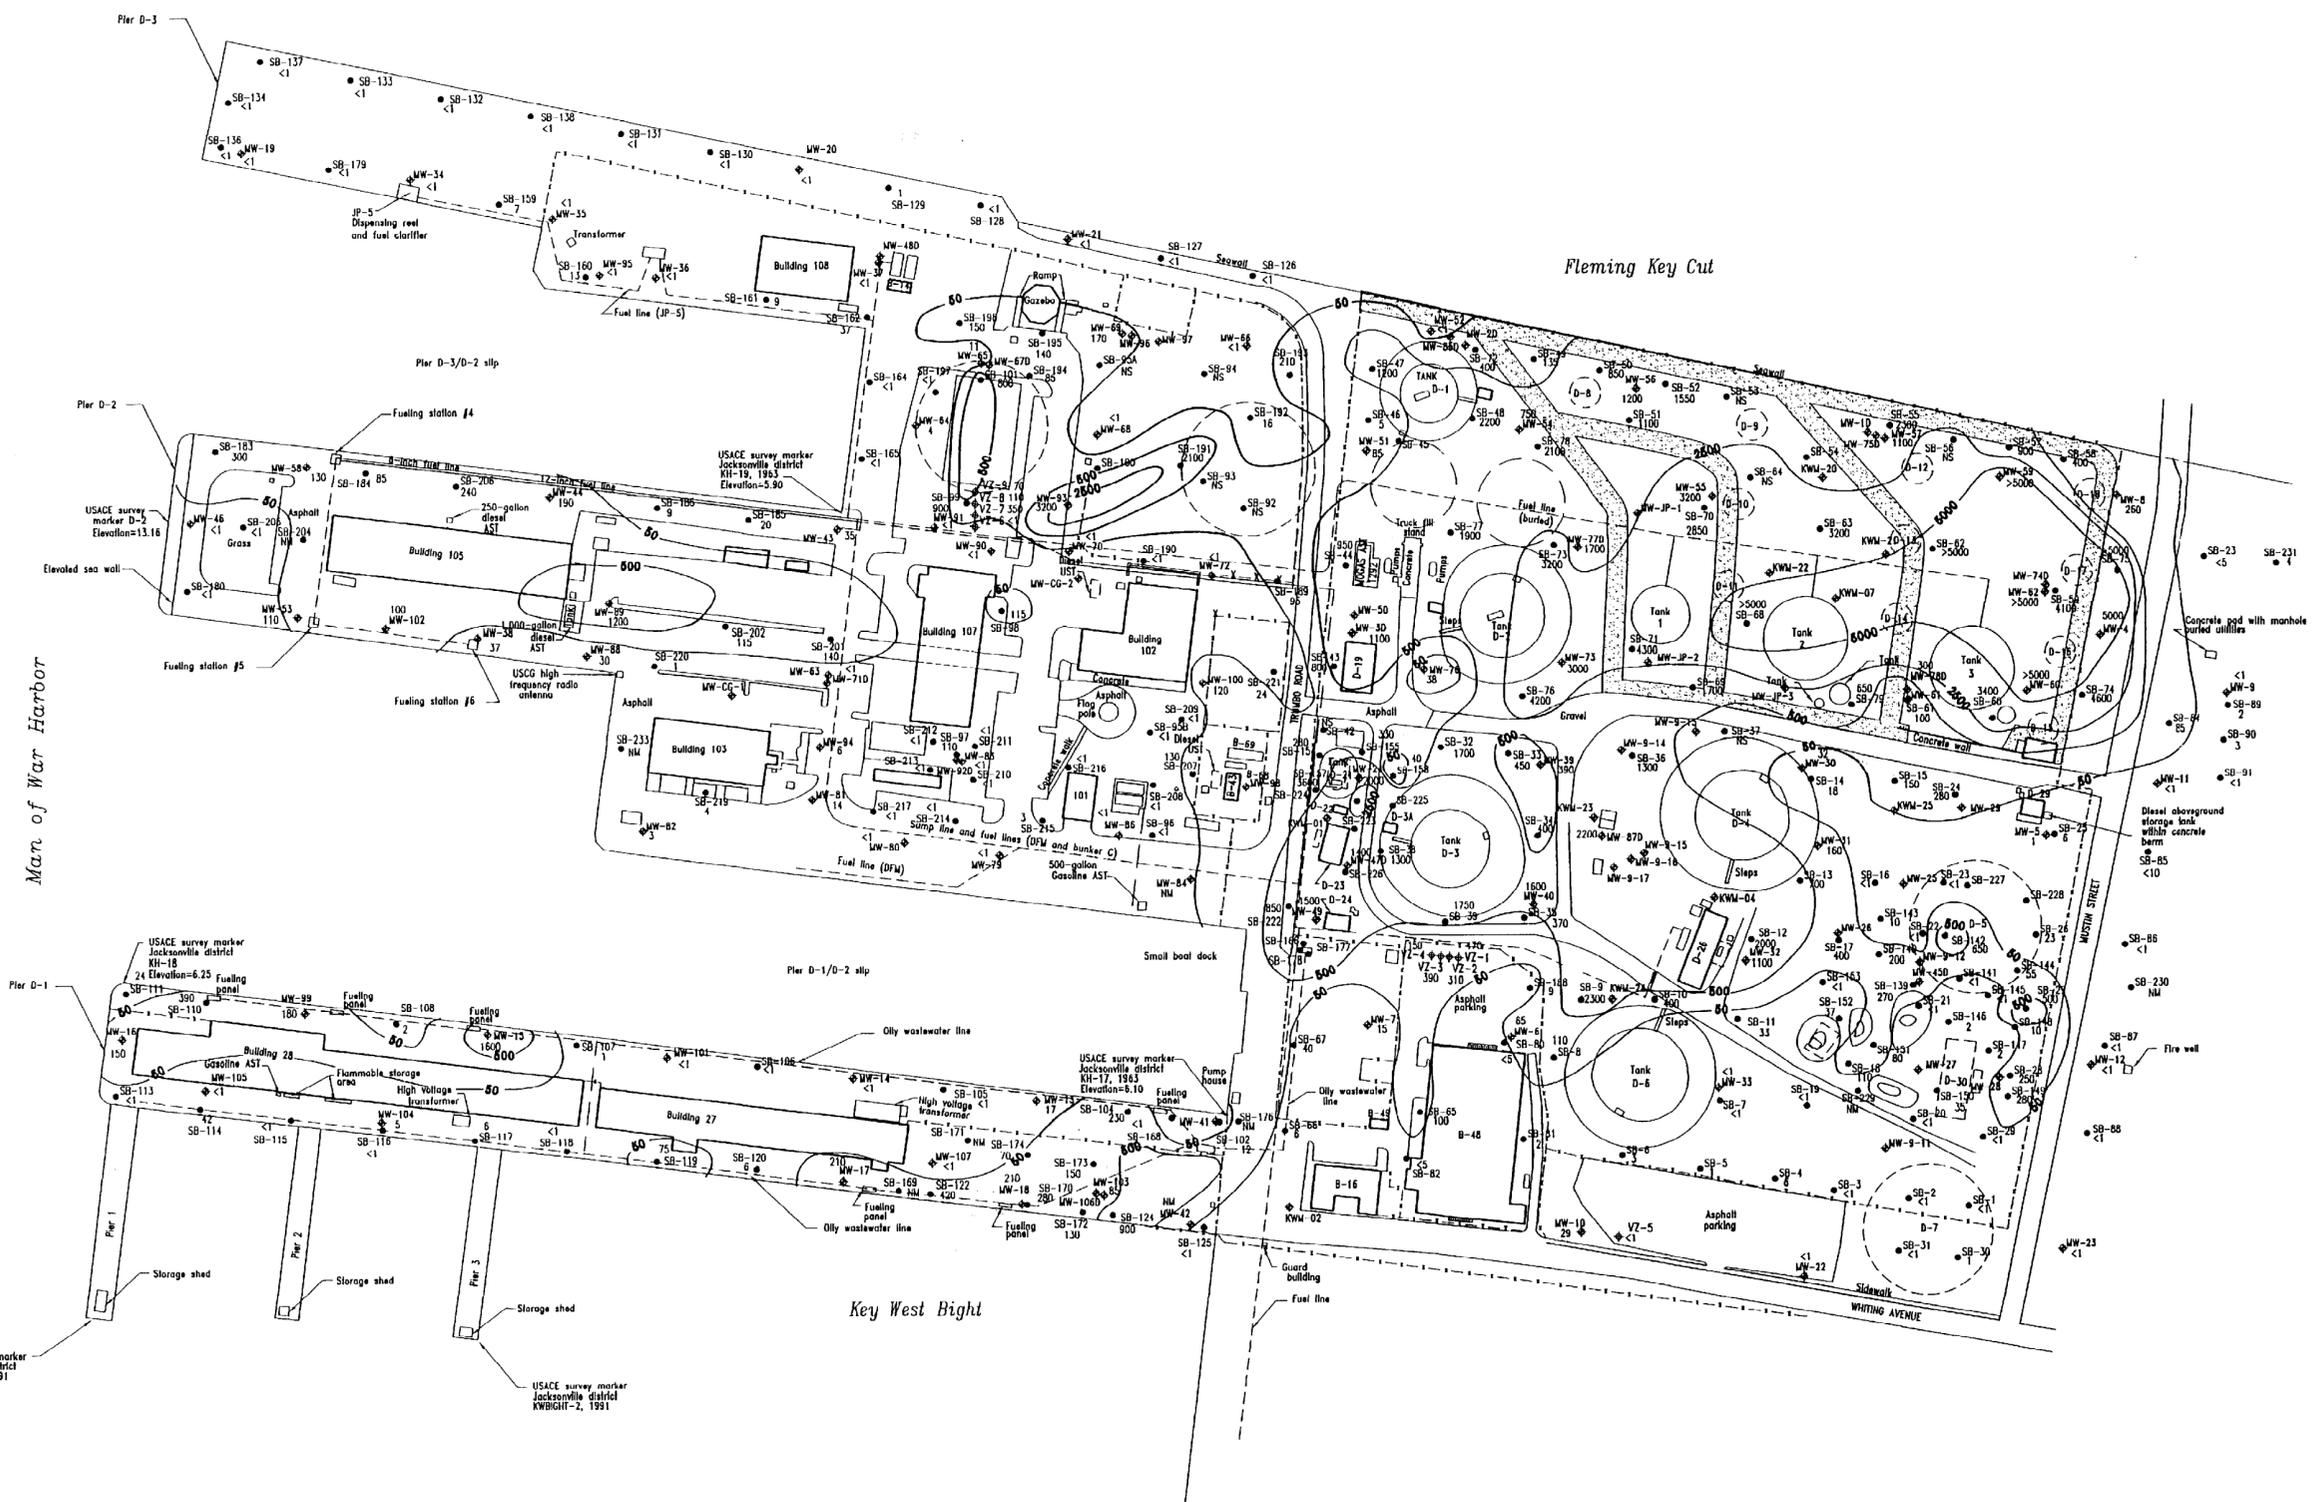

Figure 5-1 presents the area of excessively contaminated soil at the site. Contaminated soil was detected mostly between 4 and 6 feet bls. The areal extent of excessively contaminated soil is shown within the 50 ppm isoconcentration lines. Excessively contaminated soil was found throughout the TPF and portions of the USCG facility. The highest OVA readings (>2,500 ppm) were found in the vicinity of the three JP-5 tanks, DFM tank D-2, and the west side of the softball field.

The OVA data indicate that the areal extent of soil contamination appears to be delineated along the eastern and southern boundaries of the TPF. Petroleum-contaminated soil was not detected south of tank D-6 and Building B-48 in the southern part of the site. With the exception of soil boring SB-84, petroleum-contaminated soil was not detected east of Mustin Street. Excessively contaminated soil, however, was detected along the entire northern section of the TPF and was encountered over much of the western part of the site.

Excessively contaminated soil was also found at the USCG facility at the softball field, the basketball court, and the Pier D-2 area near Building 105. Excessively contaminated soil is present at both the east and west ends of Pier D-1 (see Figure 5-1).

Generally, the soil samples collected from the 0-2 feet bls and 2-4 feet bls intervals exhibited low OVA readings (less than 1 ppm) except for three areas which include a small area at the west end of Pier D-1, the area around tank D-21, and the area immediately west of tank D-4.

5.1.2 Soil Analytical Data Soil samples were collected from borings in the former tank D-5 area, the tank D-21 area, the oil-water separator area, and the area of the oil-water pump station on Pier D-1. The samples were obtained from a depth interval above the water table (approximately 4 feet bls). In each area, a source sample was analyzed for the complete waste-oil group parameters as

defined in Chapter 62-770, FAC. Delineation samples were collected and analyzed for TRPH and metals (arsenic, cadmium, chromium, and lead). Analytical laboratory results for the soil samples collected at the site, including equipment rinsate blanks and trip blanks, are summarized in Table 5-1 and attached as Appendix D, Soil Analytical Data.

Total VOAs were not detected in any source soil sample collected. Total PAHs exceeded the State maximum concentration of 1000 parts per billion (ppb) in two source area soil samples, sample 01B156 (east of tank D-21) and sample 01B167 (north of the oil-water pump station). Cadmium, chromium, lead, and arsenic concentrations were below the respective State maximum concentrations. TRPH concentrations greatly exceeded the State maximum concentration of 50 ppm in soil samples collected in the area of tank D-21, the oil-water pump station, the oil-water separator, and the area of former tank D-5.

Figure 5-2 presents TRPH concentrations detected in soil samples collected in these four areas. The extent of TRPH contamination has been assessed in the area of the pump station on Pier D-1 and over most of the former tank D-5 area. The area of the oil-water separator and tank D-21, while not fully assessed for TRPH, are within the 500 ppm OVA headspace area (see Figure 5-1) and will require remediation in accordance with Chapter 62-770, FAC.

On July 31, 1996, confirmation soil samples were collected at a depth of approximately 3.5 feet bls from soil boring locations SB-156 near tank D-21 and SB-229 near former tank D-5. The higher water table observed at this time (see Section 5-6), prevented collecting an unsaturated soil sample at a lower depth. In addition to these confirmation samples, soil samples were collected from soil borings SB-239 and SB-240 to assess the extent of TRPH contamination in soil south of soil boring SB-229.

The four confirmation samples were analyzed for TRPH using USEPA Method 418.1, FDEP Petroleum Range Organics (FL PRO), and Toxicity Characteristic Leaching Procedure (TCLP) with FL PRO. TRPH concentrations detected in these soil samples were SB-156 (30 ppm), SB-229 (420 ppm), SB-239 (1100 ppm), and SB-240 (less than 14 ppm). FL PRO concentrations detected in these soil samples were SB-156 (110 ppm), SB-229 (180 ppm), SB-239 (200 ppm), and SB-240 (less than 14 ppm). TCLP and FL PRO yielded no detections (less than 1 ppm) on leachates prepared from all of the samples.

5.2 GROUNDWATER CA. Groundwater analytical laboratory results for the sampling conducted at the site during March and April 1996, including equipment rinsate blanks and trip blanks, are presented in Table 5-2, Table 5-3, and Appendix E, Groundwater Sample Analytical Data. Table 5-2 presents the groundwater analytical results for the Kerosene analytical group samples only where compounds were detected. Table 5-3 presents the groundwater analytical results for the waste oil analytical group samples. It should be noted that higher method detection limits were reported for VOCs (5 ppb) and semivolatile organic compounds (10 ppb) for the waste-oil analytical group samples.

For petroleum compounds regulated under Chapter 62-770, FAC, Class G-II groundwater target levels will be used, where applicable. The following target level concentrations have been established in Chapter 62-770, FAC: benzene 1 ppb, total VOA (the sum of benzene, ethylbenzene, toluene, and xylenes) 50 ppb, TRPH 5 ppm, lead 50 ppb, total naphthalenes (the sum of naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene) 100 ppb, individual PAH 10 ppb or best achievable detection limit (excluding naphthalenes), EDB 0.02 ppb, and MTBE 50 ppb.

EDB was not detected in any groundwater sample collected at the site. MTBE was detected in only one groundwater sample collected from MW-52 at a concentration (3.5 ppb) well below the State target level of 50 ppb (see Table 5-2).

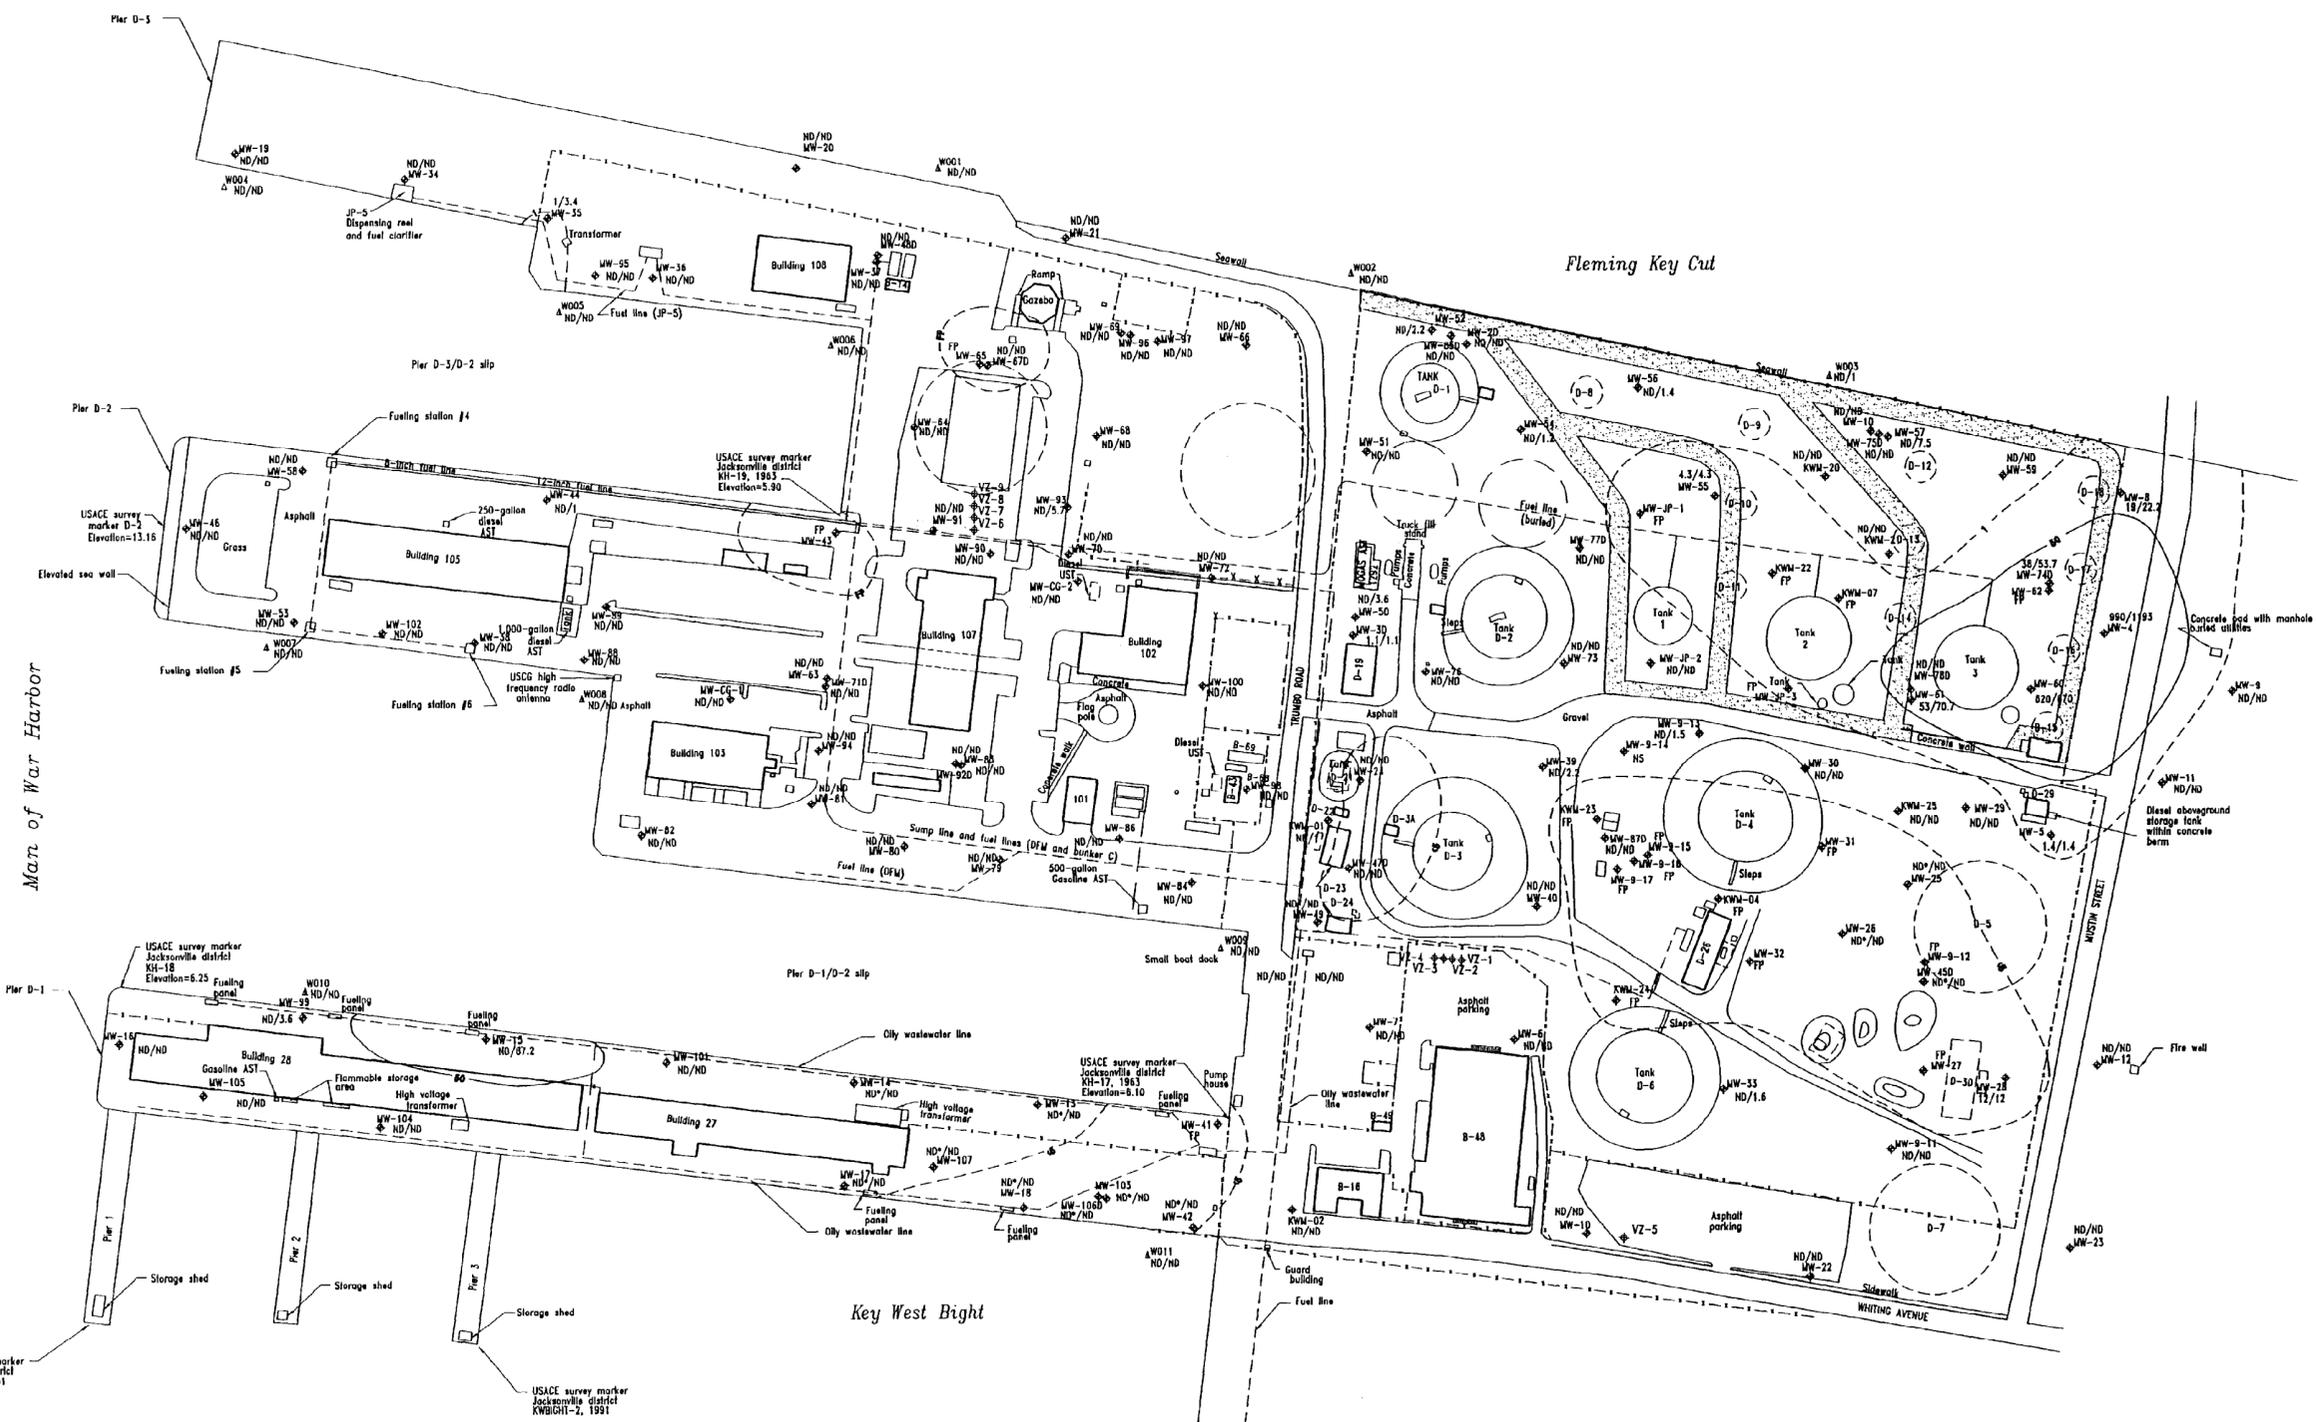

5.2.1 VOCs in Groundwater Several areas of petroleum-contaminated groundwater were assessed at the TPF and USCG. Presented on Figure 5-3 are total VOA concentrations in groundwater samples from wells in these areas, the areal extent of total VOA contamination, and the location of contaminant plume in relation to the tanks and integral pipes. Monitoring wells which contained free product were not sampled. Presented in Tables 5-2 and 5-3 are a summary of groundwater analytical data from well samples with detectable levels of BTEX, and their sum, total VOA.

Total VOA concentrations exceed the Chapter 62-770, FAC, target level for total VOA of 50 ppb in two areas at the site (see Figure 5-3). Total VOA concentrations greater than the State target level of 50 ppb were detected in groundwater samples collected from monitoring wells MW-4 (1,193 ppb), MW-15 (87.2 ppm), MW-60 (670 ppb), MW-61 (70.7 ppb), and MW-74D (53.7 ppb), which are located in the northeast area of the TPF. MW-74D is screened from 25 to 30 feet bls and is located approximately 7 feet north of MW-62, which is screened from 3 to 13 feet bls and contained free product. Monitoring wells that contained free-floating petroleum product, however, were not sampled and potentially represent areas that could exceed the State target level of 50 ppb for total VOA.

As part of an alternative procedure granted by FDEP to attempt to lower the VOA concentrations in monitoring well MW-74D, the well was pumped for 3 days starting on July 29, 1996, and resampled on August 2, 1996. Total VOA concentration increased slightly to 66.6 ppb with benzene (57 ppb), ethylbenzene (3.1 ppb), and xylenes (6.5 ppb).

Total VOA concentrations greater than the State target level of 50 ppb were not detected in groundwater samples from the other deep monitoring wells at the site. The total VOA concentration in the sample from MW-1D, which is screened from 40 to 45 feet bls, was 1.1 ppb.

Benzene. Presented on Figure 5-3 are the benzene concentrations in groundwater and the 1 ppb isoconcentration contour line for benzene in groundwater beneath the site. The 1 ppb benzene isoconcentration line overlaps the total VOA isoconcentration line and is generally located in the same area. The highest benzene concentrations were detected in groundwater samples collected from monitoring wells MW-4 (990 ppb), MW-60 (620 ppb), MW-61 (53 ppb), and MW-74D (38 ppb), which coincide with the areas of highest observed soil contamination. High benzene concentrations were also detected in MW-28 (12 ppb) in the former tank D-5 area. Monitoring wells that contained free-floating petroleum product,

NAVAL AIR STATION
KEY WEST, FLORIDA

however, were not sampled and potentially represent areas that could exceed the State target level of 1 ppb for benzene. Laboratory analytical results of groundwater samples with detectable levels of benzene are presented in Tables 5-2 and 5-3.

Chlorinated Compounds. Several chlorinated compounds were detected in the groundwater samples collected from monitoring wells MW-15, MW-28, MW-61, MW71D, MW-79, MW-92D, MW-94, MW-99, and MW-102 at concentrations ranging from 1.0 to 6.5 ppb (see Tables 5-2 and 5-3). Compounds detected included 1,1-dichloroethane, 1,2 dichlorobenzene, bromodichloromethane, bromoform, dibromochloromethane, trichloroethene, and trichlorofluoromethane. The source of these compounds is not known; however, several of these compounds are commonly used as solvents or degreasing agents and may have been used at the site in the past. Bromodichloromethane, bromoform, and dibromochloromethane were also detected at similar concentrations in equipment rinsate blanks 01R005 and 01R006 (see Tables 5-2 and 5-3) and may have been introduced as contaminants by the laboratory that analyzed the samples.

5.2.2 PAHs in Groundwater PAHs were detected in samples collected from monitoring wells MW-1, MW-2, MW-4, MW-5, MW-6, MW-7, MW-12, and MW-15 (see Figure 5-4). PAH detected in groundwater samples include naphthalene, 1-methylnaphthalene, 2-methylnaphthalene, acenaphthene, acenaphthylene, anthracene, fluoranthene, and fluorene. Tables 5-2 and 5-3 summarize the laboratory data for samples with detectable levels of PAH.

Naphthalenes. Total naphthalene concentrations exceeded the Chapter 62-770, FAC, Class G-II groundwater target level of 100 ppb in the samples collected from monitoring wells MW-15 (174 ppb), MW-50 (196 ppb), MW-55 (1750 ppb), and MW-60 (182 ppb). Monitoring wells that contained free product were not sampled and potentially exceed the State target level of 100 ppb for total naphthalenes. The areal extent of total naphthalenes in groundwater exceeding the State target level of 100 ppb is approximated by the 100 ppb isoconcentration line on Figure 5-4.

Laboratory results of the groundwater sample collected from deep monitoring well MW-74D (19.2 ppb) indicate the vertical extent of PAH (including naphthalenes) above Chapter 62-770, FAC, target levels in groundwater does not extend below 25 feet bls.

Nonnaphthalenes. Nonnaphthalene PAHs detected in groundwater samples collected from monitoring wells onsite included acenaphthene, acenaphthylene, anthracene, fluoranthene, and fluorene (see Table 5-2). The Chapter 62-770, FAC, target level for nonnaphthalene PAHs is 10 ppb or the lowest obtainable detection limit for each compound. Acenaphthene concentrations detected in MW-55 (63 ppb), MW-86 (17 ppb) and KWM-01 (37 ppb) exceeded the Chapter 62-770, FAC, target level. Acenaphthylene concentrations detected in MW-55 (120 ppb) and MW-74D (11 ppb) exceeded the Chapter 62-770, FAC, target level. Fluorene concentrations detected in MW-3 (76 ppb), MW-4 (17 ppb) and KWM-20 (26 ppb) exceeded the Chapter 62-770, FAC, target level.

5.2.3 Base, Neutral, and Acid (BNA) Extractables in Groundwater BNA extractables were detected in three of the groundwater samples analyzed for the waste-oil group parameters. Monitoring wells in which BNA extractables were detected included MW-17 (Phenol 15 ppb), MW-18 (Phenol 92 ppb and 2,4 - Dimethylphenol 54 ppb), and MW-42 (Phenol 43 ppb and bis(2-Ethylhexyl)phthalate 4 ppb) (see Table 5-3).

5.2.4 TRPH in Groundwater TRPH were detected in groundwater samples collected from monitoring wells MW-1D, MW-15, MW-40, MW-42, MW-55, MW-57, MW-64, MW-86, MW-91, KWM-01, KWM-20 and KWM-21 (see Figure 5-5). Presented in Tables 5-2 and 5-3 is a summary of all TRPH concentrations detected in groundwater samples collected from all of the monitoring wells at the site. Three areas of TRPH contamination in groundwater exceeding the Chapter 62-770, FAC, target level of 5 ppm were identified. Concentrations of TRPH in samples collected from monitoring wells MW-55 (157 ppm), MW-86 (5.1 ppm) and KWM-01 (15.7 ppm) exceed the Chapter 62-770, FAC, target level of 5 ppm for TRPH.

Monitoring wells that contained free-floating petroleum product, however, were not sampled and potentially represent areas that could exceed the State target level of 5 ppm for TRPH. The horizontal and vertical extent of free product at the site is discussed in Section 5.5, Free-Product Assessment.

Groundwater analytical data indicate the vertical extent of TRPH in groundwater is less than 40 feet bls. TRPH was detected in the groundwater sample collected from the vertical extent monitoring well MW-1D (1.1 ppm).

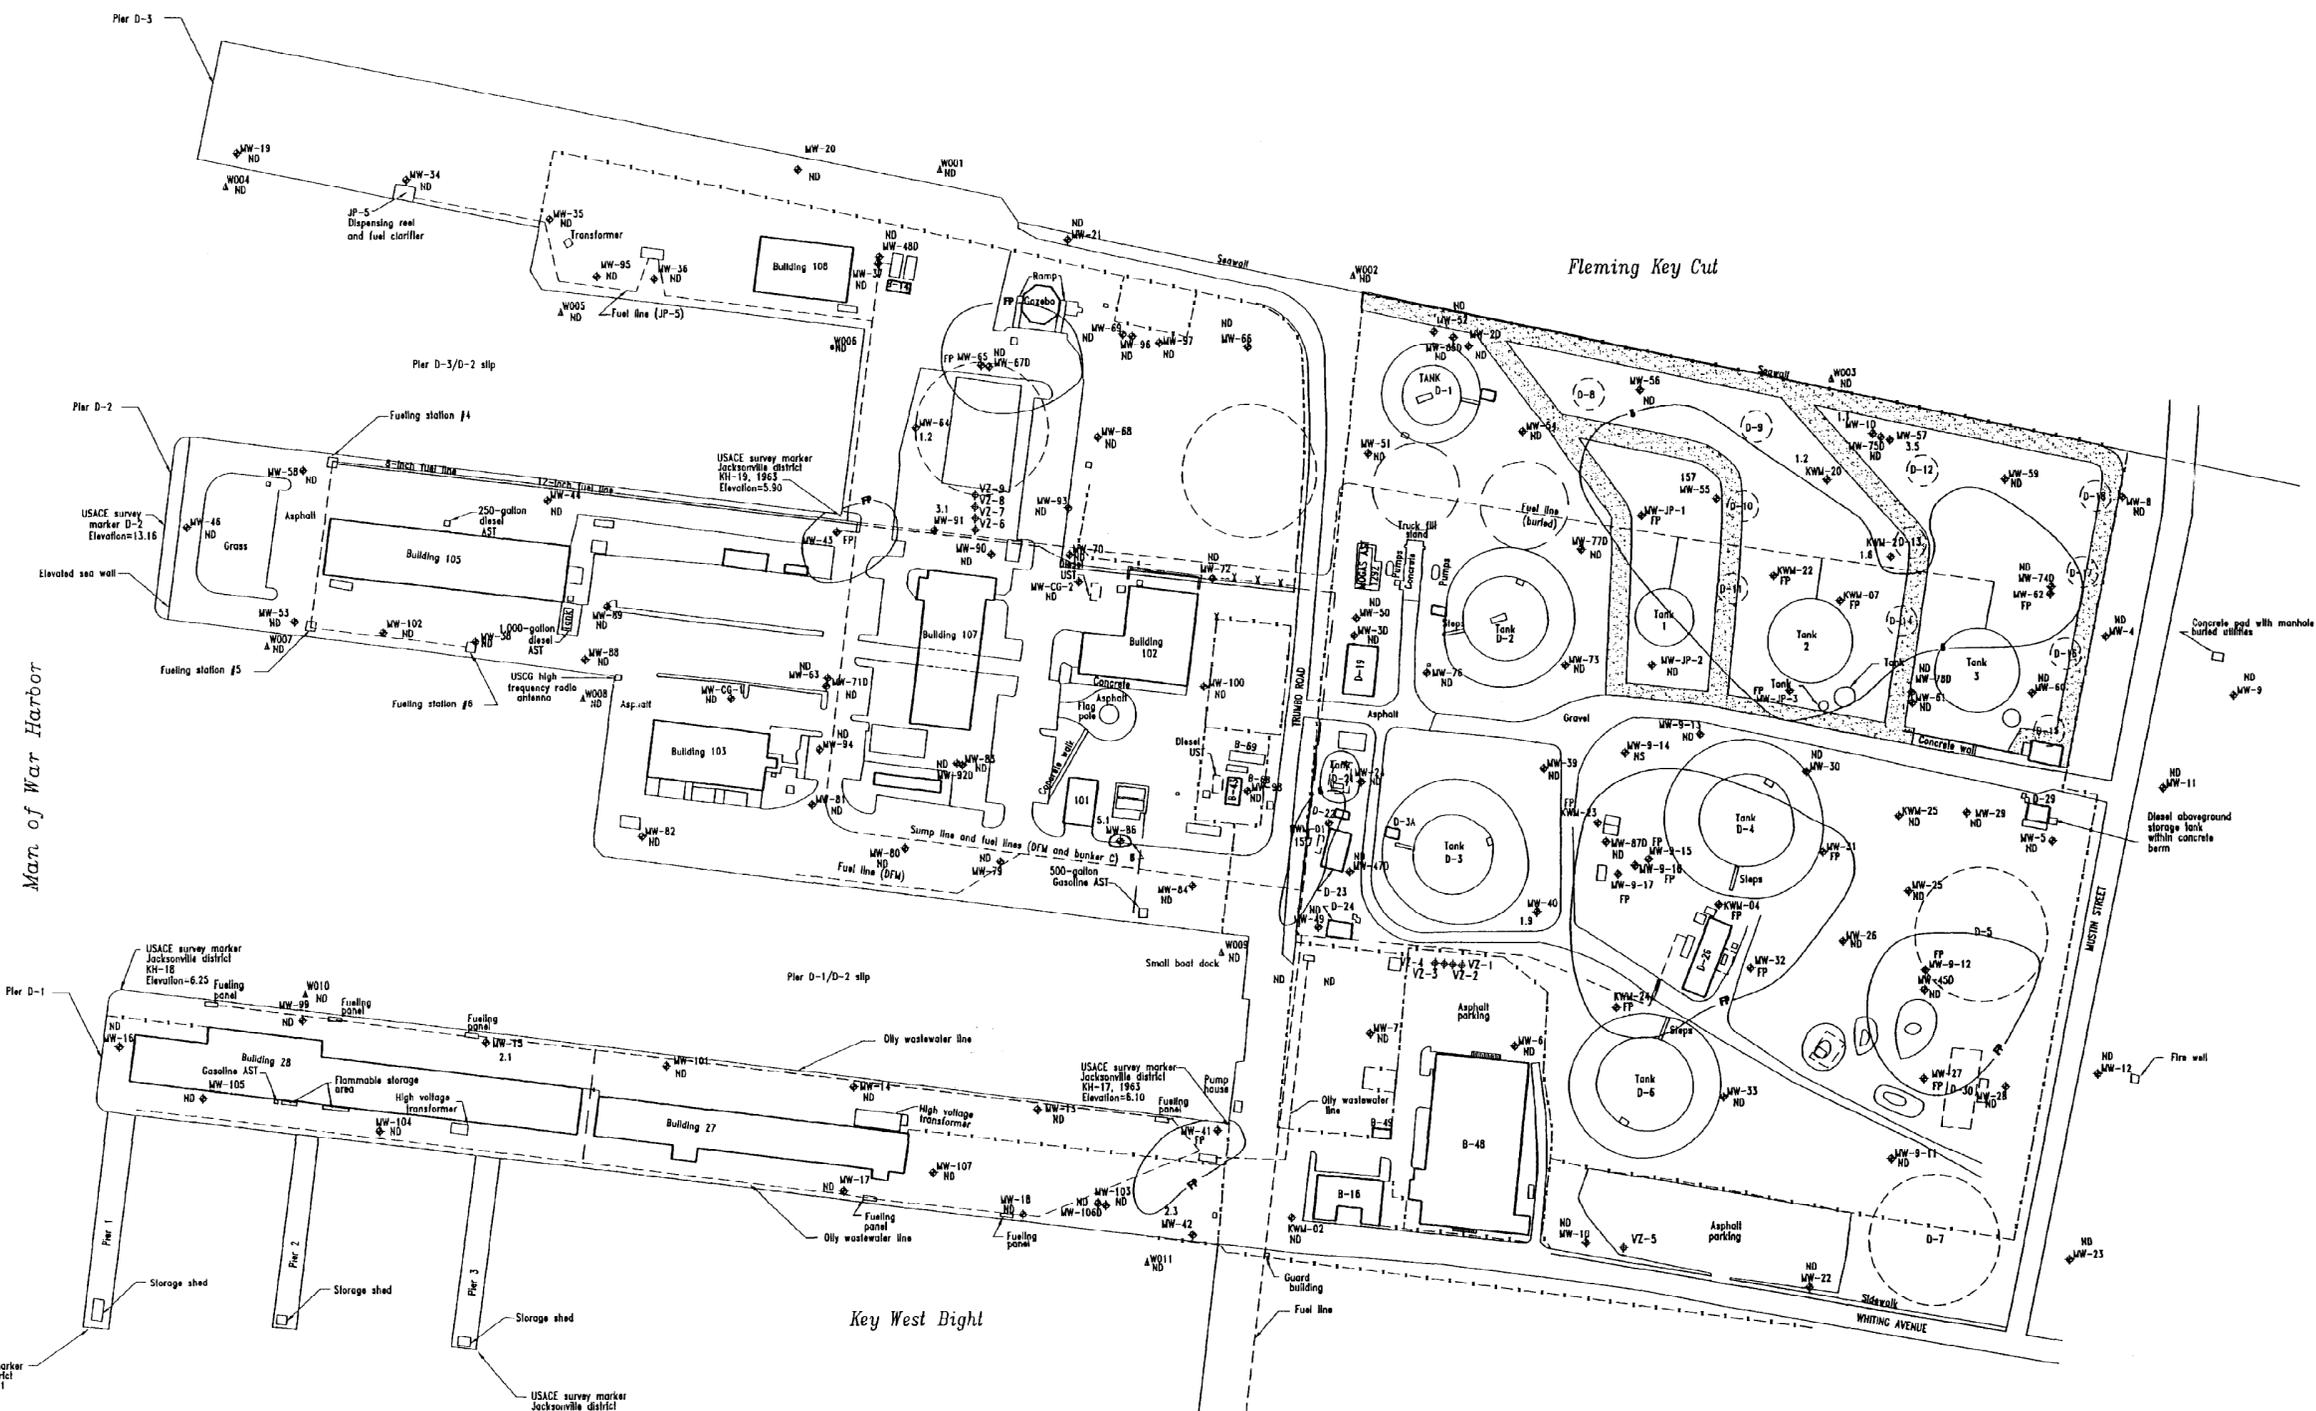

5.2.5 Metals in Groundwater Groundwater samples collected from all monitoring wells on the site were analyzed for lead, and in the case of the waste-oil group samples, for arsenic, chromium, and cadmium. Lead was detected in groundwater samples collected from monitoring wells MW-6, MW-55, MW-63, MW-64, MW-73, MW-96, KWM-01, KWM-02 and KWM-20 in concentrations ranging from 1.2 ppb to 12 ppb (see Tables 5-2 and 5-3), which do not exceed the Chapter 62-770, FAC, target level of 50 ppb for Class G-II groundwater.

The monitoring wells were purged using low-flow techniques and the sample turbidity ranged from 0.33 to 190.1 nephelometric turbidity units. Lead in groundwater is not considered to be a contaminant of concern at the site. Arsenic, chromium, and cadmium were not detected in any groundwater sample analyzed for the waste-oil group parameters (Table 5-3).

5.3 SEDIMENT CA. Analytical laboratory results for sediment samples collected in the surface water adjacent to the site are presented in Table 5-4 and Appendix F. The samples were collected at six locations in Man of War Harbor adjacent to the pier. The samples were analyzed for the Kerosene analytical group to evaluate the potential impact of the site to the surrounding waters. The sediment samples consisted of fine-grained oolitic lime mud with some shell fragments and were very light gray in color. No sediments were recovered from sampling locations D001, D002, and D004. Sampling locations D003 and D007 were not accessible for sampling. Figure 4-1 shows the sample locations.

The sediment sample analytical data indicate no detections above the detection limit for USEPA Methods 601, 602 and EDB; however, elevated concentrations of PAH, TRPH, and lead were detected in some or all of the samples. Target levels are applied using the standards for clean soil as defined in Chapter 62-775.400, FAC.

Lead concentrations detected in the sample from location D008 (732 ppm) exceeded the State target level of 108 ppm. Total PAH concentrations detected from sample locations D008 (3,360 ppb) and D009 (2,030 ppb) exceeded the State target level

of 1,000 ppb. TRPH concentrations detected from all sediment samples collected, D005 (244 ppm), D006 (169 ppm), D008 (519 ppm), D009 (244 ppm), D010 (184 ppm), and D011 (1860 ppm), exceeded the State target level of 50 ppm (see Table 5-4).

The source of PAH, TRPH, and lead contamination in surface water sediment may be attributed to past oil seepage, bilge water discharges, and particles of lead-base paint from naval vessels operating at the facility.

5.4 SURFACE WATER CA. Analytical laboratory results of surface water samples collected in Fleming Key Cut and Man of War Harbor are presented in Table 5-4 and Appendix F. The sampling locations and results are included on Figures 5-3, 5-4, and 5-5 with the groundwater data. No compounds were detected in any of the surface water samples collected except for toluene (1 ppb) in sample W003 and methylene chloride (3.9 ppb) in sample W011. It is likely these compounds are attributed to activities associated with boats and ships docked at the site.

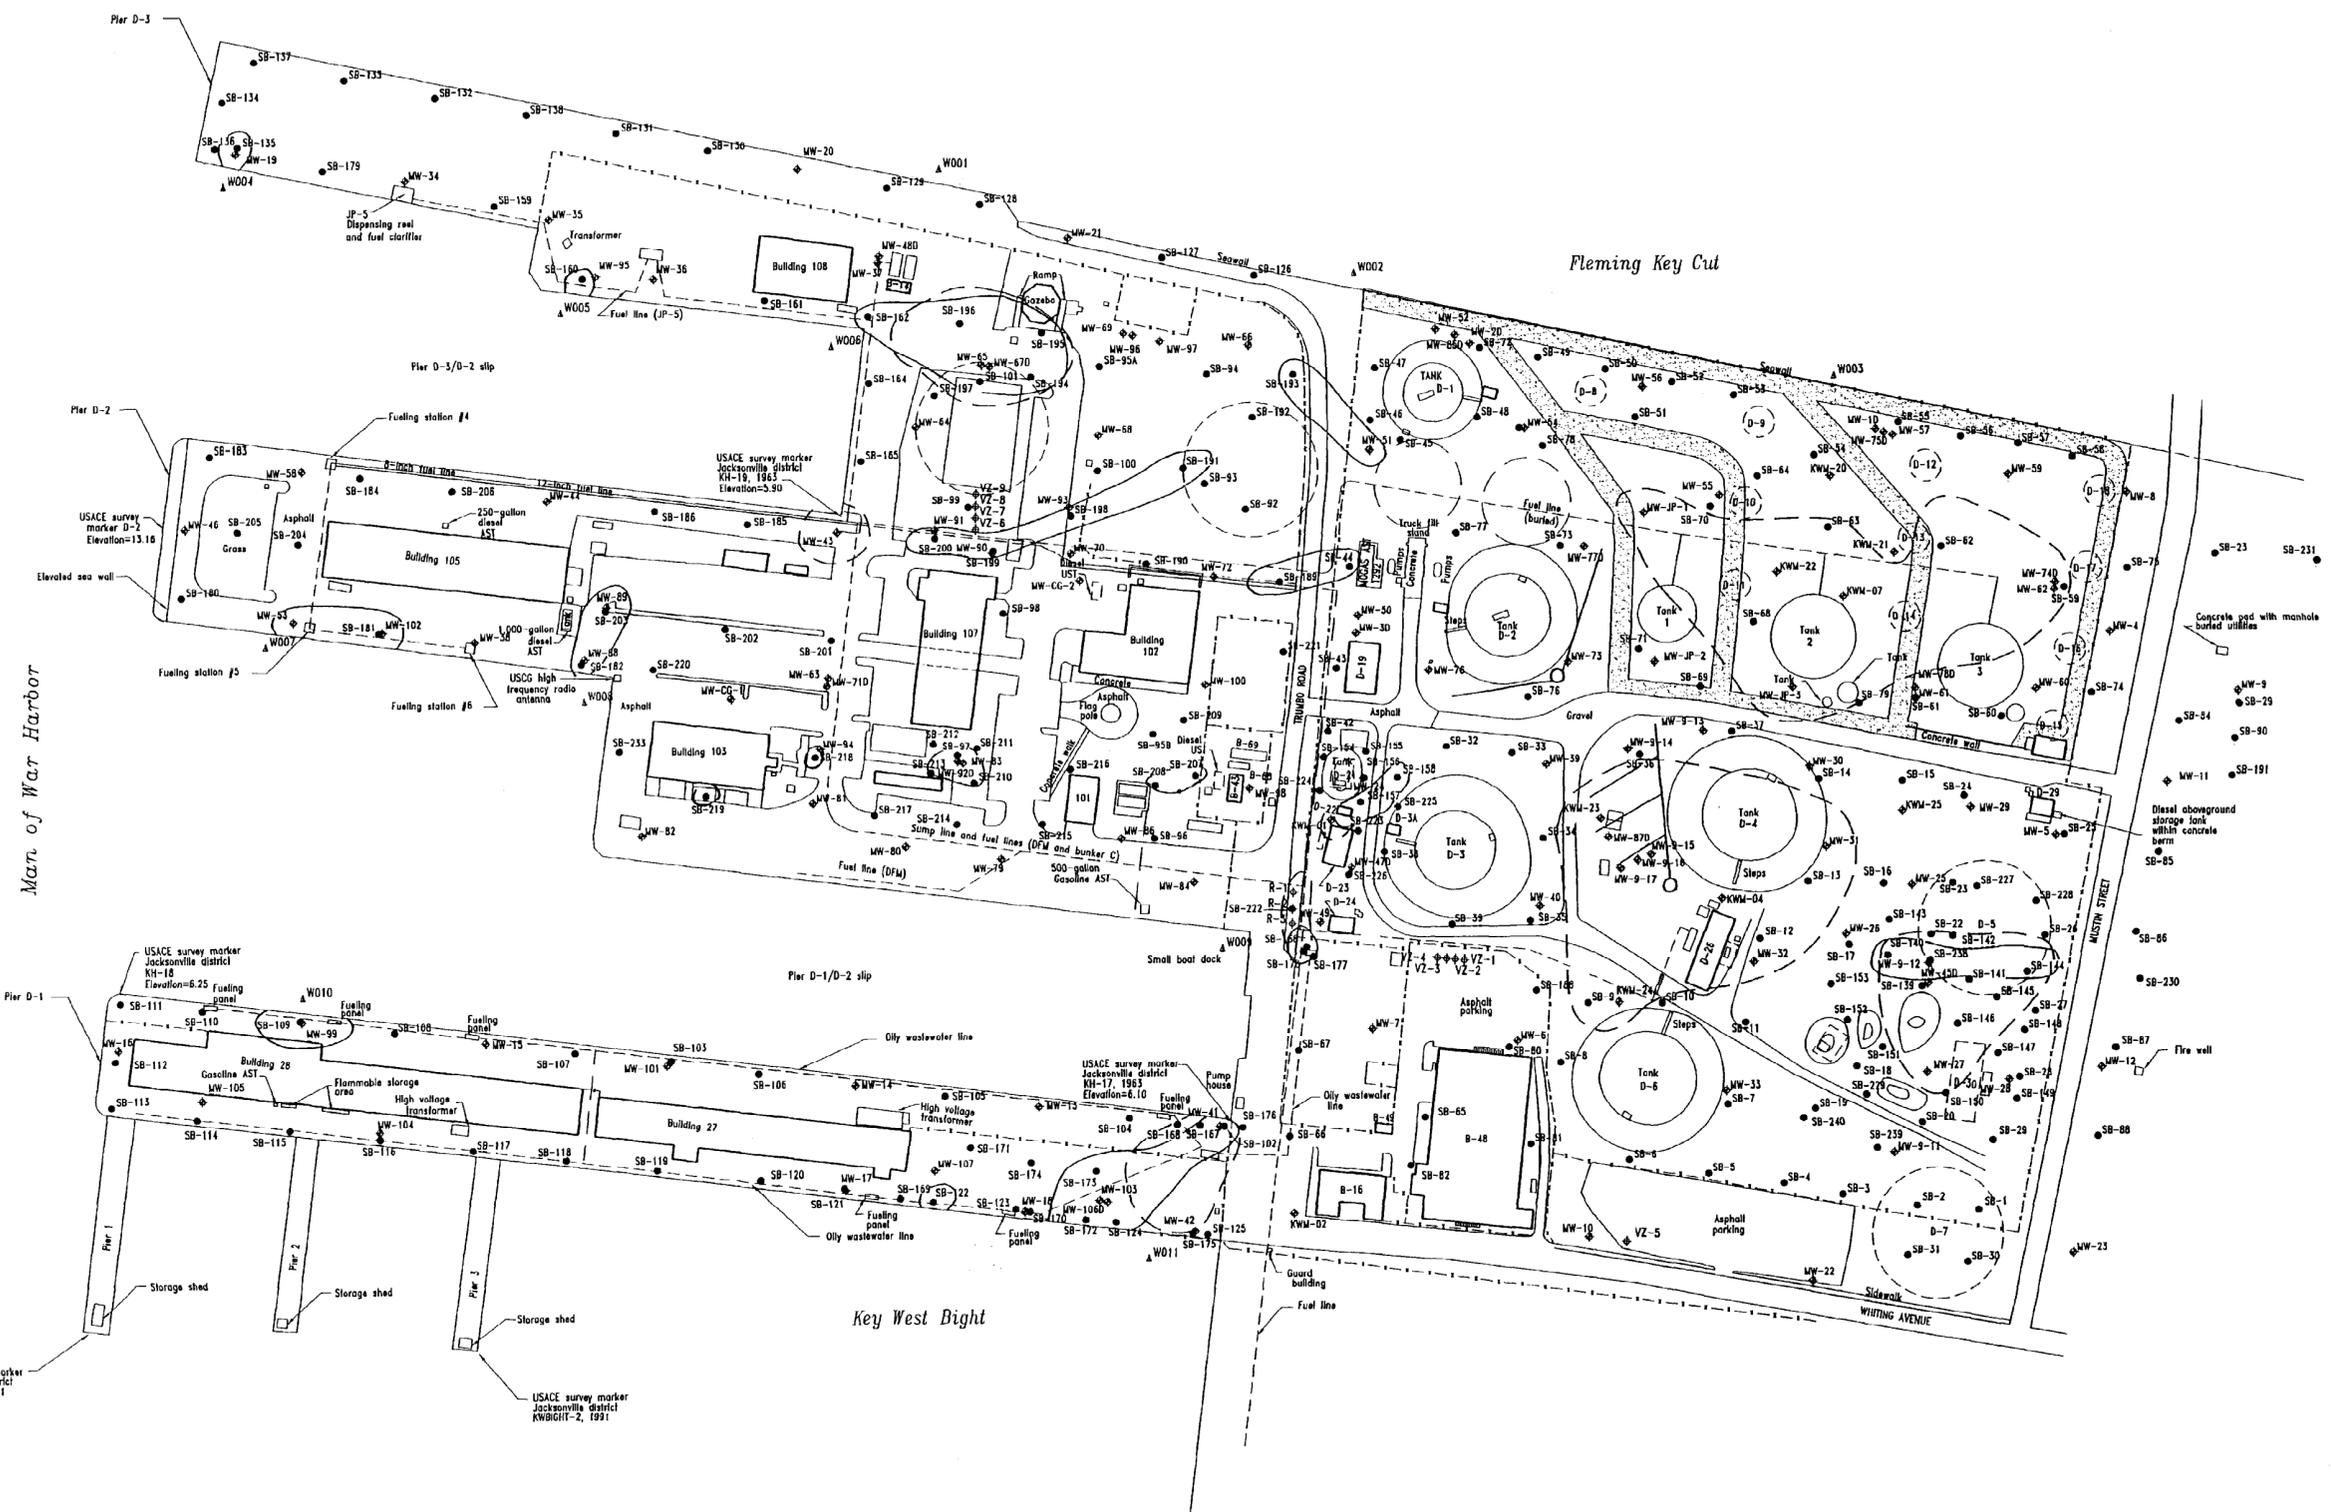

5.5 FREE-PRODUCT ASSESSMENT. During the 1993 PCA, free product was detected in monitoring wells KWM-07, KWM-22, KWM-23, KWM-24, MW9-10, MW9-12, MW9-13, MW9-15, MW9-17, MW-JP-1, and the fire well located southwest of DFM tank D-2. Viscous free product having a consistency similar to tar was detected in SB-44 (located near the MOGAS AST), the underground JP-5 pipeline, and an abandoned Bunker-C oil pipeline. Viscous free product was also detected in soil boring SB-101, located near the basketball court at the USCG facility.

The 1993 PCA showed an extensive area of free product in soil borings and monitoring wells in the northern part of the TPFf around JP-5 tanks 1, 2, and 3 and DFM tank D-2. The free product, however, did not extend to the seawall. Free product was observed in three other areas of the TPFf: the area along the south and west sides of DFM tank D-4; an area in the vicinity of the former DFM and waste oil tank D-5, near monitoring well MW9-12; and an area surrounding monitoring well KWM-01, which was previously reported to contain free product (Geraghty & Miller, 1987). Free product appeared to extend west from the TPFf toward the USCG facility, but was not assessed further in that direction. Free product was also encountered at the USCG facility in SB-101, north of the basketball court.

In January 1996, Bechtel began installing a gravel trench recovery system with sumps to remove free product in the vicinity of tanks D-2 and D-4. The approximate location of the trenches and sumps are shown on Figure 5-6.

During the CA free product was observed in a number of soil borings. Table 5-5 presents a characterization of observed free product during soil boring or monitoring well installation. After monitoring well installation was completed, free-product thickness measurements were recorded in all monitoring wells during the water-level elevation survey conducted on April 16, 1996, and July 30, 1996. Table 5-6 presents the apparent thickness of free product measured in each monitoring well where free product was observed.

Figure 5-6 presents the distribution of free product observed in soil borings and monitoring wells at the site. In some areas, free product observed in borings

KWM-24	2.27	0.36

¹ Product in this well has very high viscosity. Oil-water interface probe was damaged during initial product measurement in this well.

Notes: NM = not measured.
TR = less than 0.01 foot.
NP = no product observed.

was not observed in monitoring wells installed later at those locations. Product occurrence and apparent thickness observed in the monitoring wells are apparently influenced by product viscosity and seasonal fluctuations of the water table.

Lower-viscosity product likely migrates into monitoring wells more quickly than high viscosity product types, which may explain why product observed in soil borings was not observed later in monitoring wells at the same location.

A low viscosity, gold to amber color, product was observed in the area north of the JP-5 tanks and the area west of tank D-4. A high viscosity black color product was observed in the former tank D-5 area.

Low to medium viscosity black degraded product was observed in the area of the oily wastewater pump station on pier D-1, along the fuel lines on piers D-2 and D-3, and the area west of tank D-3 near Trumbo Road.

Low to medium viscosity, amber to brown color, product was observed in the vicinity of the basketball court at the USCG facility. A tar-like black color product was observed in soil borings near the softball field and south of the basketball court (see Figure 5-6).

In 10 of the 18 monitoring wells with free product, a reduction in the apparent thickness was observed when the water table was higher on July 30, 1996 (see Table 5-6). Six monitoring wells, however, exhibited no change or a slight increase in the measured apparent free-product thickness. One monitoring well (MW9-12) was not measured on either of the survey dates because of the high viscosity of the product (see Table 5-6).

5.6 GROUNDWATER ELEVATION SURVEY. Depth to water beneath the site is typically between 4 and 6 feet bls. Depth-to-water measurements were recorded on two occasions during the CA field investigation. Presented in Table 5-7 are top-of-casing elevations, depth-to-water measurements, and water table elevations recorded on April 16, 1996 and July 29, 1996. Water table elevation contour maps for these dates are presented on Figures 5-7 and 5-8, respectively. Also presented in Table 5-7 is the total depth and screened interval of each monitoring well.

Groundwater elevation data indicate that groundwater has been consistently flowing radially away from the fuel farm and in a northwest direction. The data was collected during a 3-month time frame during both dry and wet periods of the spring and summer seasons. The recorded shallow water table elevations are approximately 0.50 foot higher in July 1996 than in April 1996.

Comparison of shallow monitoring well water-elevation data and the deeper monitoring well data indicate mostly an upward vertical hydraulic gradient; however, the monitoring wells located on the east side of Pier D-1 and the monitoring wells north of Building D-19 exhibited a downward vertical hydraulic gradient (see Table 5-7 and Figures 5-7 and 5-8).

NAVAL AIR STATION
KEY WEST, FLORIDA

5.7 TIDAL INFLUENCE STUDY.

5.7.1 Purpose and Scope A tidal influence study was conducted to assess the effect of tidal fluctuations on groundwater elevations and flow direction at the site. The study was conducted during a 39-hour period to record one or more tidal cycles when tidal fluctuations were near maximum levels.

5.7.2 Background The tide is the periodic rise and fall of the Earth's water resulting from gravitational interactions between the Sun, Moon, and Earth. There are generally two high and two low waters in a day. Tides follow the Moon more closely than they do the Sun, and the lunar or tidal day is about 50 minutes longer than the solar day. When the two high waters and two low waters of each tidal day are approximately equal in height, the tide is said to be semidiurnal. When there is a relatively large diurnal inequality in the high or low waters or both, the tide is said to be mixed. Finally, when there is only one high water and one low water in each tidal day, the tide is said to be diurnal.

When water is falling or moving away from a shoreline, the tide is said to be an ebb tide. Under conditions when water is rising, the tide is said to be a flood tide. The time and heights of the rising and falling of the tide can be predicted based on our knowledge of gravitational interactions. Daily tide predictions in the United States are available and are based upon analyses of tidal observations for periods of at least 1 year. Extreme meteorological conditions are excluded from the analyses and predictions; therefore, the predicted tidal heights are those expected under average weather conditions. Prolonged onshore winds or low barometric pressure can produce higher tidal levels than predicted. In addition, prolonged offshore winds or high barometric pressure can produce lower tidal levels than predicted.

Exclusive of weather conditions, the astronomical tide is also subject to range variations. Decreased ranges may be expected near the times when the Moon is in apogee (farthest from the Earth) or in quadrature (angular separation of the Moon and Sun from the Earth is 90 degrees; also called Neap tides). Increased ranges may be expected when the Moon is in perigee (nearest to Earth in its orbit) or in a new or full position (spring tides). A larger diurnal range may also result when the Moon is in its maximum declination (tropic tides). The actual tidal range will depend upon the extent to which combinations of these positions reinforce or detract from one another. These range variations based on astronomical conditions are included in the daily tide predictions.

Groundwater aquifers that are in hydraulic connection with surface water bodies such as rivers, lakes, oceans, etc., are influenced by fluctuations of the water bodies. These fluctuations may be the result of tidal influences, flooding, rainfall, or the influence of manmade control structures such as dams and locks. During high surface water conditions the aquifer may be recharged, whereas, during low surface water conditions the aquifer will usually discharge into the surface water body. In a groundwater aquifer, the effects of surface water fluctuations will diminish with distance from the source (river, ocean, etc.).

The Lower Keys, including Key West, are overlain by an oolitic member of the Pleistocene Miami Limestone, except in those areas where fill material has been imported. Overlying the oolite to a depth approximately 10 feet bls is a clayey calcareous fill material dredged from the channel bottom of Fleming Key Cut. The surficial aquifer is contained within the fill material and oolitic limestone.

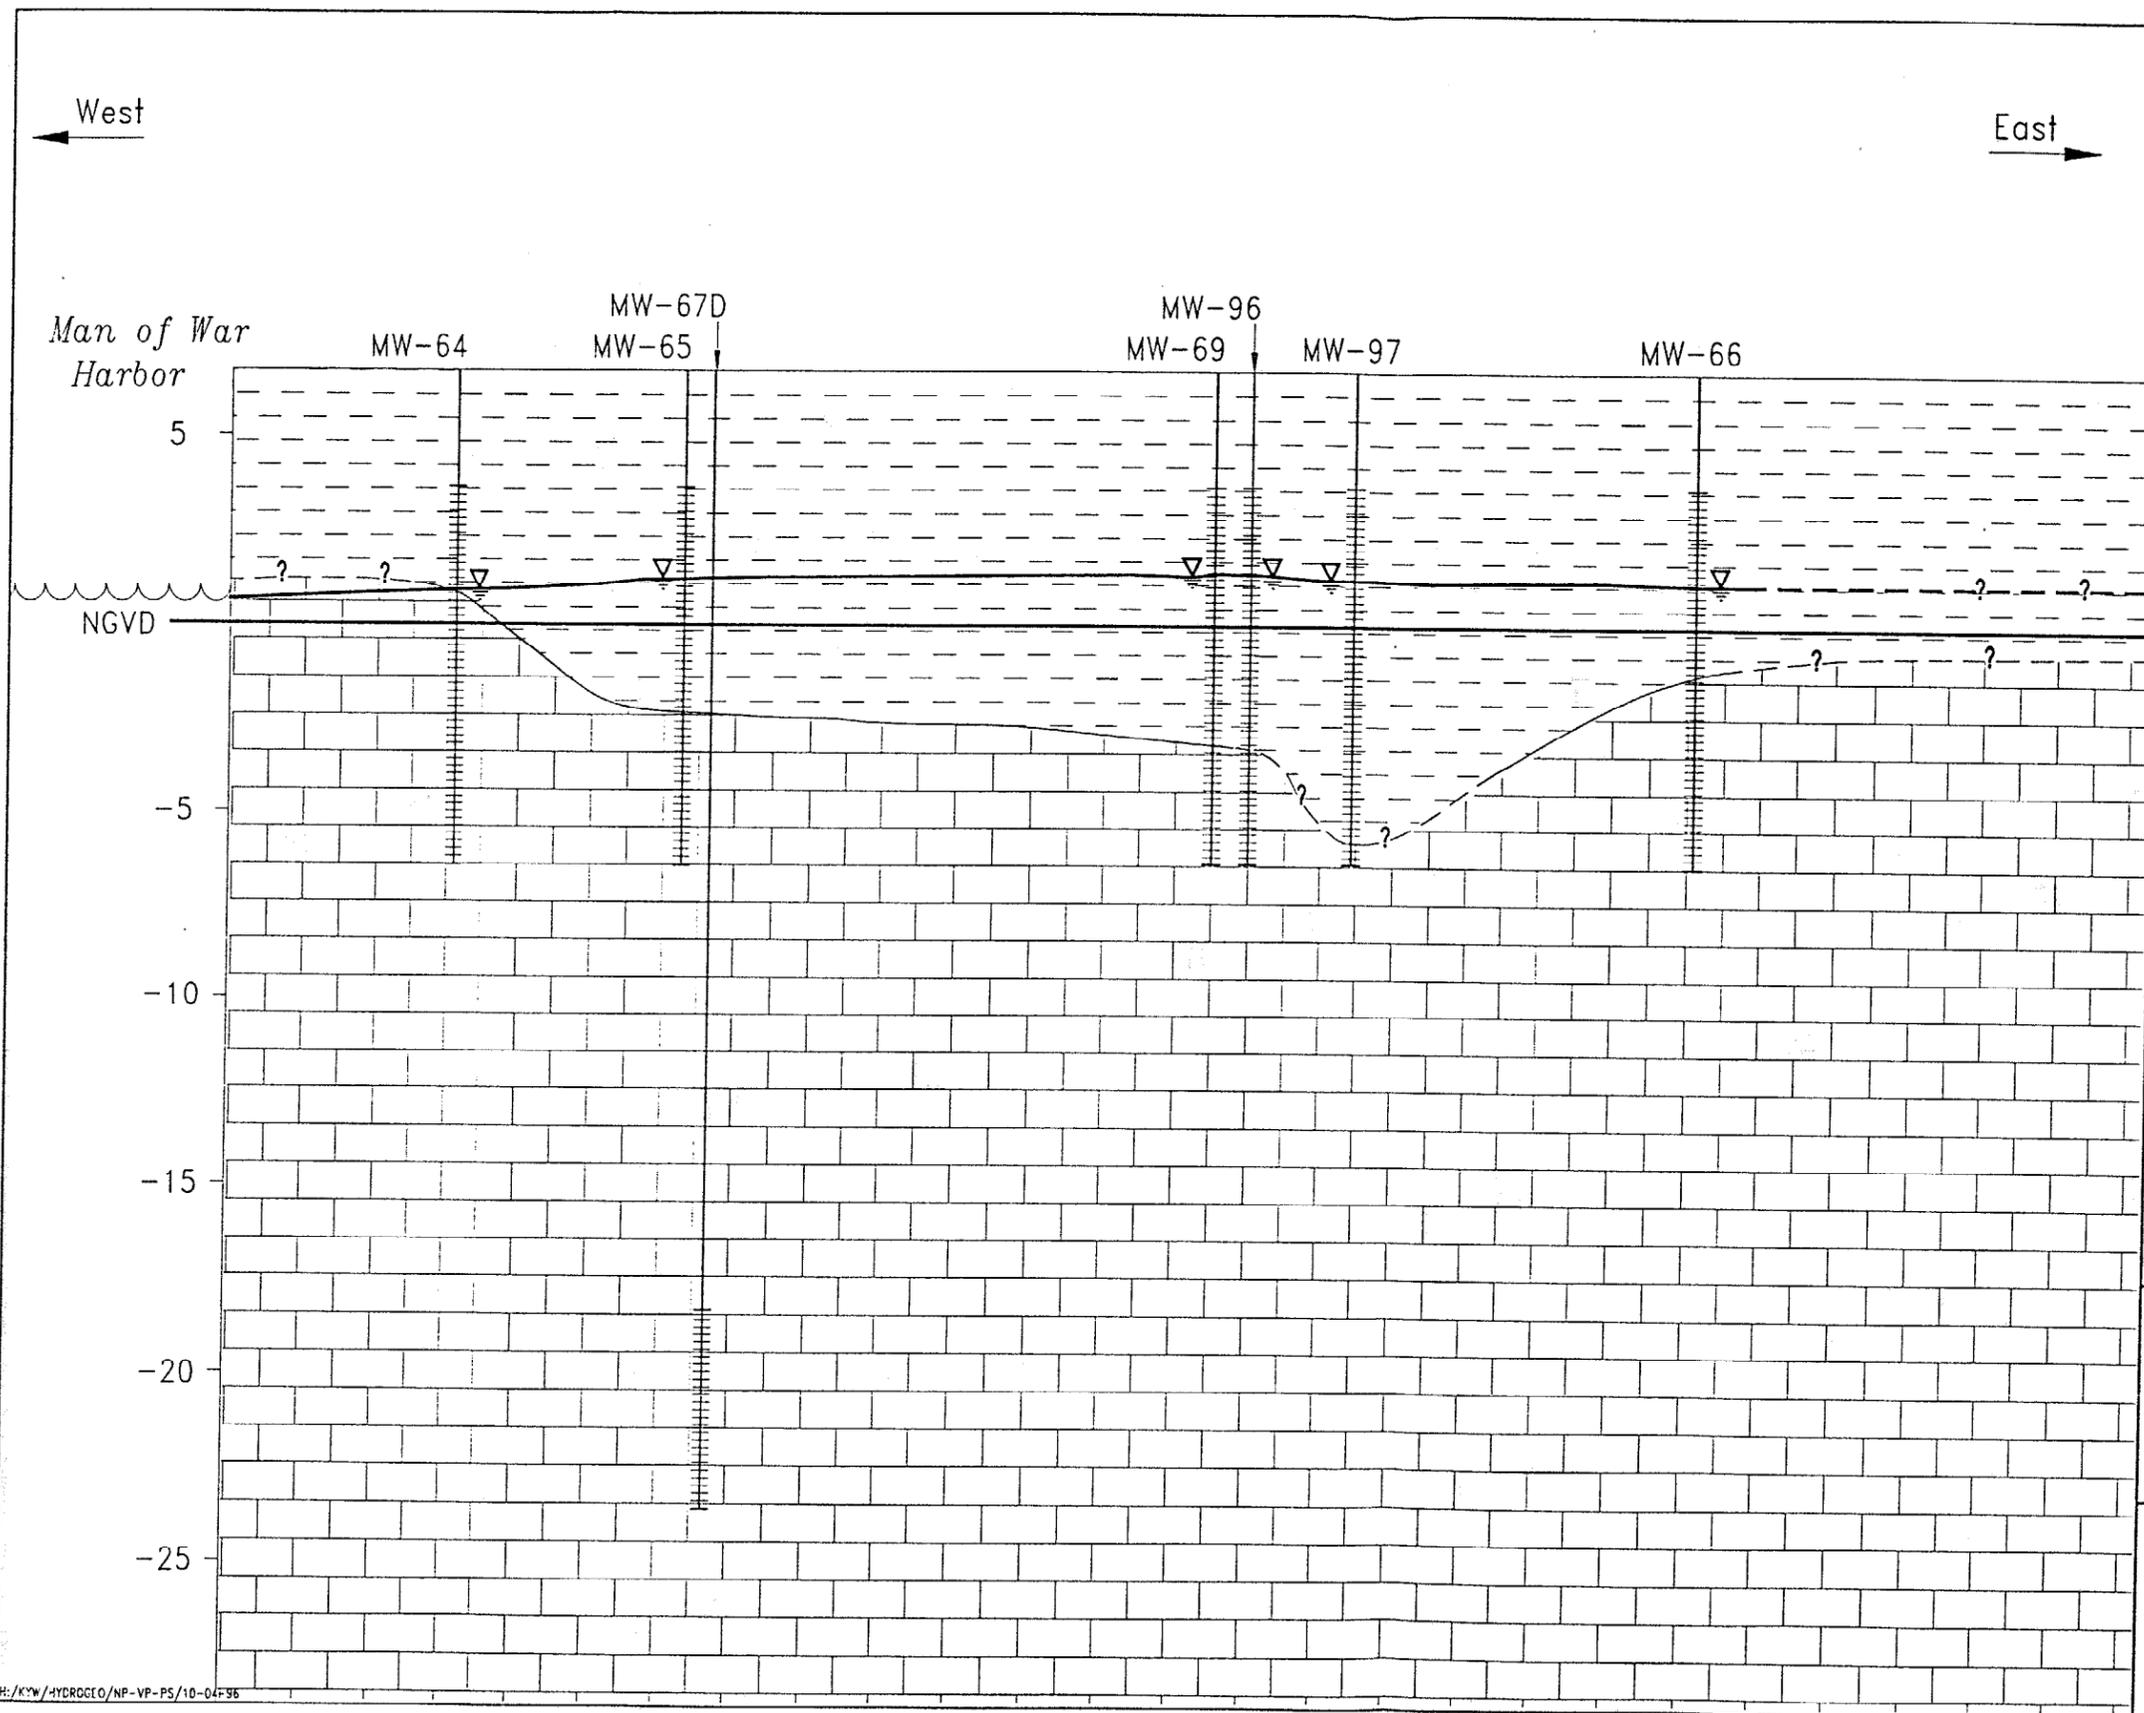

Groundwater at the site is encountered approximately 4 to 5 feet bls. Because of the high hydraulic conductivity of the limestone, groundwater elevations in site monitoring wells screened in the oolitic zone of the surficial aquifer are expected to be significantly influenced by tidal fluctuations. On the other hand, low permeability in the fill material and the seawall on the north side of the site are expected to attenuate tidal influences on the water table in the upper 10 feet of the shallow aquifer.

5.7.3 Tidal Study Methodologies A tidal influence study was conducted at the USCG facility beginning 16:06 on March 15th, and ending 08:30 on March 17th, 1996. The tidal influence study was conducted between the last quarter and the new Moon when tidal fluctuations are near maximum levels. Water levels were monitored for approximately 39 hours at 15-minute intervals using a data logger and pressure transducers. Pressure transducers were placed in five shallow and two deep monitoring wells and in the harbor adjacent to Pier D-3 to monitor tidal fluctuations in open water for comparison with water levels recorded in the monitoring wells. The top-of-casing elevation at each monitoring station was surveyed and referenced to a benchmark at the site.

Shallow monitoring wells are screened across the water table predominantly in the clayey calcareous fill material, which ranges from approximately 5 feet to 10 feet in thickness. The shallow wells have 10-foot screen intervals that penetrate approximately 2 to 3 feet into the oolitic limestone below the clayey fill. Deep monitoring wells at the site are screened in the oolitic limestone. Deep monitoring wells MW-67D and MW-48D extend to a total depth of 30 feet bls with a 5-foot screen interval from 25 to 30 feet bls. A hydrogeological cross section of the tidal influence study area showing site lithology, well locations, screen intervals, and water table elevations are presented on Figure 5-9.

5.7.4 Tidal Influence Study Results Water-level data recorded in the harbor during the tidal influence study (Table 5-8) indicate the tidal cycle at the site is semi-diurnal (two high tides and two low tides of similar magnitude in a 24-hour period). Water-level elevations plotted at 15-minute time intervals show deep monitoring wells MW-67D and MW-48D which are screened in the oolitic limestone were significantly affected by tides (Figure 5-10). Water levels in deep monitoring well MW-67D fluctuated approximately 1.5 feet, exceeding those in the harbor (0.9 foot) and in MW-48D (0.6 foot). Water-level fluctuations in the deep wells showed a time lag with tidal fluctuations in the harbor ranging from 0 to 30 minutes.

Water-level elevation and elapsed time data in shallow wells MW-37, MW-64, MW-65, MW-68, and MW-69 show tidal influence is minimal in monitoring wells MW-65, MW-68, and MW-69, and significantly attenuated in monitoring well MW-37 (Figure 5-11). MW-64 water-level elevation data, however, show significant water-level fluctuations corresponding to the first flood tide and second ebb tide of the semi-diurnal cycle. The water level in well MW-64 rose during the first flood tide (0 to 165 minutes elapsed time), but did not fall as the tide ebbed (195 to 570 minutes elapsed time, Figure 5-11 and Table 5-8). The groundwater elevation remained high during the second flood tide (570 to 975 minutes elapsed time) then began to fall 60 to 90 minutes before the second ebb tide. This phenomenon was repeated during the next tidal cycle.

The reason shallow monitoring well MW-64 is so strongly influenced by tidal fluctuations appears to be because most of the well screen (approximately 70 percent) is in the limestone. Lithologic logs indicate shallow well MW-64 penetrates approximately 7 feet into the oolitic limestone below the clayey fill material, which is less than 6 feet thick in this area.

Shallow monitoring well water-level elevation data indicate that a reversal in groundwater flow direction may occur at the site in the vicinity of well MW-64. The groundwater flow direction at the water table, which is generally westward toward the harbor, is shown by the elevation data on Figure 5-11. Monitoring wells farther inland have higher water-level elevations than wells closer to the harbor. However, during approximately 12.5 to 13.5 hours of the tidal cycle (180 to 915 minutes and 135 to 945 minutes elapsed time), the water-level elevation was higher in MW-64 than in MW-65 and MW-68, which are farther inland. Water-level fluctuations in well MW-37 are significantly less than those in well MW-64 and, apparently, are not large enough to cause reversals in groundwater flow direction near well MW-37.

5.8 PUMPING TEST.

5.8.1 Purpose and Scope Constant-rate pumping tests at the USCG facility were conducted on March 19th and 20th, and April 11th and 12th, 1996, to estimate hydraulic characteristics of the upper and lower zones of the surficial aquifer. The purpose of the pumping tests was to support the design of a groundwater treatment system. This section presents the data collected during the pumping tests, and discusses the hydraulic characteristics used to calculate the capture zone for the recovery well(s) that may be proposed as part of a groundwater treatment system.

5.8.2 Background The aquifer characterization pumping tests were conducted on the north side of the Coast Guard station, south of Fleming Key Cut and east of Pier D-3 using monitoring wells MW-37, MW-48D, MW-64, MW-65, MW-66, MW-67D, MW-68, MW-69, MW-96, and MW-97. The surface area in the vicinity of the pumping test wells primarily consists of asphalt pavement and grass. The seawall north of the site is constructed of concrete and extends to a depth of approximately 40 feet bls. Locations of pumping well MW-69 and adjacent observation wells MW-96, MW-97, and MW-66 are shown on Figure 4-2.

5.8.3 Pumping-Test Methodologies Beginning at 20:30 on March 19, 1996, deep monitoring well MW-67D was pumped at a constant rate of 5 gpm for 540 minutes. Water levels in pumping well MW-67D and six nearby monitoring wells (MW-65, MW-64, MW-68, MW-37, MW-48D, and MW-69) were recorded using pressure transducers and a data logger for the duration of the pumping test. Water levels in the harbor at the southeast corner of Pier D-3 were also monitored to record open-water tidal fluctuations. The water level in MW-67D was approximately 6.0 feet bls at the start of the pumping test.

Beginning at 08:01 on April 11, 1994, shallow monitoring well MW-69 was pumped at a constant rate of 0.87 gpm for 1,000 minutes. Water levels in pumping well MW-69 and three adjacent monitoring wells (MW-96, MW-97, and MW-66) were recorded using pressure transducers and a data logger for the duration of the pumping

test. Water-level monitoring in all four wells continued for 860 minutes after the pump was shut off. The water level in MW-69 was approximately 4.6 feet bls at the start of the pumping test.

5.8.4 Deep Monitoring Well Pumping-Test Results Water-level measurements in deep and shallow observation wells in the vicinity of pumping well MW-67D indicate that observation wells were unaffected by pumping during the deep well pumping test. The water level in shallow observation well MW-65, located 7 feet west of pumping well MW-67D, fluctuated less than 0.04 foot during the pumping test and showed little or no response to tidal fluctuations. Water-level fluctuations in shallow observation wells MW-37 and MW-64, and deep observation well MW-48D, appear to be related solely to tidal influence. Deep monitoring well MW-67D was pumped approximately 9 hours at a measured discharge rate of approximately 5 gpm.

5.8.5 Shallow Monitoring Well Pumping-Test Results Groundwater elevation measurements from the two observation wells and one pumped well were plotted and analyzed to calculate transmissivity and storage coefficient values for the clayey fill material. Water-level data collected at wells MW-69, MW-96, and MW-97 show a substantial difference in the magnitude of drawdown measured in the recovery well and the drawdowns measured in the monitoring wells. Pumping test results are presented graphically as log-log plots of time versus drawdown and time versus displacement in Appendix G.

5.9 AQUIFER CHARACTERIZATION.

5.9.1 Deep Well Type-Curve Analysis Type curves for an unconfined aquifer developed by S.P. Neuman and M.S. Hantush were fitted to the data using AQTESOLV (Geraghty & Miller, 1989). Log-log plots of drawdown versus time data for pumping well MW-67D are shown in Appendix G (Figures G-1 and G-2).

Drawdown data from pumping well MW-67D did not fit well with the type curves; however, best-fit curves were used to obtain a rough estimate of aquifer parameters. Factors that may have contributed to the deviation from typical time-drawdown response curves in the well include lithological variations between the limestone and overlying fill material, well inefficiency, and variations in permeability or porosity within the oolitic limestone.

Values for transmissivity (T), storativity (S), and specific yield (s_y) were obtained by matching the data with the Neuman type curve using a compressibility factor (β) of 0.001 for water in the aquifer. The Neuman type-curve solution assumes a partially penetrating well in an unconfined aquifer and the Hantush curve assumes there is a confining layer with leakage occurring. Estimated values of T for all of the solutions was approximately 50 square feet per day (ft^2/d). The estimated value for both S and s_y was 1.5×10^{-3} . The calculated T value gave a reasonable hydraulic conductivity (K) value for porous limestone of 1.63 feet per day (ft/d) or 12.2 gallons per day per foot ($\text{g}/\text{d}/\text{ft}$). Typical K values for limestone range from 10^{-2} to 10 $\text{g}/\text{d}/\text{ft}$ (Freeze and Cherry, 1979).

Well-recovery data was not collected in the pumping well because the pump failed and shut down during the night when the equipment was unattended.

5.9.2 Shallow Well Type-Curve Analysis Type curves for an unconfined aquifer developed by S.P. Neuman (1975) were fitted to the data using AQTESOLV (Geraghty & Miller, 1989). Log-log plots of drawdown data for observation wells MW-96 and MW-97 throughout the duration of pumping are shown in Appendix G (Figures G-3 and G-4).

Drawdown data from pumping well MW-69 were not fitted to type curves because lithologic variations in the screened interval are not representative of the clayey fill material. MW-69 is screened approximately 3 feet into the limestone, which is much more transmissive than the overlying fill material. Water from the underlying limestone, therefore, flowed to the pumping well at a higher rate than water in the fill material, giving the aquifer the appearance of having higher values for the estimated aquifer parameters.

Values for T, S, and s_y were obtained by matching the data with the type curves using a β of 0.001 for water in the aquifer. Estimated values of T range from 174.2 ft²/d in MW-96 to 334.7 ft²/day in MW-97 for an average value of 254.5 ft²/d. Values for S range from 0.007 to 0.013 for an average of 0.010. Values for s_y range from 0.006 to 0.011 for an average of 0.009. Using the value of T estimated from the pumping test data, however, did not give reasonable K values for the clayey fill material. Typical K values for clay deposited in a marine environment range from 10⁻⁵ to 10⁻² g/d/ft (Freeze and Cherry, 1979).

Well-recovery data, however, give a much more reasonable value for hydraulic conductivity than do the pumping test data. Recovery data from well MW-69 were entered into the AQTESOLV program using the formula developed by Bouwer and Rice (1976) for estimating K in unconfined aquifers with completely or partially penetrating wells. A log-log, time versus displacement plot of the recovery data in pumping well MW-69 is shown in Appendix G (Figure G-5). The calculated value of K using the Bouwer and Rice method was 2.0x10⁻⁵ feet per minute or 2.15x10⁻¹ g/d/ft. Inserting this K value into the equation:

$$T = Kb \tag{1}$$

where:

b = aquifer thickness (10 feet); then,
T = (0.215 g/d/ft) (10 feet); or,
T = 2.15 g/d

5.10 HYDRAULIC GRADIENT AND GROUNDWATER FLOW VELOCITY. The hydraulic gradient and groundwater flow direction were assessed in both the shallow water table zone and deep zone using groundwater elevations in site monitoring wells. Shallow monitoring wells have screen intervals typically from 3 feet to 13 feet bls. Deep monitoring wells are screened from 25 feet to 30 feet bls. The hydraulic gradient was calculated using the following equation:

$$i=h/d \quad (2)$$

where:

- i = hydraulic gradient (feet per foot [ft/ft])
- h = hydraulic head difference between two monitoring points parallel with groundwater flow direction
- d = distance between gradient monitoring points (feet)

5.10.1 Shallow Zone Hydraulic Gradient Groundwater levels measured on April 16, 1996, were used to calculate a range for the hydraulic gradient of the water table at the site. The hydraulic gradient in the shallow zone is lowest in the southwest area of the fuel farm between Tank D-3 and Building B-48. Therefore, using the equation:

$$i=h/d \quad (3)$$

where:

- h = 0.19 foot hydraulic head difference between monitoring points MW-40 and MW-7 (1.59 feet minus 1.40 feet)
- d = 225 feet
- i = 0.19 foot / 225 feet

$$i = 8.0 \times 10^{-4} \text{ ft/ft}$$

The greatest shallow zone hydraulic gradient is in the north central area of the fuel farm approximately 100 feet east of Tank D-1. Therefore, using equation (3),

- h = 0.89 foot hydraulic head difference between monitoring points MW-54 and MW-56 (1.78 feet minus 0.89 foot)
- d = 90 feet
- i = 0.89 foot / 90 feet

$$i = 1.0 \times 10^{-2} \text{ ft/ft}$$

5.10.2 Deep Zone Hydraulic Gradient The hydraulic gradient in the deep zone over most of the site is approximately 1.0×10^{-3} ft/ft.

The hydraulic gradient in the deep zone is lowest in the north central area of the USCG facility north of the basketball court. Therefore using equation (3),

- h = 0.04 foot hydraulic head difference between monitoring points MW-67D and MW-48D (1.26 feet minus 1.22 feet)
- d = 160 feet
- i = 0.04 foot / 160 feet

$$i = 2.5 \times 10^{-4} \text{ ft/ft}$$

5.10.3 Shallow Zone Groundwater Flow Velocity By calculating the hydraulic conductivity, hydraulic gradient, and effective porosity, the average pore water velocity (ν) can be estimated from the relationship:

$$\nu = Kxi/n_e \quad (4)$$

where:

ν = average linear pore water velocity in ft/day,
K = hydraulic conductivity in ft/day,
i = hydraulic gradient in ft/ft, and
 n_e = effective porosity in percent.

The shallow zone K value calculated from pumping test well recovery data equals 2.15×10^{-1} g/d/ft or 2.88×10^{-2} ft/day.

The predominant lithology of the shallow water table aquifer is fill material consisting primarily of calcareous mud (clay- and silt-size particles); therefore, an effective porosity of 45 percent or 0.45 was estimated for the shallow aquifer (Freeze and Cherry, 1979).

K = 2.88×10^{-2} ft/d
i = 8.0×10^{-4} ft/ft (smallest gradient)
i = 1.0×10^{-2} ft/ft (largest gradient)
 n_e = 0.45

Substituting these parameters into equation (4) gives a range of ν from 5.12×10^{-5} ft/d to 6.4×10^{-4} ft/d.

5.10.4 Deep Zone Groundwater Flow Velocity The deep zone hydraulic conductivity value calculated from pumping test well recovery data equals 12.2 g/d/ft or 1.63 ft/d.

The predominant lithology of the deep zone of water table aquifer is oolitic limestone; therefore, an effective porosity of 20 percent or 0.20 was estimated for the shallow aquifer (Freeze and Cherry, 1979).

K = 1.63 ft/d
i = 2.5×10^{-4} ft/ft (smallest gradient)
i = 1.0×10^{-3} ft/ft (largest gradient)
 n_e = 0.20

Substituting these parameters into equation (4) gives a range of ν from 2.04×10^{-3} ft/d to 8.15×10^{-3} ft/d.

5.11 AQUIFER TEST CONCLUSIONS. Hydraulic conductivity data were calculated for the clayey fill material and underlying limestone aquifer using shallow pumping well recovery data and transmissivity values from type-curve analysis of deep well pumping data. Water-level elevation data were used to calculate hydraulic gradients in the shallow and deep zones of the water table. Hydraulic conductivity and water-level elevation data were used to calculate groundwater flow

velocity in both the shallow and deep zones of the water table aquifer. The results illustrate substantial differences between the clayey fill material and the underlying limestone of the oolitic Miami Limestone.

Plots of the corrected drawdown data from shallow observation wells MW-96 and MW-97 are uncharacteristic of an aquifer with radial flow to a pumped well. The drawdown data indicates the existence of a zone of higher hydraulic conductivity. Flow into the shallow wells from the underlying oolitic limestone is believed to be the explanation for the high transmissivity values calculated from the pumping test data.

The aquifer parameters calculated in this section represent estimates. The numbers provide a conceptual picture for the local aquifer conditions at the TPF and USCG site, but should not be viewed as precise values.

6.0 SUMMARY, CONCLUSIONS, AND RECOMMENDATIONS

6.1 SUMMARY. Based on the findings of the CA field investigations and laboratory analytical results, the following is a summary of existing conditions at the site.

Aquifer Characteristics and Hydrogeologic Parameters Summary.

- The sediments encountered during drilling operations are generally composed of silty clay, oolitic lime mud, and oolitic limestone.
- Groundwater beneath the site was encountered at depths of approximately 4 to 6 feet bls and is classified as G-III.
- The direction of groundwater flow in the surficial zone has consistently been radially away from the TPF and toward the northwest on the piers.
- The average hydraulic gradient in the shallow zone at the site ranges from 8×10^{-4} to 1×10^{-2} ft/ft.
- The average hydraulic gradient in the deep zone at the site ranges from 2.5×10^{-4} to 1×10^{-3} ft/ft.
- The hydraulic conductivity in the shallow zone at the site is 2.88×10^{-2} ft/d.
- The hydraulic conductivity in the deep zone at the site is 1.63 ft/d.
- The shallow zone pore water velocity ranges from 5.12×10^{-5} to 6.4×10^{-4} ft/d.
- The deep zone pore water velocity ranges from 2.04×10^{-3} to 8.15×10^{-3} ft/d.

Soil CA Summary.

- Five areas of excessively contaminated soil were identified by OVA headspace analyses. The largest areal extent of soil contamination is located immediately north of the JP-5 tanks. Other areas of excessively contaminated soil included Pier D-2 in the vicinity of Building 105, the area around the basketball court and softball field, the west end of Pier D-1, and the east end of Pier D-1 (see Figure 5-1).
- Four areas of excessively contaminated soil were identified by laboratory analysis. TRPH concentrations in soil exceed the Chapter 62-770, FAC, target level of 50 ppm in the former tank D-5 area, the area around tank D-21, the area of the oil-water separator, and the area of the oily-waste water pump station on Pier D-1.
- The sediment sample analytical data collected from the surface water bodies adjacent to the site indicate no detections above the detection limit for VOCs and EDB, however, elevated concentrations of PAH, TRPH,

and lead were detected in some or all of the samples. The source of contamination in surface water sediment may be attributed to past oil seepage, bilge water discharges, and particles of lead-based paint from naval vessels operating at the facility.

Groundwater CA Summary.

- Two areas of total VOA contamination in groundwater were identified during the CA. One large area is in the northeast part of the fuel farm in the vicinity of the JP-5 tanks. The highest total VOA concentrations in this area were observed in MW-4 (1,193 ppb) and MW-60 (670 ppb), which exceeded the 50 ppb State target level. The second smaller area is on the north side of Pier D-1 in the vicinity of the oily-wastewater pipelines. Total VOA concentrations observed in MW-15 (87.2 ppb) exceeded the 50 ppb State target level (see Figure 5-2).
- The benzene contamination plume overlaps the area of total VOA contamination and is generally in the same location. The area of benzene contamination includes the former AVGAS AST area occupied by tanks D-15 through D-18 and the associated pipelines (see Figure 5-2). The highest benzene concentrations were in the groundwater samples collected from MW-4 (990 ppb) and MW-60 (620 ppb). This area of benzene contamination greatly exceeded the Chapter 62-770, FAC, target level of 1 ppb.
- Total naphthalenes concentrations exceeded the Chapter 62-770, FAC, Class G-II groundwater target level of 100 ppb in the samples collected from monitoring wells MW-15 (174 ppb), MW-50 (196 ppb), and MW-55 (1,750 ppb). MW-15 is located on the north side of Pier D-1, MW-50 is located north of Building D-19 and MW-55 is located north of the JP-5 tank #1 (see Figure 5-3).
- Three areas of TRPH contamination in groundwater exceeding the Chapter 62-770, FAC, target level of 5 ppm were identified (see Figure 5-4). These areas are associated with samples collected from monitoring wells MW-55 (157 ppm), KWM-01 (15.7 ppm) and MW-86 (5.1 ppm).
- Lead concentrations in all monitoring well samples did not exceed the Chapter 62-770, FAC, target level of 50 ppb for Class G-II groundwater.
- Chlorinated compounds were detected in low concentrations in monitoring wells in isolated areas of the site.
- Free-floating petroleum product was observed in 18 site monitoring wells during the CA.
- No compounds were detected in any of the surface water samples collected except for toluene (1 ppb) in sample W003 and methylene chloride (3.9 ppb) in sample well. It is likely these compounds are attributed to activities associated with boats and ships docked at the site.
- No potable water sources were identified within a 0.25-mile radius of the site. Water is supplied via aqueduct from the mainland.

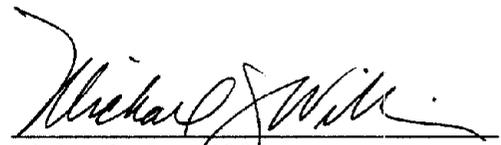

6.2 CONCLUSIONS. Based on the findings of the CA and site conditions, the following can be concluded:

- Excessive soil contamination in the area of the former AVGAS ASTs and associated piping is apparently related to leaks or releases from the ASTs and the fuel lines in the northern area of the TPF. Overall, soil contamination is limited to a 1- to 2-foot interval immediately above the water table.
- The areal extent of groundwater contamination exceeding Chapter 62-770, FAC, target levels is associated with the areas of excessively contaminated soil.
- The vertical extent of groundwater petroleum contamination appears to extend to greater than 30 feet of the surficial aquifer. Laboratory results reported contaminant concentrations in the groundwater samples collected from vertical extent well MW-74D (30 feet bls) exceeded Chapter 62-770, FAC, target levels for total VOAs both before and after a 3-day overdevelopment alternate procedure.
- The source of groundwater contamination is apparently due to previous releases from the associated AVGAS fuel pipelines in the vicinity of the ASTs, releases from pipeline junctions, a release from the oily-waste water line, and a release from the oily-waste water pump station.
- The sources of chlorinated compounds detected in site groundwater samples are suspected to be solvents and degreasing agents used at the site, and compounds used by the analytical laboratory during sample extraction. Chlorinated compounds do not appear to be a significant concern at the site.
- There are no potable water wells within a 0.25-mile radius of the site and drinking water is obtained via aqueduct from the mainland. The risk to human health caused by groundwater contamination is extremely low.
- There is no evidence to indicate that groundwater contaminants are migrating off the facility. Contamination is moving toward Fleming Key Cut, but does not appear to be a threat to surface water. For this reason, groundwater contamination at the site appears to be a low risk to area fish and wildlife.

6.3 RECOMMENDATIONS. Based on the findings, conclusions, and interpretations of the CA, ABB-ES recommends the continued implementation of an interim remedial action and the development of a remedial action plan (RAP). The primary contamination includes excessively contaminated soil, benzene, total VOAs, naphthalenes, and TRPH in groundwater. Free-product recovery efforts initiated at the site should be continued. An RAP will be developed to address the requirements of Chapter 62-770, FAC. One deep monitoring well, screened from 45 to 50 feet bls, should be installed adjacent to MW-74D during RAP preparation to delineate the vertical extent of groundwater contamination.

7.0 PROFESSIONAL REVIEW CERTIFICATION

This CAR was prepared under the direct supervision of a professional geologist registered in the State of Florida. The work and professional opinions rendered in this report were conducted or developed in accordance with commonly accepted procedures consistent with applicable standards of practice. This assessment is based on the geologic investigation and associated information detailed in the text and appended to this report referenced in public literature. Recommendations are based upon interpretations of the applicable regulatory requirements, guidelines, and relevant issues discussed with regulatory personnel during the site assessment. If conditions that differ from those described are determined to exist, the undersigned geologist should be notified to evaluate the effects of any additional information on this assessment or the recommendations made in this report. This report meets the criteria set forth in Chapter 492 of the Florida Statutes with regard to good professional practices as applied to Chapter 62-770, FAC. This CAR was developed for Trumbo Point Fuel Farm, NAS Key West, Key West, Florida, and should not be construed to apply to any other site.

1.0 INTRODUCTION

ABB Environmental Services, Inc. (ABB-ES), was contracted by Southern Division, Naval Facilities Engineering Command (SOUTHNAVFACENGCOM) to conduct a preliminary contamination assessment (PCA) and develop a Preliminary Contamination Assessment Report (PCAR) for the Trumbo Point Fuel Farm (TPFF) at Trumbo Point Annex, Naval Air Station (NAS) Key West, Florida. The scope of services for the work is described in Contract Task Order (CTO) No. 95, the Plan of Action (POA), and the Preliminary Contamination Assessment Plan (PCAP) for CTO No. 95.

1.1 PURPOSE. The purpose of the PCA was to assess the extent of petroleum contamination in soil and groundwater at the TPFF and recommend appropriate site investigations in accordance with Chapter 17-770, Florida Administrative Code (FAC), guidelines.

1.2 SCOPE. The scope of services developed to perform the PCA included:

- collection of soil samples and groundwater samples using a Geoprobe™ system,
- assessment of soil contamination by organic vapor analyzer (OVA) headspace techniques,
- installation of vertical extent monitoring wells to assess the vertical extent of groundwater contamination at the site,
- laboratory analyses of groundwater samples collected from Geoprobe™ borings and groundwater samples obtained from the vertical extent monitoring wells and previously installed monitoring wells, and
- reduction and analyses of all data gathered during the PCA to prepare a PCAR.

The following chapters of the report present the background information, data compilation, results, conclusions, and recommendations of the PCAR.

2.0 SITE DESCRIPTION AND HISTORY

NAS Key West, Monroe County, Florida, is located approximately 150 miles southwest of Miami. The TPF is located along the northern shore of Key West, south of Fleming Key Cut (Figure 2-1). The TPF is bordered on the north by Fleming Key Cut, on the west by a U.S. Coast Guard (USCG) facility, on the east by Mustin Street, and on the south by Whiting Avenue (Figure 2-2). Piers D-1, D-2, and D-3, located at the USCG facility, serve as a fuel depot for ships and aircraft.

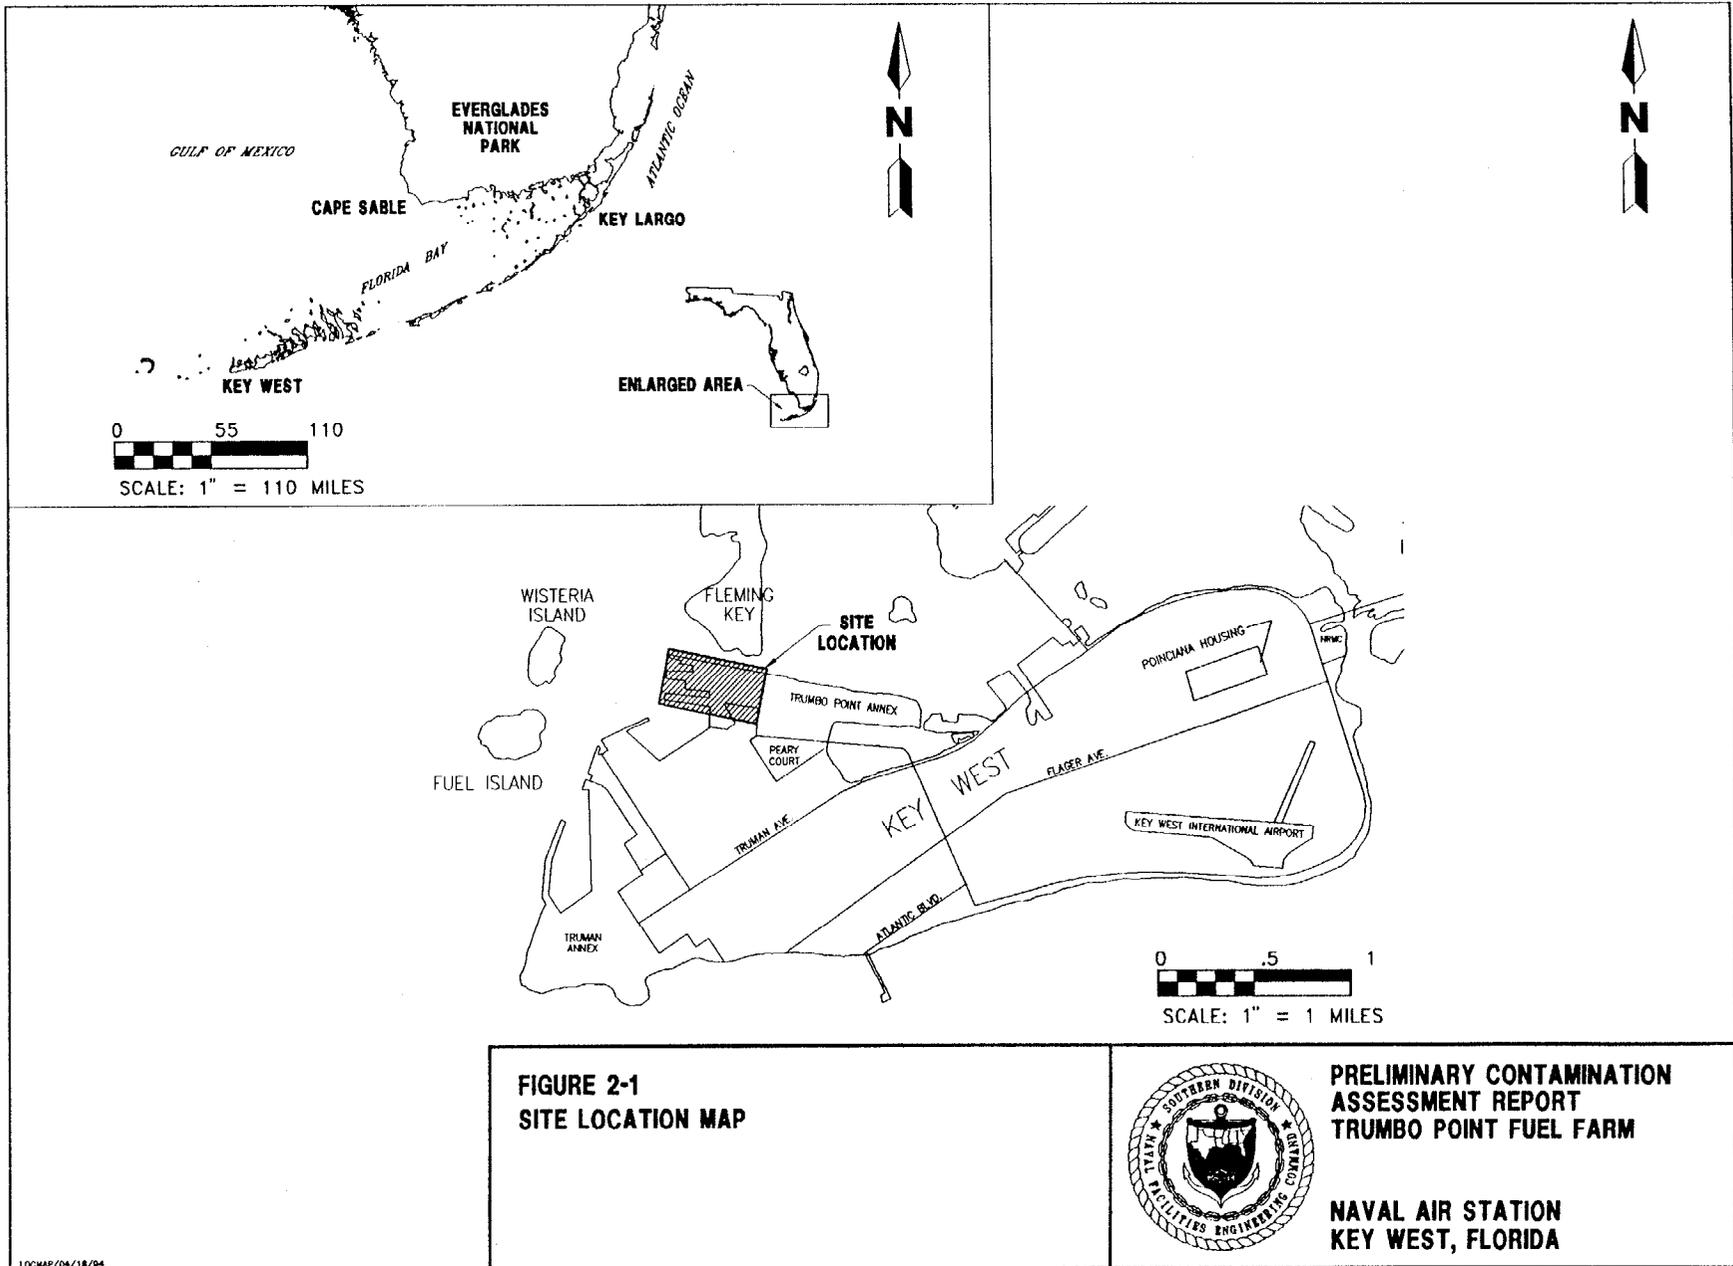

The TPF has been used as a fuel storage and distribution point since 1942 (Envirodyne Engineers, Inc., 1985). Fuels reported to have been stored and transported at the site include No. 6 fuel oil, Bunker C oil, diesel fuel, aviation gasoline (AVGAS), JP-4 and JP-5 jet fuels, motor gasoline (MOGAS), waste oil, and hydraulic fluids (Geraghty & Miller, 1987). According to Navy personnel, the TPF is currently used to store and dispense diesel fuel marine (DFM), JP-5 fuel, and MOGAS.

The TPF is the location of several aboveground storage tanks (ASTs), associated piping, and various pumphouses used to transport fuel from the ASTs (Figure 2-2). The site entrance is located along Trumbo Road near Building D-19. Building D-19 is used as an office and storage facility by site personnel. Buildings D-3A, D-15 through D-18, D-22 through D-25, D-26, and D-29 are pumphouses, which are now used or were formerly used to transport fuel from the site. The TPF is surrounded by an 8-foot high chain-link fence. A concrete seawall extends along the northern perimeter of the site. The seawall is approximately 1-foot thick and extends to a depth of approximately 15 to 20 feet below land surface (bls).

Parts of the USCG facility were investigated during this preliminary assessment. Details of features at the USCG facility will be discussed in later sections.

2.1 ABOVEGROUND STORAGE TANKS. There are eight active and two inactive ASTs at the TPF. AST volumes and construction details are presented in Table 2-1. Three JP-5 jet fuel tanks (tanks 1 through 3) are located in the north central and northeastern sections of the site. Tanks 1, 2, and 3 are operated by Key West Pipeline Company. Tanks D-1 through D-3, located along the western margin of the TPF, are maintained by Avantha, Inc., and are used to store DFM. A 20,000-gallon MOGAS AST is located west of DFM tank D-2 at the western edge of the TPF. A 1,000-gallon diesel AST is located on the east side of Building D-29 at the eastern edge of the TPF. Two inactive DFM ASTs, tanks D-4 and D-6, are located in the central and southern sections of the TPF, respectively.

Several ASTs, which formerly contained fuel, have been removed from the site. Eleven AVGAS tanks, installed in 1942 were abandoned in the late 1940's (Envirodyne Engineers, Inc., 1985). The locations of these former AVGAS tanks are not known. DFM ASTs D-5 and D-7, located in the southeast part of the site, were removed in 1985. Two 15,000-gallon MOGAS tanks located north of Building D-19 were removed in 1992 and replaced with the 20,000-gallon MOGAS tank currently in use.

¹ Contained JP-4 jet fuel prior to 1975.

² Converted to DFM storage by 1985.

³ Used for waste oil overflow from tank D-21 from 1982 to 1985.

⁴ Underground storage tank.

Notes: JP-5 = jet propellant 5 jet fuel.

JP-4 = jet propellant 4 jet fuel.

DFM = diesel fuel marine.

MOGAS = motor gasoline.

-- = not removed.

Historical areal photographs indicate there were three large ASTs at the site in 1930 (La Gorce, 1930). Two of the three ASTs were located at the USCG facility (Figure 2-2); one near the present location of the basketball court and the second at the present location of the softball field near Trumbo Road. The third AST was located between DFM tanks D-1 and D-2. The contents of the three ASTs are unknown. Areal photographs suggest that they may have been used for fuel storage to supply ships docked at Piers D-1 through D-3. The ASTs were reportedly removed sometime during the early 1960's.

2.2 UNDERGROUND STORAGE TANKS. A 1,050-gallon underground storage tank (UST), tank D-21, was located north of Building D-22 on the west side of the site (Figure 2-2). The UST was installed in 1942 and was used as a ballast sludge tank (Envirodyne Engineers, Inc., 1985). By the 1970's, the UST was used for the storage of waste oil and hydraulic fluid. Until the late 1970's, the waste oil was sold to contractors who hauled the material from the TPF. Subsequently, the waste oil was allowed to accumulate and, by 1982, the UST was full. Approximately 200 to 300 gallons of waste oil were transferred each month to tank D-5. Both tanks D-5 and D-21 were removed from the site around 1985. Four 20,000-gallon USTs (tanks D-15 through D-18) are located in the northeast corner of the TPF and are associated with Buildings D-15 through D-18. All four tanks are inactive. Tank D-18 was used to store waste Bunker C oil. The former contents of the other three tanks are unknown.

2.3 FUEL PIPELINES. Several aboveground and underground fuel pipelines are located at the site (Figure 2-2). DFM and JP-5 pipelines are used to transport fuel to and from Pier D-2 at the USCG facility. Aboveground JP-5 pipelines extend north from JP-5 tanks 1 through 3 and connect with an underground JP-5 pipeline, which continues west to the USCG facility. Within the USCG facility, the JP-5 pipeline is aboveground along the north side of Pier D-2 and along the south side of the softball field. An underground DFM pipeline connects DFM tanks D-1, D-2, and D-3 and extends west to Trumbo Road from DFM tank D-3. The DFM pipeline then continues north along the east side of Trumbo Road to the MORGAN AST. From that point the pipeline extends west to Pier D-2, parallel to the JP-5 pipeline.

Several unused fuel pipelines are present at the TPF site. An abandoned DFM pipeline extends from pumphouse D-26 near DFM tank D-4 to another abandoned DFM pipeline located along the west fence line of the site. An abandoned underground Bunker C oil pipeline reportedly existed along the western fence line of the TPF parallel to the abandoned DFM pipeline.

According to USCG facility personnel, three abandoned underground pipelines are located under the USCG facility access road south of the tennis courts. One pipeline was used to transport DFM and a second transported Bunker C oil. The contents of the third line are unknown. The pipelines continue west along the access road, then turn north near Building B-6 toward the slip north of Pier D-2.

2.4 SITE TOPOGRAPHY AND SURFACE FEATURES. The land surface at the site is relatively flat, except where 8-foot high, gravel berms separate the JP-5 ASTs in the northern part of the site. Earthen mounds surround tanks D-1 through D-4, and D-6; and several gravel roads in the south section of the TPF are graded

above the surrounding land surface. Except for the berms and mounds, ground elevations at the site vary from approximately 5 to 7 feet above mean sea level (msl). Most of the site is covered by grass, except paved areas in the vicinity of Building D-19 and the gravel roads and berms. Parking lots outside the southern edge of the TPFf near Building B-48 are covered with asphalt. Building B-48 activities are not related to activities at the TPFf.

There are three fire wells at or near the site. One fire well is located on the southwest side of DFM tank D-2, another is located near the northwest corner of Building C-48 on the west side of Mustin Street, and the third is located on the west side of Trumbo Road near the pumphouse at the USCG facility.

2.5 PREVIOUS FUEL RELEASES AND CONTAMINATION ASSESSMENTS. An initial assessment study indicated that two fuel releases occurred at the facility in 1981 (Envirodyne Engineers, Inc., 1985). In June 1981, there was a reported release of 5,000 to 6,000 gallons of DFM from a corroded pipeline located between tank D-4 and the D-26 pump house (Figure 2-3). All DFM was reportedly contained with no discharge to surface waters (Envirodyne Engineers, Inc., 1985). In October 1981, a pipeline leak on Pier D-2 at the USCG facility resulted in the discharge of 300 gallons of DFM into harbor waters. The spill was contained by boom and recovered (Envirodyne Engineers, Inc., 1985).

Contamination assessment investigations have been conducted at the TPFf since 1985, and several areas of concern were identified during these investigations (Figure 2-3). Geraghty & Miller (June 1985) conducted a subsurface hydrocarbon investigation during which 10 monitoring wells were installed at the TPFf. The Geraghty & Miller investigation confirmed the DFM contamination in the vicinity of tank D-4 reported by Envirodyne Engineers, Inc. (March 1985).

During a subsequent verification study (Geraghty & Miller, 1987), 15 soil borings were drilled and 6 additional monitoring wells were installed at the TPFf. Free product was detected in monitoring wells in the vicinity of JP-5 tanks 2 and 3, DFM tank D-4, and in the vicinity of Building D-23 located west of DFM tank D-3 and south of former waste oil tank D-21 (Figure 2-3). Dissolved petroleum constituents were detected in the vicinity of JP-5 tank 3. Additional site investigation and remedial action was recommended (Geraghty & Miller, 1987).

Another area of concern was identified along the northern boundary of the TPFf (Geraghty & Miller, 1988c). Geraghty & Miller personnel observed fuel seeping through openings in the seawall north of JP-5 tank 2 along the northern site boundary (Figure 2-3). The openings were sealed and a pit was excavated on the landward side of the seawall to recover free product. Several weeks later, fuel was again observed seeping through the seawall. The seawall was again sealed and another pit was excavated to recover the free product.

During an expanded site investigation (Geraghty & Miller, 1988b), free product detected in the vicinity of Building D-23, JP-5 tank 2, and DFM tank D-4 was confirmed. Free product was also detected in a monitoring well northwest of tank D-6. In addition, the September 1988 Geraghty & Miller investigation identified the following six other potentially contaminated areas at the site (Figure 2-3):

- the area north of DFM tank D-2 in the northwest section of the site, reportedly caused by overfilling tank D-2;

- the area between tank D-4 and former tank D-5 in the east-central section of the site, where oily wastewater was reportedly disposed;
- a waste oil drums storage area near an oil-water separator located south of Building D-24 on the western perimeter of the site;
- the former waste oil UST near Building D-23 located on the western perimeter of the site, where site personnel reported that the UST may have been used to store solvents, waste oil, pesticides, and polychlorinated biphenyls (PCBs);
- in two separate areas on Pier D-1 at the USCG facility suspected to result from releases of oily wastewater; and
- in the south central area of Pier D-3 at the USCG facility, where a release resulting from an underground petroleum pipeline is the reported source of contamination.

Geraghty & Miller (1988a) recommended further investigation at the TPF and Piers D-1 and D-3 and presented a workplan for an expanded site investigation and remedial field investigation.

A supplemental site investigation was conducted by International Technology Corporation (ITC). Forty-four soil borings and four monitoring wells were completed and sampled. Excessive soil contamination as defined in Chapter 17-770, FAC, was detected in the vicinity of DFM tanks D-1 through D-3, and JP-5 tanks 1 and 2. Excessive soil contamination as defined in Chapter 17-770, FAC, was detected along the southern boundary of Pier D-1 at two separate locations (see Figure 2-3). ITC (1991b) recommended that remedial action be implemented at the site. The recommended remedial action included treating excessively contaminated soil and sampling groundwater from existing monitoring wells.

During an initial site inspection in November 1992, ABB-ES observed several other areas of concern (Figure 2-3):

- free product observed in a fire well located between Building D-19 and tank D-2 in the western part of the TPF;
- the area surrounding JP-5 tank 1, located in the north central part of the TPF;
- the area surrounding JP-5 tank 3, located in the northeast section of the TPF;
- the area surrounding the inactive waste Bunker C tank (tank D-15) and tanks D-16 through D-18, located near JP-5 tank 3 in the northeastern section of the TPF;
- the area surrounding former tank D-5 located in the eastern section of the TPF; and
- the area surrounding former tank D-7 located in the southern part of the TPF.

2.6 REMEDIAL PILOT STUDY NEAR DIESEL FUEL MARINE (DFM) TANK D-4. A remedial pilot study was designed to test and evaluate a method for treating contaminated groundwater and recovering subsurface liquid-phase hydrocarbons east of tank D-4 (Geraghty & Miller, 1988a). The pilot study was implemented by ITC in 1990 and 1991. The remedial system consisted of an infiltration gallery with a center sump equipped with groundwater and free product pumps. Recovered free product was pumped into a 5,000-gallon product tank. Contaminated groundwater was treated by an air sparger system designed to treat groundwater at the rate of 50 gallons per minute (gpm). A leach bed was used for the disposal of treated groundwater.

The remedial system operated for 180 days. Because of the low horizontal permeability of soil, the actual groundwater yield was 1 gpm. Approximately 1,000 gallons of free product were recovered and 155,000 gallons of groundwater were treated. ITC (1991a) concluded that the recovery system used at the TFFF site was not a feasible remedial alternative because the low hydraulic conductivity of the soil limits the formation of a capture zone and inhibits groundwater recovery and the transport of free product. ITC (1991a) recommended extensive trenching to remove contaminated soil and to improve access to free product, and a site bioassessment and biotreatability study to evaluate the feasibility of bioremediation.

3.0 PRELIMINARY CONTAMINATION ASSESSMENT

Data from previous field investigations indicate significant soil and groundwater petroleum contamination at the TPF site. The horizontal and vertical extent of soil and groundwater contamination in many areas has not been adequately assessed. ABB-ES conducted a PCA to verify the findings of previous investigations and assess soil and groundwater contamination in areas not well documented during the previous investigations. The ABB-ES PCA was conducted from July through October 1993. At the request of the Navy, the area of investigation also included parts of the USCG facility, located west of the TPF site.

During the PCA, 101 soil borings were drilled and 3 vertical extent monitoring wells were installed. Soil samples were collected from soil borings and analyzed for volatile organic compounds (VOCs) by OVA analysis. Groundwater samples were collected from monitoring wells installed during previous investigations and from monitoring wells and specific soil borings completed during this investigation. Groundwater samples collected from soil borings were analyzed for total recoverable petroleum hydrocarbons (TRPH). Groundwater samples collected from monitoring wells were analyzed for constituents of the kerosene and mixed product analytical group as defined in Chapter 17-770, FAC. Methodologies and equipment used during the PCA are discussed in Appendix A, Methodologies and Equipment.

3.1 SITE-SPECIFIC HYDROGEOLOGY. Site-specific hydrogeologic characteristics were based on information obtained during soil boring and monitoring well installation and from previous investigations.

Subsurface material from land surface to a depth of approximately 3 feet bls is composed of hard, sandy limestone fill mixed with gravel and shell fragments (ITC, 1991a). Material from 3 feet bls to approximately 13 feet bls is generally a soft, silty to sandy limestone mud. A sandy to gravelly limestone occurs from 13 feet bls to 50 feet bls (the maximum depth of site monitoring wells). Site lithologies are graphically presented in soil boring logs for monitoring wells MW-1D through MW-3D. Soil boring logs are attached in Appendix B, Soil Boring Logs.

Grain size, permeability, pH, moisture, cation exchange capacity (CEC), and total organic carbon (TOC) analyses were performed for a composite soil sample collected from 0 to 4 feet bls near Trumbo Road, northwest of DFM tank D-3 (ITC, 1991b). Grain size analysis was representative of poorly sorted sand and gravel with an average particle diameter of 3 millimeters (mm). Particles ranged in size from cobble to clay. The permeability was 1.8×10^{-6} centimeters per second (cm/sec), with a uniformity coefficient of 1,025.00. TOC content was 4,900 milligrams per kilogram (mg/kg), moisture content was 39.2 percent, pH was 8.35, and CEC was 49.22 milliequivalents per gram (meq/g).

The water table was encountered at depths from 4 to 7 feet bls during this investigation. A tidal study performed during August 1990 indicates that water elevations are tidally influenced (ITC, 1991b). Sea level fluctuations ranged from 0.9 feet below msl to 1.4 feet above msl, and groundwater elevations ranged from 0.4 to 3.0 feet above msl. Groundwater elevations derived from water level measurements in three wells indicated a northwest flow direction at the TPF (ITC, 1991b). Measurements recorded during the investigation indicated no

consistent groundwater flow direction across the site, which suggests that tidal fluctuations are affecting groundwater flow direction.

3.2 SOIL ASSESSMENT. Soil borings SB-1 through SB-101 were drilled during the PCA. Soil borings SB-1 through SB-91 were drilled at the TPF, and soil borings SB-92 through SB-101 were drilled at the USCG facility. Soil boring locations and corresponding OVA headspace measurements are presented on Figure 3-1. The highest OVA readings from samples collected above the water table for each soil boring are shown on Figure 3-1. Results of the OVA headspace survey are presented in Appendix C, Soil Sample Organic Vapor Analyzer (OVA) Headspace Results.

Soil with an OVA headspace reading greater than 10 parts per million (ppm) is considered to be petroleum-contaminated; soil with an OVA headspace reading greater than 50 ppm is considered to be excessively contaminated (FDER, 1992). Excessively contaminated soil was found throughout the TPF and the USCG facility (Figure 3-1). The highest OVA readings (>2,500 ppm) were found in the vicinity of the three JP-5 tanks and DFM tank D-2.

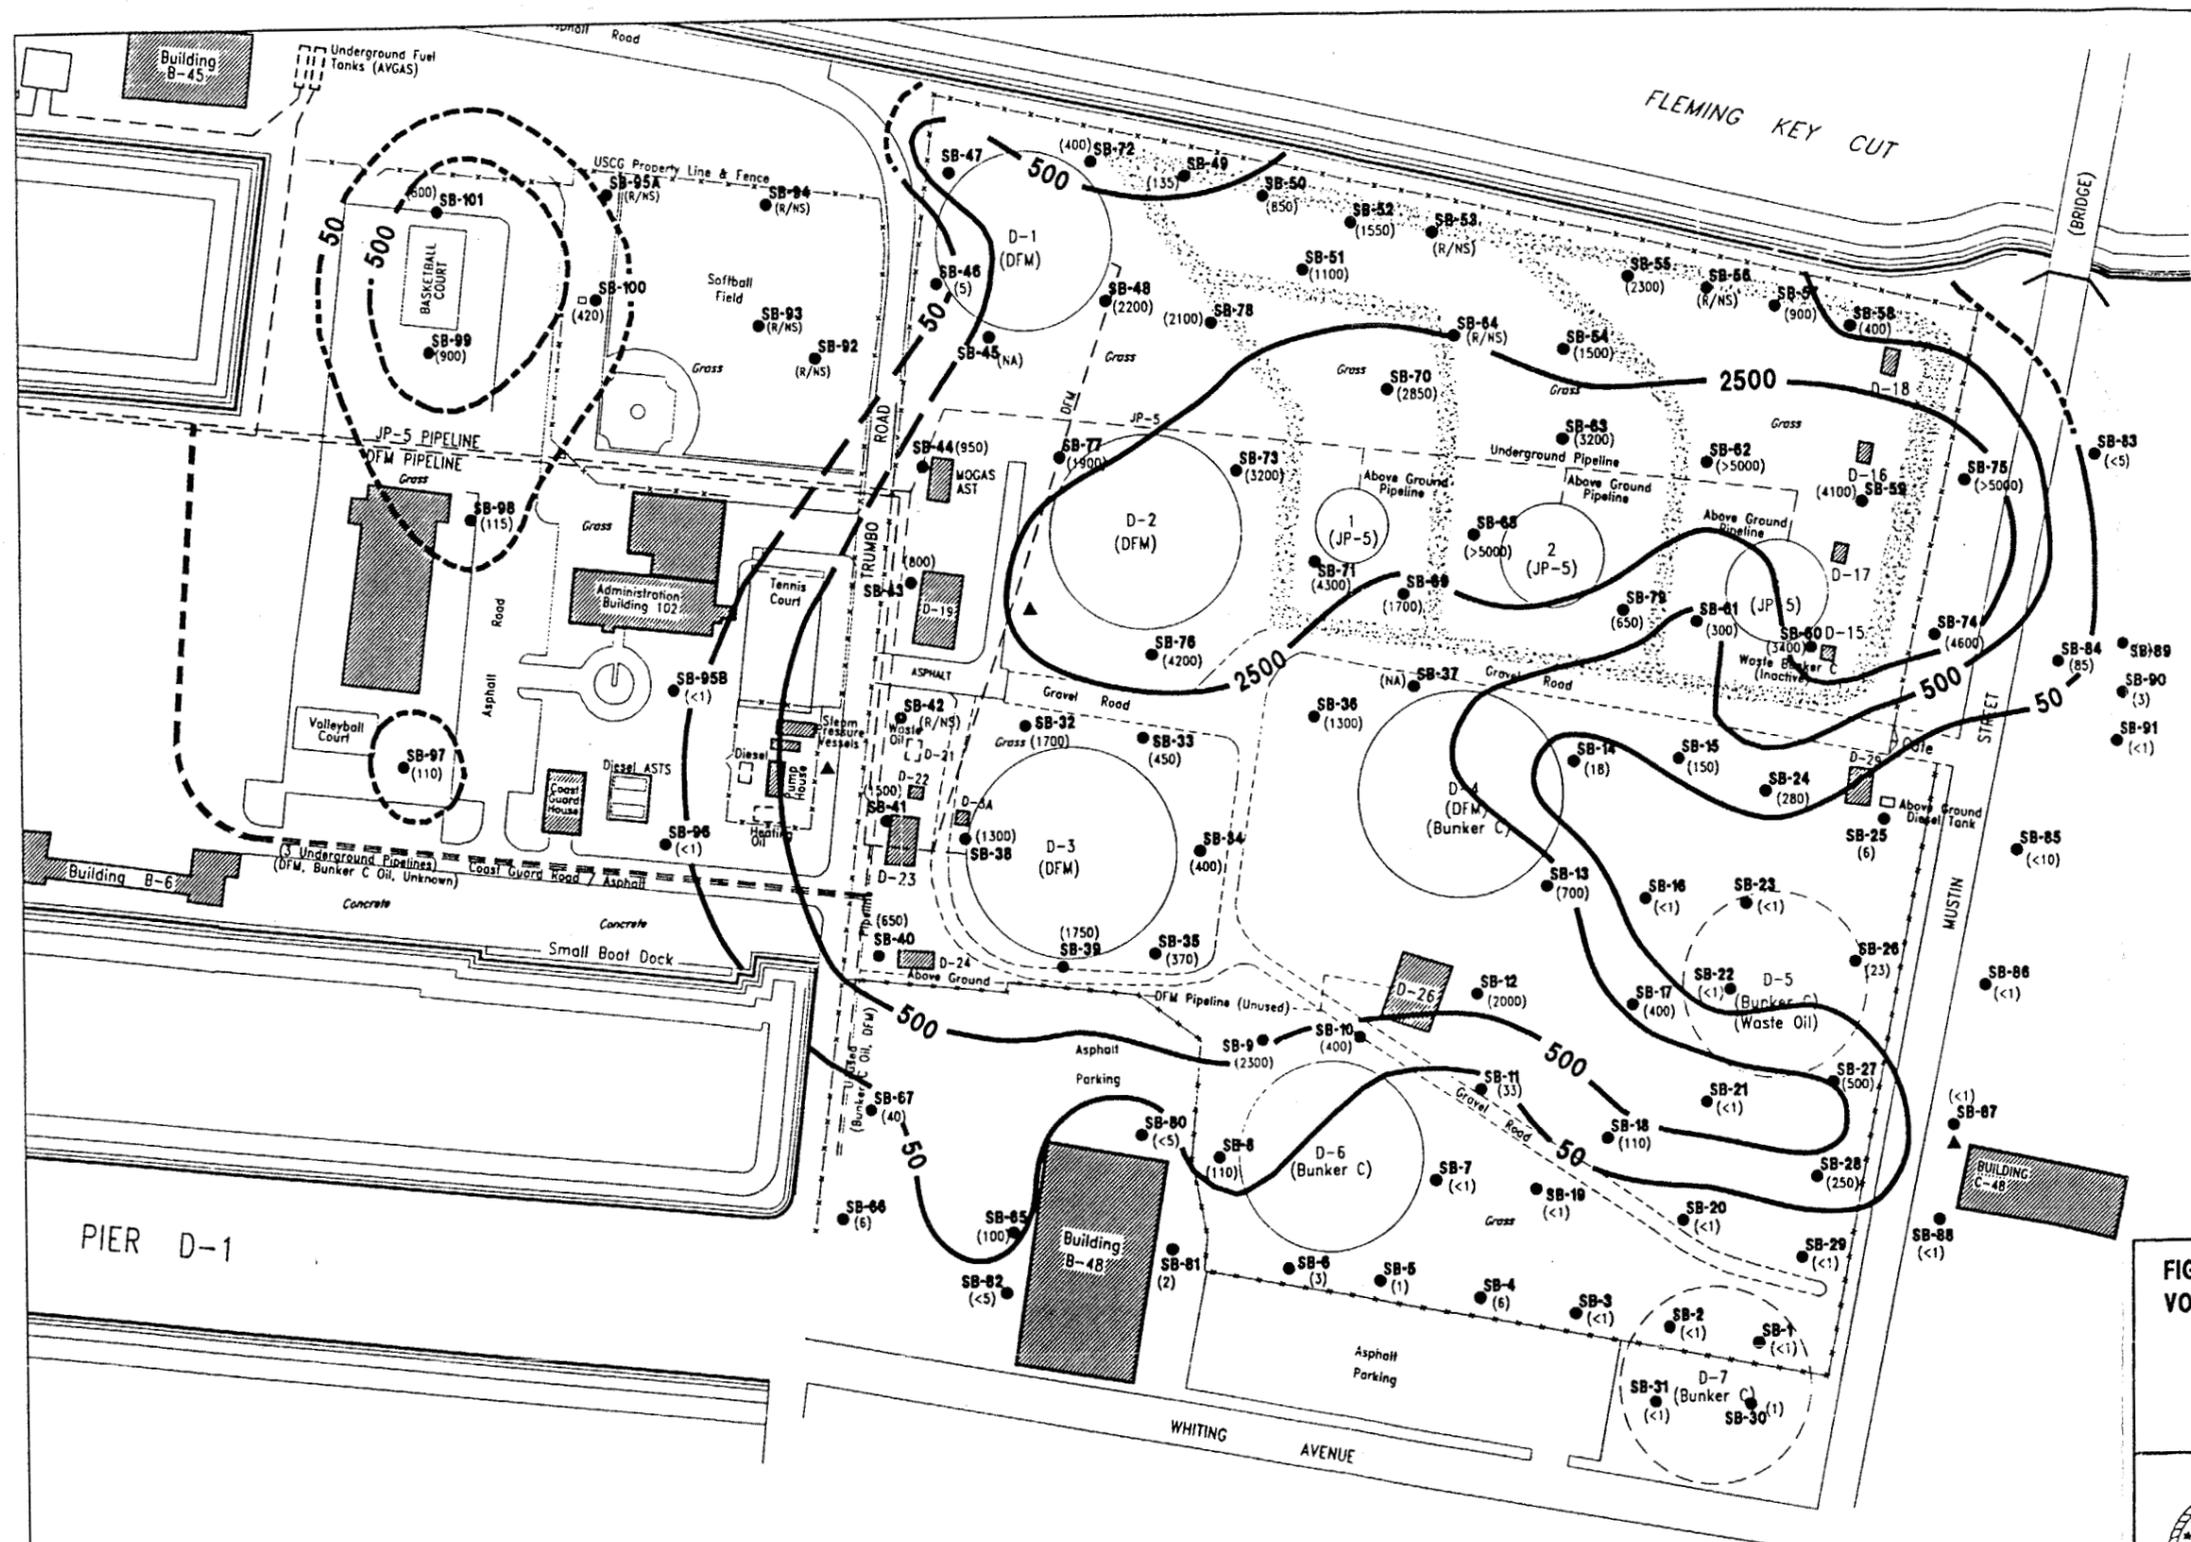

Based on the OVA data, the areal extent of soil contamination appears to be delineated along the eastern and southern boundaries of the TPF. Petroleum-contaminated soil does not appear to extend south of tank D-6 and Building B-48 along the southern boundary of the site. With the exception of soil boring SB-84, petroleum-contaminated soil was not identified on the east side of Mustin Street. Excessive soil contamination is present along the entire northern section of the TPF and was encountered over much of the western part of the site.

Excessively contaminated soil was also found at the USCG facility near the volleyball court and in the vicinity of the basketball court. Sufficient information is not currently available to determine the source(s) of soil contamination at the USCG facility; however, the low OVA headspace readings in soil borings SB-95 and SB-96, located southwest of the tennis courts, suggest that contamination near the volleyball court in soil boring SB-97 may be from a local source.

A soil sample was collected from soil boring SB-9, located near tank D-6, and analyzed for TRPH, arsenic, cadmium, chromium, and lead. Soil sample laboratory analyses are attached in Appendix D, Soil Analytical Data. The TRPH concentration was 3,600 ppm. Total metal concentrations were below detection limits.

3.2 GROUNDWATER ASSESSMENT. Monitoring well locations and soil borings from which groundwater samples were collected are shown on Figure 3-2. Monitoring wells KWM-01 through KWM-10, and KWM-20 through KWM-25 were installed during the Geraghty & Miller investigations conducted from 1985 to 1988. Monitoring wells MW9-10 through MW9-17 were installed by ITC from 1989 to 1991. Monitoring wells MW-1D through MW-3D are the vertical extent wells installed by ABB-ES during this investigation. Well construction information details are presented in Table 3-1.

No information was found concerning the installation history and construction details for monitoring well MW-JP-1, located near JP-5 tank 1.

 G&M = Geraghty & Miller, Inc.
 ITC = ITC Corporation.
 ABB-ES = ABB Environmental Services, Inc.
 -- = unknown.

Groundwater samples were collected from soil borings in July and August 1993. TRPH analyses were performed for samples collected from soil borings SB-1, SB-6, SB-7, SB-12, SB-25, SB-27, SB-32, SB-44, SB-52, SB-66, SB-72, SB-85, SB-95, SB-96, SB-97, SB-98, and SB-99. Duplicate analyses were performed for samples collected from soil borings SB-1, SB-32, and SB-97.

Groundwater samples were collected from monitoring wells MW-1D through MW-3D, KWM-08, KWM-09, KWM-20, KWM-21, KWM-24, KWM-25, MW9-11, and MW9-13 from August 31 through September 2, 1993. A duplicate sample was collected from monitoring well MW-3D. Monitoring wells KWM-01 and KWM-10 could not be located and apparently have been destroyed. Monitoring wells KWM-02 and KWM-05, located along Whiting Avenue south of the TPF, were not sampled because they are outside the contaminated area. The remaining monitoring wells were not sampled because they contained free product.

3.2.1 Free Product Contamination Free product was detected in monitoring wells KWM-07, KWM-22, KWM-23, MW9-10, MW9-12, MW9-13, MW9-15, MW9-17, MW-JP-1, and the fire well located southwest of DFM tank D-2. Viscous free product was also detected in SB-44 (located near the MOGAS AST), the underground JP-5 pipeline, and an abandoned Bunker C oil pipeline. Viscous free product was also detected in soil boring SB-101, located near the basketball court at the USCG facility.

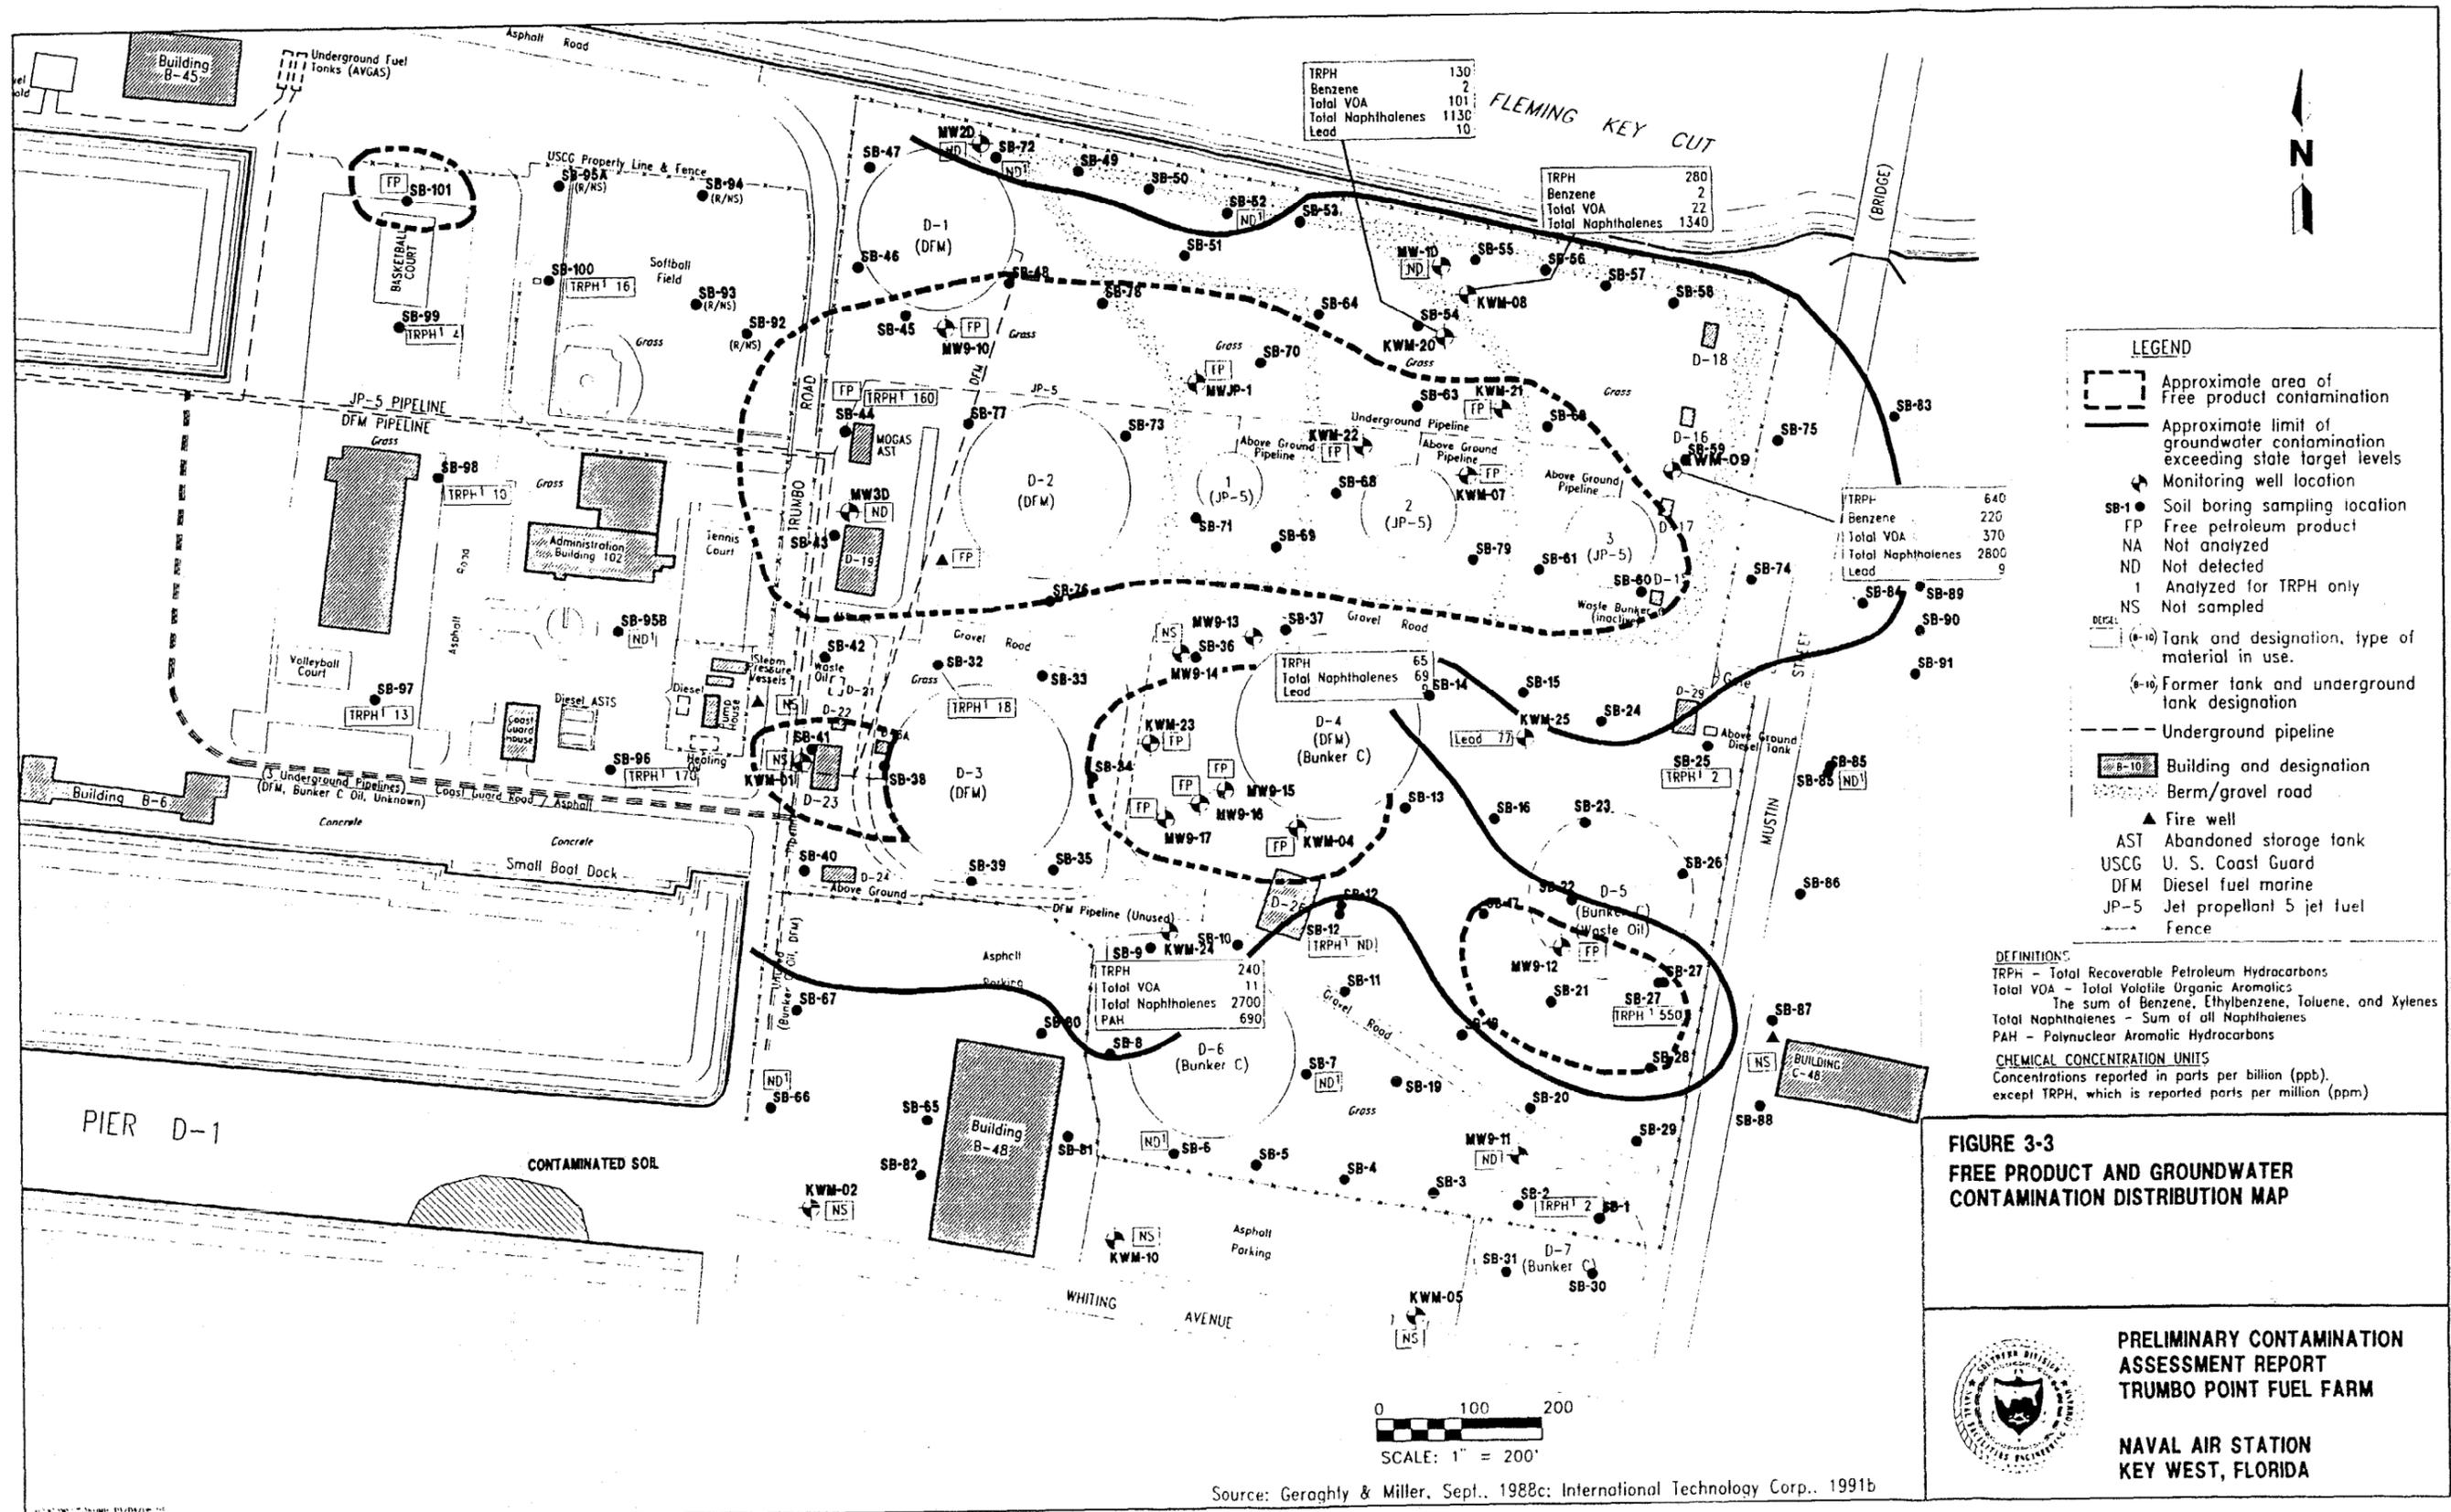

The approximate areal extent of free product in soil and groundwater is shown on Figure 3-3. Free product is extensive in the northern part of the TPF around JP-5 tanks 1, 2, and 3 and DFM tank D-2. Current data indicate that free product does not extend to the seawall. Free product appears to extend west to the USCG facility; however, it has not been delineated in this direction.

Free product was observed in three other areas of the TPF: the area along the south and west sides of DFM tank D-4; an area in the vicinity of the former DFM and waste oil tank D-5, near monitoring well MW9-12; and an area surrounding monitoring well KWM-01, which was reported to previously contain free product (Geraghty & Miller, 1987). Free product was also encountered at the USCG facility in SB-101 north of the basketball court.

3.2.2 Groundwater Contamination Analytical results indicate petroleum contamination in groundwater at the site. TRPH laboratory analyses for groundwater samples collected from soil borings are summarized in Table 3-2. Groundwater laboratory analyses for samples collected from monitoring wells are summarized in Table 3-3. Groundwater sample laboratory data sheets are attached in Appendix E, Groundwater Sample Laboratory Data.

Volatile organic aromatics (VOAs; including benzene), polynuclear aromatic hydrocarbons (PAHs; including naphthalenes), TRPH, and lead were detected in groundwater samples. Benzene, VOA, TRPH, and lead groundwater concentrations are herein compared to Class G-III groundwater target levels established by Chapter 17-770, FAC. Because no PAHs (including naphthalenes) target levels have been established for Class G-III groundwater, total naphthalenes concentrations will be compared to Class G-II target levels. Other PAH concentrations will be compared to State groundwater guidance concentrations (FDER, 1989a).

VOAs detected in groundwater samples include benzene, ethylbenzene, toluene, and xylenes. Benzene and total VOA concentrations exceeded the State target level of 200 parts per billion (ppb) in only the sample collected from monitoring well

¹ State target level for Class G-III groundwater (Chapter 17-770, Florida Administrative Code [FAC]).

² State target level for Class G-II groundwater (Chapter 17-770, FAC).

³ Groundwater guidance concentration (Florida Department of Environmental Regulation [FDER], 1989a).

Notes: Concentrations are in parts per billion, except TRPH which is reported in parts per million.

DUP = duplicate sample.

Total VOAs = total volatile organic aromatics (the sum of benzene, ethylbenzene, toluene, and xylenes).

Total naphthalenes is the sum of naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene.

Total PAHs = total polynuclear aromatic hydrocarbons, excluding naphthalenes.

TRPH = total recoverable petroleum hydrocarbons.

ND = not detected.

KWM-09, located near JP-5 tank 3. (Total VOAs is the sum of benzene, ethylbenzene, toluene, and xylenes.)

Total naphthalenes (the sum of naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene) were detected in concentrations exceeding the State G-II groundwater target level of 100 ppb in the samples collected from monitoring wells KWM-08, KWM-09, KWM-20, and KWM-24.

PAHs were detected in only the sample collected from monitoring well KWM-24, located near tank D-6. Fluorene and phenanthrene concentrations of 260 ppb and 430 ppb, respectively, exceed the State groundwater guidance concentration of 10 ppb.

TRPHs were detected at concentrations exceeding the Class G-III groundwater State target level of 5 ppm in the samples collected from soil borings SB-27, SB-32, and SB-44 at the TPF, and soil borings SB-96, SB-97, SB-98, and SB-100 at the USCG facility. TRPHs were also detected in concentrations above 5 ppm in samples collected from monitoring wells KWM-08, KWM-09, KWM-20, KWM-24, and MW9-13.

Lead concentrations exceeding the Class G-III State target level of 50 ppb was detected in only the sample collected from monitoring well KWM-25, located east of former DFM tank D-4.

3.2.2.1 Areal Extent of Groundwater Contamination The approximate areal extent of groundwater contamination is presented on Figure 3-3. Groundwater contamination is widespread throughout the TPF, except along the southern part of the site. The eastern and western extent of groundwater contamination, however, has not been adequately assessed. Groundwater contaminant migration in the northern part of the site is apparently being attenuated by the seawall. However, the potential exists for groundwater contaminant migration into Fleming Key Cut through cracks in the seawall (Geraghty & Miller, 1988c) or under the seawall.

Groundwater contamination detected at the USCG facility also has not been adequately assessed. Current data indicate, however, that contamination at the USCG facility may result from onsite petroleum product releases and contaminant migration from the TPF.

3.2.2.2 Vertical Extent of Groundwater Contamination Monitoring wells MW-1D through MW-3D were installed to assess possible contaminant migration below the seawall on the northern site boundary and the vertical extent of contamination on the western boundary of the TPF. No contaminants were detected in samples from the three vertical extent wells. Wells MW-1D, MW-2D, and MW-3D were screened over intervals ranging from 40 to 50 feet bls, which indicates that contamination in the vicinity of these three wells does not exceed 40 feet bls. Deep vertical migration of petroleum contamination does not appear to be occurring along the northern and western boundaries of the TPF; however, the extent of contaminant migration at depths ranging from 15 feet to 40 feet bls has not been evaluated. Also, there are little data to assess the vertical extent of groundwater contamination in other areas at the TPF, particularly areas where free product was observed.

4.0 CONCLUSIONS AND RECOMMENDATIONS

The PCA indicates the extent of soil petroleum contamination is widespread at the TFFF and the USCG facility. The extent of soil contamination at the TFFF appears to be adequately assessed. Excessive soil contamination along the northern and western perimeter of the TFFF may be a cause of concern for petroleum contamination in adjacent surface water sediment.

Areas of free product and groundwater contamination are widespread. The southern extent of groundwater contamination at the TFFF appears to be adequately assessed. Groundwater contamination is present along the northern and western perimeter of the TFFF and may be a cause of concern for petroleum contamination in adjacent surface water bodies. The western extent of groundwater contamination has not been adequately assessed.

Soil and groundwater contamination at the USCG facility has not been adequately assessed and also appears to be widespread. Contamination at the USCG facility appears to be from both onsite and offsite sources.

ABB-ES recommends that a contamination assessment (CA) be conducted at the TFFF and a PCA be conducted at the USCG facility to adequately assess the extent of soil and groundwater contamination so that recommendations can be made to address Florida Department of Environmental Protection (FDEP) cleanup criteria. ABB-ES recommends that the PCA at the USCG facility be completed first. The PCA would consist of a soil assessment only. Upon completion of the PCA, recommendations can be made for additional site investigation at the USCG facility. Assuming excessive soil contamination is discovered, ABB-ES would recommend that a CA be conducted at the USCG facility to assess the extent of groundwater contamination. The CA at the USCG facility could be conducted at the same time as the CA at the TFFF. If, however, the CA at the TFFF is completed and the corresponding contamination assessment report (CAR) is submitted to the FDEP before the extent of groundwater contamination has been adequately assessed at the USCG facility, it is unlikely that the CAR will be approved.

Completing the investigation will involve the following tasks:

- additional soil and groundwater assessment at the TFFF;
- surface sediment and surface water assessment at the TFFF;
- additional soil assessment at the USCG facility;
- aquifer characterization tests;
- a 24-hour tidal influence study;
- elevation and location survey of soil borings and monitoring wells;
- collection of soil and groundwater samples to support the evaluation of remedial design alternatives; and
- report preparation.

4.1 SOIL ASSESSMENT AT THE U.S. COAST GUARD (USCG) FACILITY. Approximately 48 additional soil borings will be drilled at the USCG facility to a depth of 6 feet bls to assess the extent of soil contamination at the USCG facility, particularly in areas of known or suspected contamination. Proposed soil boring locations are presented on Figure 4-1. Soil borings will be advanced with 3.75-inch diameter, solid-stem flight augers using a truck-mounted drill rig. Soil samples will be collected directly from the flight augers from depths of 0 to 2 feet bls, 2 to 4 feet bls, and 4 to 6 feet bls. Samples collected above the water table will be analyzed by OVA headspace techniques in accordance with Chapter 17-770, FAC, guidelines. Groundwater samples will be collected from each soil boring and screened for petroleum constituents using a gas chromatograph.

Soil OVA analyses will be used to assess the extent of petroleum contamination at the USCG facility so that the scope of a comprehensive contamination assessment can be estimated.

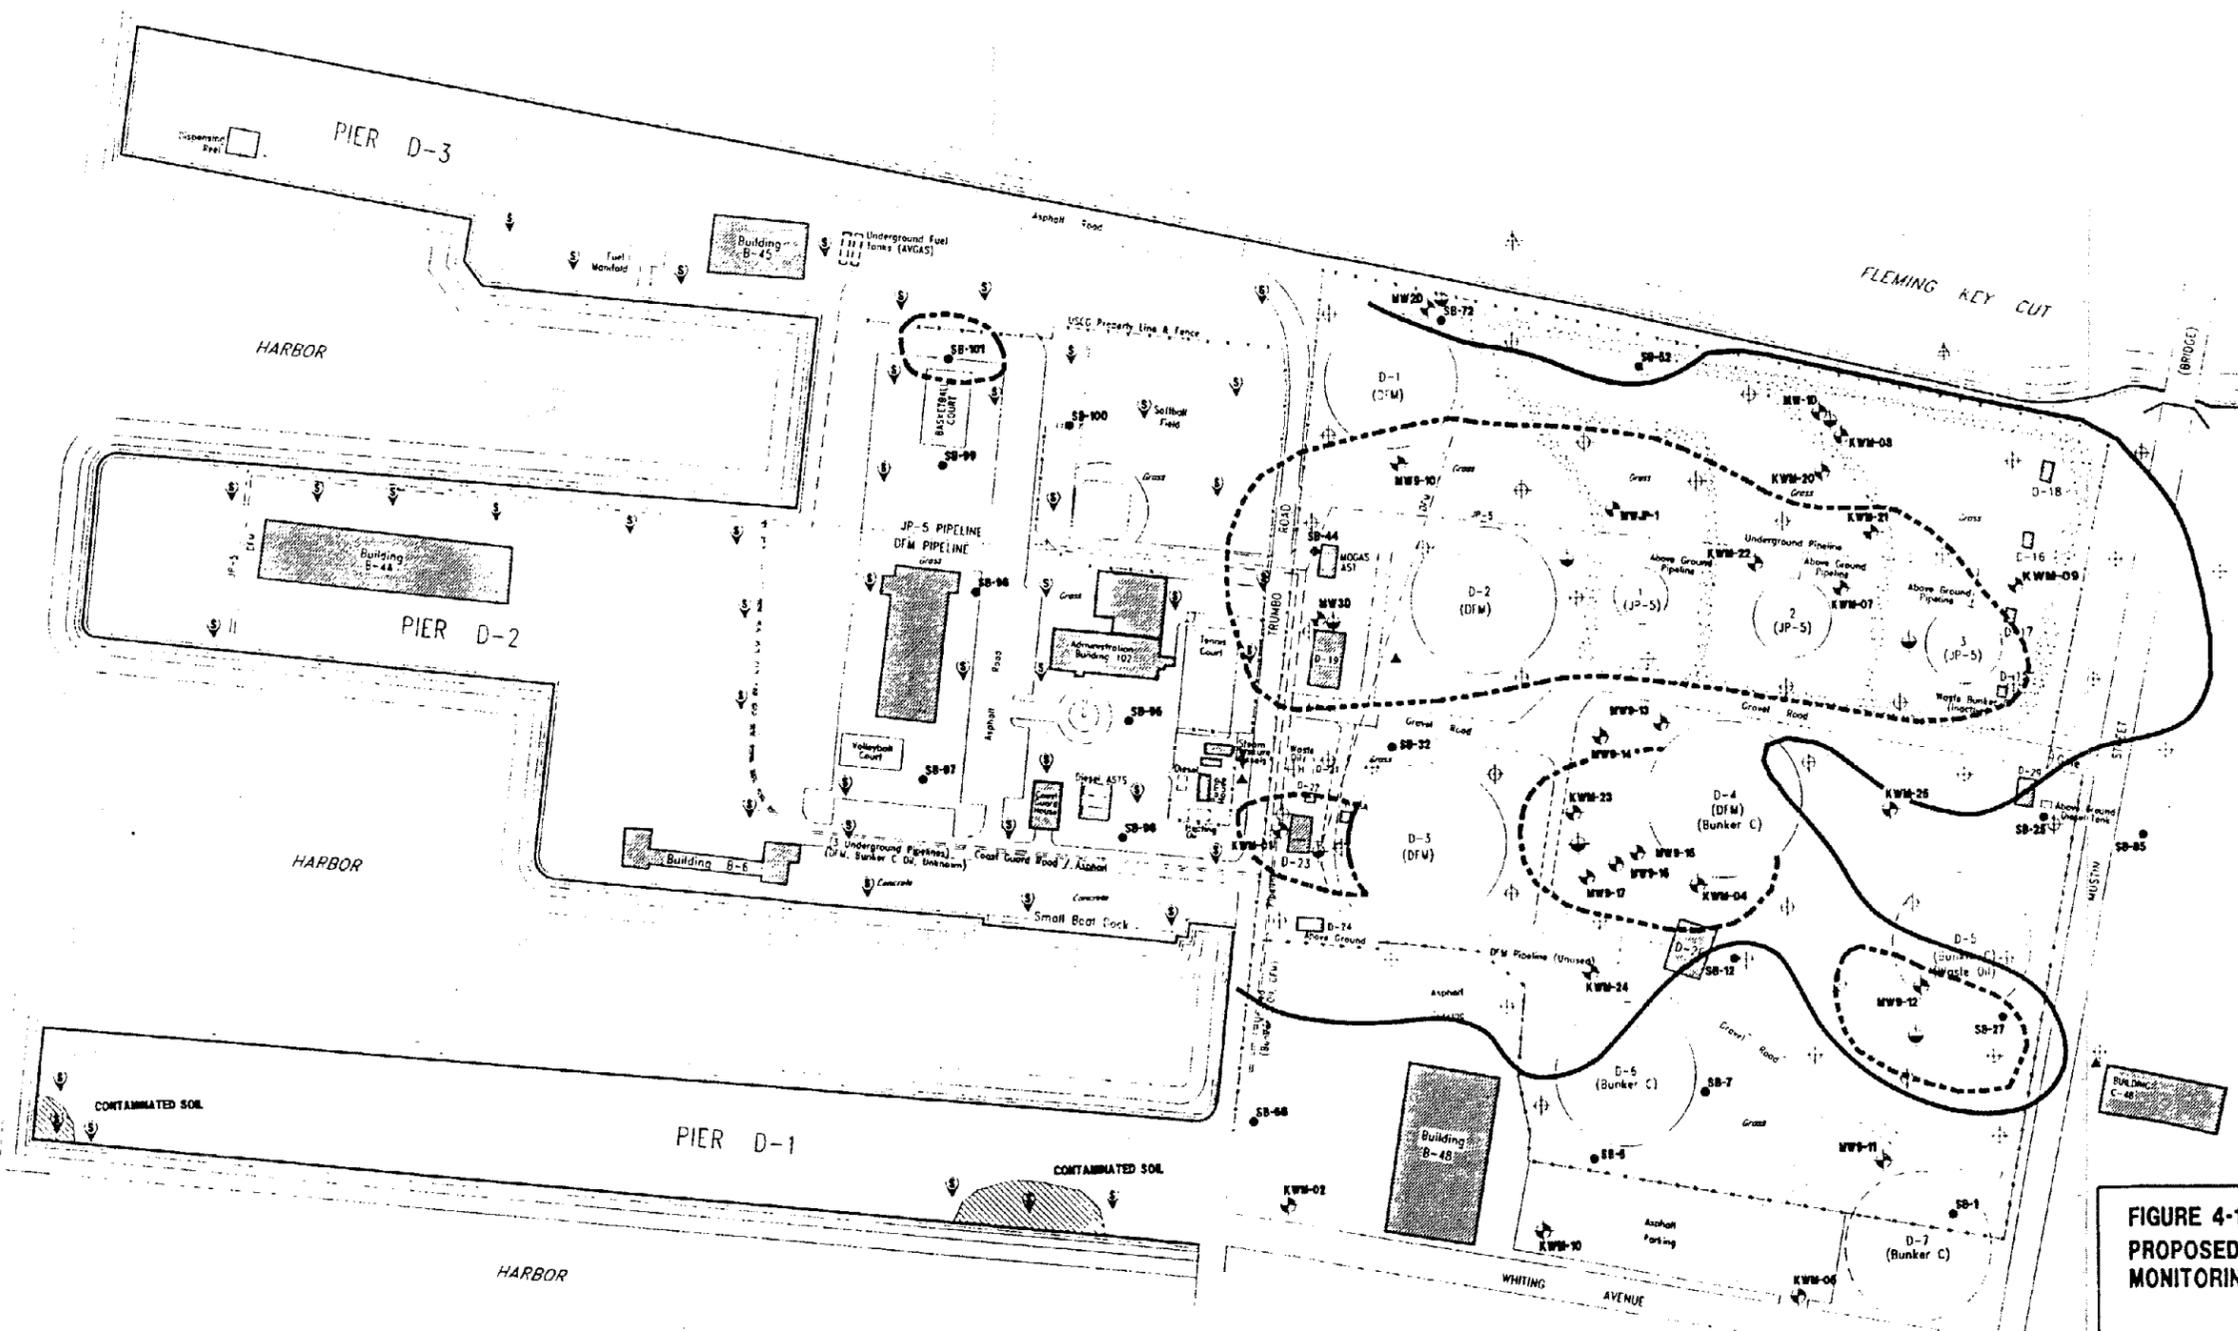

ABB-ES personnel and their subcontractors will coordinate efforts with the USCG facility and the NAS Key West Environmental Coordinator for proper disposal of contaminated soil. It will be the Navy's or USCG's responsibility to properly dispose hazardous soil.

4.2 GROUNDWATER ASSESSMENT AT THE TRUMBO POINT FUEL FARM (TPFF). The horizontal and vertical extent of groundwater contamination at the TPFF will be assessed by installing and developing groundwater monitoring wells and collecting groundwater samples for laboratory analyses. Approximately 50 shallow monitoring wells, 3 intermediate monitoring wells, and 4 deep monitoring wells are proposed.

Intermediate and deep wells are proposed in highly contaminated areas and will be clustered with shallow monitoring wells in the same general location. Proposed monitoring well locations are presented on Figure 4-1. Three intermediate wells are proposed to be installed at the locations of the three vertical extent wells, MW-1D through MW-3D. Two surface water and surface sediment samples will be collected along the seawall on the northern boundary of the site to assess the possibility of contaminant migration into Fleming Key Cut.

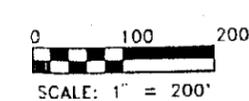

4.2.1 Monitoring Well Installation and Development Borings in which monitoring wells will be installed will be advanced with 4.25-inch inside diameter (ID), hollow-stem augers. Soil samples will be collected at 2-foot vertical intervals above the water table, and at 5-foot vertical intervals thereafter, until total depth is reached. Samples collected above the water table will be analyzed by OVA headspace techniques in accordance with Chapter 17-770, FAC, guidelines. Soils will be described and lithologic boring logs will be prepared.

Shallow wells will be installed to a depth of approximately 12 feet bls and will be constructed of 10 feet of 2-inch ID, 0.010-inch slotted, schedule 40, polyvinyl chloride (PVC) screen and flush-threaded riser. The screened interval will be approximately 2 to 12 feet bls. The annular space around the screened interval will be filled with a 20/30 grade silica filter pack to a depth approximately 6 inches above the top of the screen. A 3- to 4-inch thick bentonite seal will be placed above the filter pack. The remaining annular space will be grouted to land surface with portland cement. Typical shallow well installation details are presented on Figure 4-2.

NAVAL AIR STATION
KEY WEST, FLORIDA

Intermediate and deep wells will be constructed of the same materials as the shallow wells and will be installed inside 6-inch outside diameter (OD), Schedule 40 PVC surface casing. No confining layers are anticipated to be encountered; however, the intermediate and deep wells will be double cased to preclude the possibility of cross contamination with the upper part of the aquifer. The surface casing for intermediate and deep wells will extend to depths of approximately 20 feet bls and 40 feet bls, respectively. Intermediate wells will be screened from approximately 25 to 30 feet bls, and deep wells from 45 to 50 feet bls. A 20/30 grade silica filter pack will extend to at least 2 feet above the top of the screened interval. A 1-foot thick, fine-grained sand (or bentonite) seal will be placed above the filter pack, and the remaining annular space will be grouted to land surface with neat cement. Typical intermediate and deep monitoring well installation details are presented on Figure 4-3.

Monitoring wells will be fitted with a locking, watertight cap. Each well will be installed below grade in a subsurface traffic-bearing vault and protected with a metal manhole assembly.

Upon completion, newly installed monitoring wells will be developed by pumping a minimum of 10 well volumes until the purged water is clear and relatively free of sediment to provide a good hydraulic connection with the surrounding aquifer.

ABB-ES personnel and their subcontractors will coordinate efforts with the NAS Key West Environmental Coordinator to dispose contaminated drill cuttings and fluids. Proper hazardous waste disposal will be the Navy's responsibility.

4.2.2 Groundwater Sample Collection and Analyses Groundwater samples will be collected from all monitoring wells that do not contain free product. Groundwater samples will be collected with either Teflon™ bailers or disposable polyethylene bailers. The analytical sampling program will comply with the ABB-ES FDEP-approved Comprehensive Quality Assurance Plan (CompQAP).

Groundwater samples will be shipped to an FDEP-approved analytical laboratory. With the exceptions described in the next paragraph, groundwater samples will be analyzed for constituents of the kerosene and mixed products analytical group as defined in Chapter 17-770, FAC. Analyses will be performed for volatile organic halocarbons by U.S. Environmental Protection Agency (USEPA) Method 601, for VOAs by USEPA Method 602, for PAHs by USEPA Method 610, for TRPH by USEPA Method 418.1, and for lead by USEPA Method 239.2. Because ethylene dibromide (EDB) has not been detected during previous site investigations, it does not appear to be a contaminant of concern; therefore, EDB analyses will not be performed for groundwater samples collected during the CA.

Groundwater samples collected from monitoring wells in the vicinity of tanks D-5 and D-21, which were reportedly used for waste oil storage, will be analyzed for used oil constituents as described in Chapter 17-770, FAC. Analyses will be performed for total metal contents of arsenic, cadmium, chromium, and lead; for volatile organics by USEPA Method 624; for extractable organics by USEPA Method 625; and for TRPH by USEPA Method 418.1.

4.3 SOIL LABORATORY ANALYSES AT THE TRUMBO POINT FUEL FARM. Approximately 14 soil samples will be collected during the monitoring well installation phase. Of the 14, 10 samples will be collected in the vicinity of AST D-5 and 4 samples will be collected in the vicinity of AST D-21. The samples will be collected immediately above the water table (3 to 5 feet bls). The samples will be sent to an FDEP-approved analytical laboratory to be analyzed for used oil constituents as defined in Chapter 17-770, FAC. TRPH analyses will be performed by USEPA Method 418.1. Total metals analyses for arsenic, cadmium, chromium, and lead will be performed by USEPA Method 7060. One sample will be collected from the area of highest contamination associated with each tank and analyzed for the metals arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver by USEPA Method 1310, for volatile organics by USEPA Method 8240, for extractable organics by USEPA Method 8270, and for TRPH by USEPA Method 418.1.

4.4 AQUIFER CHARACTERIZATION. Aquifer tests will be conducted to estimate the hydraulic properties of the water table aquifer. Rising-head slug tests will be performed on a minimum of three shallow monitoring wells, two intermediate wells, and two deep wells to collect data for calculating hydraulic conductivity. Hydraulic conductivity will be calculated using the computer program AQTESOLV™ (Geraghty & Miller, 1989). The AQTESOLV™ program calculates hydraulic conductivity from slug test data following the methods of Bouwer and Rice (1976) for partially penetrating wells screened in unconfined aquifers.

Depth to groundwater will be measured and recorded in all monitoring wells at the site a minimum of two times on two separate dates not less than 1 month apart. Water levels will be measured during different moon phases to assess tidal effects on the direction of groundwater flow and the hydraulic gradient at the site.

4.5 TIDAL INFLUENCE STUDY. A 24-hour tidal influence study will be conducted during a new moon or full moon phase to assess the effect of tides on the direction of groundwater flow, hydraulic gradient, and pore water velocity.

4.6 ELEVATION AND LOCATION SURVEY. Soil boring locations will be surveyed by ABB-ES personnel. A Florida-licensed professional surveyor will survey the horizontal and vertical coordinates of each monitoring well, referenced to the U.S. Geological Survey (USGS) North American Datum of 1927 and incorporated into the NAS Key West coordinate grid system.

4.7 COLLECTION OF SAMPLES FOR REMEDIAL DESIGN. Soil and groundwater samples to be analyzed for remedial design parameters will be collected during the additional site assessment.

4.7.1 Soil Samples and Analyses for Remedial Design Approximately 10 soil samples will be collected in the vadose zone within contaminated areas. Vadose soil samples will be analyzed for the following parameters:

- total kjeldahl nitrogen, ammonia-nitrogen, and nitrate plus nitrite by USEPA Methods 351.3, 350.2, and 353.2, respectively;

- total phosphorus by USEPA Method 365.1;
- TOC and fraction of organic carbon (FOC) by USEPA Method 415.2;
- TRPH by USEPA Method 418.1;
- total bacteria and specific petroleum degraders by Modified USEPA Method 907B; and
- fingerprint by Modified USEPA Method 3550/8100 with major constituents tentatively identified.

Ten additional soil samples will be collected from representative strata below the water table. Five samples will be collected from the silty oolitic mud at depths of approximately 8 to 10 feet bls. The remaining five samples will be collected from the sandy limestone at depths of approximately 13 to 15 feet bls. These samples will be analyzed for FOC, TRPH, grain size distribution, and uniformity coefficient.

4.7.2 Groundwater Samples and Analyses for Remedial Design Approximately 10 groundwater samples will be collected from monitoring wells within contaminated areas and analyzed for the following parameters:

- iron (Fe^{2+}), manganese, chloride, sulfate, phosphorus, and sulfide by USEPA Methods 236.1, 243.1, 325.1, 375.4, 365.1, and 376.1 respectively;
- alkalinity, hardness, color, total solids, total suspended solids, and total dissolved solids by USEPA Methods 310.1, 130.2, 110.2, 160.3, 160.2, and 160.1, respectively;
- nitrate plus nitrite, total kjeldahl nitrogen, and ammonia-nitrogen by USEPA Methods 353.2, 351.3, and 350.2, respectively;
- TOC, dissolved oxygen, biological oxygen demand, and chemical oxygen demand (COD) by USEPA Methods 415.1, 360.1, 405.1, and 410.1/410.2, respectively;
- TRPH by USEPA Method 418.1;
- total bacteria and specific petroleum degraders by Modified USEPA Method 907B; and
- fingerprint by USEPA Method 8100 with major constituents tentatively identified.

4.8 REPORT PREPARATION. After completion of the soil assessment at the USCG facility, a PCAR will be prepared and submitted to the Navy for review and approval. Recommendations will be made concerning the need for additional site investigation. After completion of the field investigations at both facilities and receipt of laboratory analytical results, a CAR will be prepared for the entire site and submitted to the Navy for review and approval. The CAR will follow guidelines set forth by the FDEP (FDER, 1989b).

¹All sample depths are recorded in feet below land surface.

²All OVA readings are recorded in parts per million (ppm).

³The actual reading is determined by subtracting the filtered OVA reading from the unfiltered OVA reading.

⁴A monitoring well was installed in this soil boring location.

Notes: nm = not measured.

< = less than.
