## **EXECUTIVE SUMMARY**

---

The U.S. Department of the Navy (Navy) has completed a Remedial Investigation (RI) for Installation Restoration (IR) Site 34, at the former Naval Air Station (NAS) Alameda in Alameda, California. NAS Alameda is now known as Alameda Point. The purpose of this RI was to (1) collect data to eliminate previously identified data gaps; (2) evaluate the nature and extent of soil and groundwater contamination; and (3) assess the risk to human health and the environment at IR Site 34. Data generated during the RI were used to complete the characterization of soil and groundwater conditions at IR Site 34 and to support risk estimate calculations for a baseline human health risk assessment (HHRA) and a screening-level ecological risk assessment (SLERA). This RI was performed as part of the ongoing activities and responsibilities required under the Navy's IR Program.

The following sections describe the site and its history, and summarize the future land use; previous investigations; the results of the evaluations of nature and extent of contamination, fate and transport, and risk to humans and ecological receptors; and the conclusions and recommendations based on the RI and risk assessment data presented in Sections 1.0 through 7.0 of the RI Report.

### **SITE DESCRIPTION AND HISTORY**

IR Site 34 is located in the north-central portion of Alameda Point, adjacent to the Oakland Inner Harbor (see Figure 1-2). IR Site 34 is a 4.18-acre area that is a partially paved, relatively flat open space. IR Site 34 was a Naval Air Rework Facility (NARF) used to maintain base equipment such as scaffolding and other apparatus. The site was used primarily for painting services, storage, wood and metal shop activities, and sandblasting activities. IR Site 34 formerly contained several structures, including 12 buildings (331, 330, 343, 475, 344, 510, 474, 477, 604, 476, 479, and 472) and intervening open areas; seven aboveground storage tanks (AST) (330A, 330B, 344A, 344B, 344C, 344D, and 331); generator accumulation points (GAP) 78 and 79; 15 transformers; and an aviation gasoline fuel line. All buildings, ASTs, GAPs, transformers, and fuel lines were removed between 1996 and 2000, except for their concrete pads. Figure 1-3 of the RI Report shows the historical and existing site features at IR Site 34.

### **FUTURE LAND USE**

IR Site 34 is considered part of the Northwest Territories. The Northwest Territories are designated as Public Open Space and Parks (City of Alameda 2003). Future use of IR Site 34 is designated as part of a golf course area. In addition, Site 34 has been identified as a tideland trust area that is subject to the limitations expressed in the Coastal Zone Management Act, including a restriction on residential use.

## PREVIOUS INVESTIGATIONS

Numerous investigations have been conducted at IR Site 34, including the Phase 1 environmental baseline survey (EBS) (Environmental Resources Management West, Inc. [ERM-West] 1994), Phase 2a and 2b EBS (International Technology Corporation [IT Corp.] 2001), fuel pipeline removal action (IT Corp. 1999), and a site inspection (Bechtel Environmental, Inc. 2003). Based on the results of these investigations, the Navy decided that an RI was necessary at IR Site 34. Fieldwork for the RI was conducted from February 2006 through March 2007 (SulTech 2006). The fieldwork consisted of two separate mobilizations. During the first mobilization, modified grid samples were collected from 19 sampling locations, fence line samples were collected from 13 sampling locations, hotspot samples were collected from 20 sampling locations, paint waste samples were collected from 24 sampling locations, off-site samples at adjacent parcels were collected from 2 sampling locations, and groundwater samples were collected from 19 sampling locations. Field activities also included the installation of four shallow and one deep monitoring wells, aquifer testing, and two rounds of groundwater sampling. The purpose of the second mobilization was to obtain more data on potential migration of chemicals to groundwater and to clarify some of the analytical results from the first mobilization of the RI fieldwork.

## NATURE AND EXTENT OF CONTAMINATION – SOIL AND GROUNDWATER

The RI report presents the analytical results of five investigations completed at IR Site 34, as discussed in the previous section. Data collected during these previous investigations were used to evaluate site conditions for the HHRA and SLERA.

Samples were analyzed for metals, volatile organic compounds (VOC), semivolatile compounds (SVOC), polycyclic aromatic hydrocarbons (PAH), pesticides, polychlorinated biphenyls (PCB), and total petroleum hydrocarbons (TPH).

Soil data collected during these investigations were screened against a number of comparison criteria, including U.S. Environmental Protection Agency (EPA) and California-modified residential preliminary remediation goals (PRGs), EPA and California-modified industrial PRGs, San Francisco Bay Regional Water Quality Control Board (Water Board) environmental screening levels (ESL) (for diesel, gasoline, and motor oil), background concentrations of metals in soil samples from the Pink Fill Area and screening level established by the Navy and agencies for PAHs as average benzo(a)pyrene [B(a)P] equivalent concentrations. Groundwater data collected during these investigations were screened against EPA tap water PRGs, background concentrations for metals in shallow groundwater samples from the Alameda Point, and Water Board ESLs to evaluate potential vapor intrusion concerns for residential land use in high-permeability vadose zone soils. Using residential PRGs, ESLs, and EPA tap water PRGs to estimate the nature and extent of contamination at IR Site 34 may be an overly conservative comparison given the intended future use as a golf course and the restriction against residential use of tidelands trust areas.

## Summary of Soil Nature and Extent

For the purposes of this RI, contamination is defined as a chemical detected in an environmental sample at IR Site 34 at a concentration exceeding comparison criteria. Metals, VOCs, PAHs, pesticides, PCBs, and TPH were detected at concentrations above comparison criteria in soil samples collected at IR Site 34. Only the following seven chemicals were detected above comparison criteria in more than 10 percent of the samples:

- Metals (arsenic, iron, lead)
- PCBs (Aroclor-1254, Aroclor-1260)
- TPH (as diesel, as motor oil)

Although PAHs were detected above comparison criteria in less than 10 percent of the samples and the evaluation of PAHs relative to B(a)P equivalents showed the site-wide average B(a)P equivalent concentration is below the comparison criteria of 0.62 milligram per kilogram (mg/kg), the site-wide average concentration is influenced by an EPA B(a)P-equivalent value of 8.4 mg/kg and an Office of Environmental Health Hazard Assessment (OEHHA) B(a)P-equivalent value of 9.5 mg/kg in a sample of anomalous soil collected above a black clayey sand with a strong diesel odor at location DP16 (north of Building 331).

In addition to exceeding comparison criteria in more than 10 percent of the samples, these seven chemicals, and the following additional chemicals were determined to likely pose potential risk, based on a residential exposure (see the HHRA, Section 6.0)

- PCBs (Aroclor-1248, 1268)
- Pesticides (dieldrin, heptachlor epoxide),
- SVOC (naphthalene)
- VOCs (1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-dichlorobenzene (DCB), and 1,4-DCB)

After taking into consideration that further evaluation in a feasibility study (FS) is based on the risk assessments and reviewing the distribution of concentrations for those chemicals driving risk, residual soil contamination appears to be collocated and limited to six specific areas of concern (AOC) at IR Site 34. The list below (as shown on Figure 4-14) indicates which chemicals are present at each AOC at concentrations potentially posing risk and the likely historical sources of the contaminants.

- **Northwest corner of the site, near the former railroad and former Building 510:** arsenic, PCBs, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to site use and historical sandblasting in former Building 510. Oils and solvents may have been released from sandblasting equipment.
- **North of Building 331:** arsenic, lead, PCBs, naphthalene, and TPH as diesel. Residual contamination in this area appears to be related to use of oils and solvents for woodwork at the former building and metal working at Building 330 to the west.
- **Along the former railroad and south of former Building 331:** lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to site use, historical releases from former AST 331, and use of oils and solvents for woodwork at the former building.
- **Southwest corner of former Building 343 and east of former Building 475:** PCBs. Residual contamination in this area appears to be related to the transformer formerly located in Building 475 and the release of oils from sandblasting equipment.
- **Southeast corner of former Building 343 and northeast corner of former Building 344:** iron, lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to historical releases from former AST 344D, sandblasting of lead-based paints, and lubricants used for sheet metal fabrication. The floor of former Building 343 was rusted, which may have released metals to nearby soil.
- **Southwest corner of the site:** pesticides, PCBs, and VOCs. This area was used between 1995 and 1997 for temporary storage of PCB- and lead-contaminated soil excavated from IR Site 15 (see Section 1.3.3.1). Residual contamination in this area may be related to operation of the temporary storage and treatment area (TSTA) and application of pesticides for weed control.

## Summary of Groundwater Nature and Extent

Metals, VOCs, and PAHs were detected at concentrations exceeding comparison criteria in groundwater samples collected at IR Site 34. Diesel- and motor oil-range petroleum hydrocarbons had a greater than 50 percent detection frequency across IR Site 34. The most likely sources of these chemicals are from the disposal of used sandblasting and paint grit; painting activities; chemical storage; sheet metal fabrication; spills near the GAP; leaks from ASTs; and application of chemicals for weed control. However, all of these potential sources were removed after closure of NAS Alameda in 1997. Groundwater contamination at IR Site 34 appears to be confined to several specific areas, as listed below.

- Near the open area in the western-central portion of the site

- Near former Buildings 331, 474, 476, and 604; former GAP 78; the former petroleum fuel pipeline in the southwest corner of the site; and former ASTs 330B, 331, 344A, 344B, and 344D.

These areas have been identified using EPA tap water PRGs as a preliminary screening tool, even though groundwater beneath IR Site 34 is not a potential drinking water source.

## **CHEMICAL FATE AND TRANSPORT**

Potential transport mechanisms that may allow chemicals at IR Site 34 to migrate were evaluated. The most significant transport mechanisms are listed below.

- Migration of chemicals by leaching from vadose zone soils to groundwater by infiltration of rainwater, and to a lesser extent by seasonal and tidal fluctuations in groundwater elevations.
- Horizontal migration of chemicals toward the Oakland Inner Harbor because of groundwater flow and tidal fluctuation.
- Migration of chemicals because of groundwater flow into and along storm sewers. However, based on groundwater data collected during the RI investigation and chemical distribution at the site, it appears that the chemicals are not migrating along this pathway.

## **BASELINE HUMAN HEALTH AND RISK ASSESSMENT**

The baseline HHRA estimated potential risks for future hypothetical commercial/industrial workers, construction workers, recreational users, and residents at IR Site 34. The HHRA estimated risks using EPA and California Department of Toxic Substances Control (DTSC) toxicity values assuming both a reasonable maximum exposure (RME) scenario and a central tendency exposure (CTE) scenario. RME is intended to represent the upper end of exposure, whereas CTE represents an average exposure. Table ES-1 presents the total RME risks estimated using EPA toxicity values. Section 6.0 and Appendix H discuss potential risks estimated using DTSC toxicity values and risks estimated under the CTE scenario.

IR Site 34 is currently unoccupied land, thus receptors are not present at the site. The planned reuse of this area is recreational and includes the development of a golf course. IR Site 34 has been identified as a tidelands trust area that is subject to the limitations expressed in the Coastal Zone Management Act, including a restriction on residential use. Although planned reuse of IR Site 34 is recreational and the future residential scenario evaluated in the HHRA is unlikely, the HHRA evaluated a residential scenario to provide alternative risk estimates for unrestricted reuse of the site and to support risk management decisions for the site.

Table ES-1 identifies the risk drivers in soil and groundwater. The HHRA identified a chemical of potential concern (COPC) as a risk driver when the COPC-specific cancer risk exceeded  $1 \times 10^{-6}$  or the COPC-specific hazard quotient (HQ) exceeded 1. Lead was identified as a risk driver because blood-lead modeling resulted in 99th percentile concentrations greater than 10 micrograms per deciliter for adult and child residents. As summarized below, each risk driver was evaluated to determine whether a risk driver should be considered in an FS.

### **Human Health Risk Drivers**

The RI Report evaluated each risk driver to determine whether a risk driver should be considered in an FS. As described in Section 6.4, factors considered when including or excluding chemicals for further considerations in FS included background concentrations, frequency of detection, exposure pathways, the B(a)P-equivalent screening level, and sampling methodology (grab samples).

### **Human Health Risk Drivers in Soil Recommended for Consideration in a Feasibility Study**

The table below lists the risk drivers recommended for further consideration in an FS.

<b>Risk Drivers in Soil Recommended for Further Consideration in an FS</b>			
1,2,3-Trichlorobenzene	1,4-DCB	Aroclor-1260	Iron
1,2,4-Trichlorobenzene	Aroclor-1268	Arsenic	Lead
1,2,4-Trimethylbenzene	Aroclor-1248	Dieldrin	Naphthalene
1,2-DCB	Aroclor-1254	Heptachlor epoxide	

As shown on Table ES-1, potential cancer risks from 1,4-DCB ( $1.4 \times 10^{-4}$ ) contributes the most to the total cancer risk ( $2.7 \times 10^{-4}$ ) under the residential scenario. Potential cancer risks were less than  $4 \times 10^{-5}$  for all other risk drivers. The noncancer hazard quotient of naphthalene (48), 1,2,4-trichlorobenzene (18), and 1,2,3-trichlorobenzene (5.2) contributes the most to the total hazard index (82) under the residential scenario. The hazard quotients were less than 2 for all other risk drivers under the residential scenario.

The potential for human health effects caused by lead is typically estimated on the basis of blood-lead concentrations. Blood-lead modeling resulted in 99th percentile concentrations greater than 10 micrograms per deciliter ( $\mu\text{g}/\text{dL}$ ) for the adult and child residents. Lead concentrations were greater than the background concentration of 37.7 mg/kg in 45 of 105 soil samples. Lead concentrations ranged from 1.1 mg/kg to 21,000 mg/kg and the average was 520 mg/kg. Lead concentrations exceeded the California-modified residential PRG of 150 mg/kg in 29 soil samples and the EPA industrial PRG of 800 mg/kg in 7 soil samples.

Although the RI recommends consideration in an FS for the chemicals listed above, potential risks for many of these chemicals are based on very conservative assumptions that may have overestimated risks and include risk drivers for hypothetical residential scenarios that are

unlikely. For example, 1,2,3-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and iron were only risk drivers under the residential scenario. As discussed previously, residential development of IR Site 34 is unlikely.

Many conservative assumptions were used that may have overestimated the risks. For example, the VOCs (1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and 1,4-DCB) were only detected in 1 of 32 soil samples, and all at the same location (DP2). Thus, estimated risks for these VOCs are not representative of site-wide conditions, but rather represent the potential risks at only one soil sampling location. The risk from naphthalene is also based on the maximum detected concentration. However, these VOCs are recommended for consideration in an FS because they contribute the most to the total cancer risks and noncancer hazard index. In addition, these VOCs are collocated with (though likely unrelated to) PCBs that are also recommended for further consideration in an FS.

As another example, EPA derived a provisional reference dose for iron based on a specific metabolic disorder. Incorporation of this reference dose resulted in a chemical-specific HQ exceeding 1. The significance of this result is uncertain because ongoing debate over this provisional reference dose has not resulted in its incorporation into the EPA Integrated Risk Information System (IRIS).

**Human Health Risk Drivers in Soil not Recommended for Consideration in a Feasibility Study**

The table below lists the risk drivers in soil not recommended for further consideration in an FS.

Risk Drivers in Soil not Recommended for Further Consideration in an FS			
Soil			
4-Nitroaniline	B(a)P	Dibenzo(a,h)anthracene	4-Nitroaniline
Aluminum	Benzo(b)fluoranthene	Indeno(1,2,3-cd)pyrene	Aluminum
Benzo(a)anthracene	Bis(2-ethylhexyl)phthalate	Manganese	Benzo(a)anthracene

Most of the risk from 4-nitroaniline and bis(2-ethylhexyl)phthalate was from the homegrown produce pathway and both were identified as risk drivers only for the future hypothetical resident. The HHRA used conservative assumptions to estimate risks for the homegrown produce pathway, so the risks for these risk drivers are likely overestimated. In addition, 4-nitroaniline was only detected in 1 of 24 samples (with a maximum detected concentration of 0.62 mg/kg) and does not exceed the residential soil PRG of 37 mg/kg. Bis(2-ethylhexyl)phthalate was only detected in 5 of 38 soil samples (with a maximum detected concentration of 14 mg/kg) and does not exceed the residential soil PRG of 35 mg/kg. These two risk drivers are not collocated with other chemicals exceeding comparison criteria, and bis(2-ethylhexyl)phthalate is known to be a common laboratory contaminant. The cancer risk to a hypothetical future hypothetical resident from exposure to 4-nitroaniline in surface and subsurface soil is  $1.4 \times 10^{-6}$ . The cancer risk to a hypothetical future hypothetical resident from

exposure to bis(2-ethylhexyl)phthalate in surface soil is  $3.3 \times 10^{-6}$  and  $2.2 \times 10^{-6}$  in subsurface soil. The results for 4-nitroaniline and bis(2-ethylhexyl)phthalate are all at the lower end of the risk management range of  $10^{-6}$  to  $10^{-4}$ . In addition, the noncancer hazards for both of these risk drivers in surface and subsurface soil are less than the noncancer threshold of 1.0. Thus, consideration of 4-nitroaniline and bis(2-ethylhexyl)phthalate in an FS is not recommended.

Aluminum and manganese were the only risk drivers for the future hypothetical construction worker. Historical activities and the distribution of aluminum and manganese concentrations exceeding background concentrations do not indicate aluminum and manganese are related to Navy activities at IR Site 34. Thus, the RI Report does not recommend consideration of aluminum and manganese in an FS.

PAHs were identified as risk drivers; however, previous agreements between the Navy and regulatory agencies established a screening level of 0.62 milligram per kilogram (mg/kg) for an average B(a)P equivalent concentration. The average EPA and OEHHA B(a)P equivalent concentrations (0.47 mg/kg and 0.52 mg/kg, respectively) are below the established screening level of 0.62 mg/kg. The site-wide average concentrations are influenced by an EPA B(a)P-equivalent value of 8.4 mg/kg and an OEHHA B(a)P-equivalent value of 9.5 mg/kg in a sample of anomalous soil collected above a black clayey sand with a strong diesel odor at location DP16. The site-wide average EPA and OEHHA B(a)P equivalent concentrations without this sample are 0.23 mg/kg and 0.25 mg/kg, respectively. Elevated concentrations of PAHs were confined to individual sample locations and do not appear to represent large masses of contaminated media. Thus, the RI Report does not recommend further consideration of PAHs in an FS.

#### ***Human Health Risk Drivers in Groundwater***

The only risk driver identified in groundwater is trichloroethene (TCE). The vapor intrusion pathway accounted for 98 percent of the estimated cancer risk for TCE. Many of the exposure assumptions used to evaluate the vapor intrusion pathway are highly conservative and may have overestimated risks. For example, the vapor intrusion models assumed steady-state concentrations of volatile COPCs in the subsurface for the entire duration of exposure. The assumption of steady-state concentrations for extended durations is conservative because, over time, chemicals may migrate from one medium to another or from one location to another within a particular medium. In addition, the assumption of steady-state concentrations for the entire duration of exposure assumes that reductions in concentrations that would likely occur through transformation or degradation processes—such as hydrolysis, photolysis, and biodegradation—do not occur. TCE was detected in 8 of 30 groundwater samples. The two highest TCE concentrations (0.6 micrograms per liter [ $\mu\text{g/L}$ ]) were detected in grab groundwater samples collected using direct-push technologies. The highest TCE concentration detected in a monitoring well was an estimated value (J-qualified) of 0.2  $\mu\text{g/L}$ . Thus, the RI Report does not recommend further consideration of TCE in an FS.

Groundwater at IR Site 34 is not reasonably anticipated to serve as a public drinking water supply. Accordingly, the HHRA did not quantitatively evaluate domestic use of groundwater

because it considers domestic use of groundwater to be an incomplete pathway. Thus, no further evaluation of groundwater is required and no action is recommended.

### **SCREENING-LEVEL ECOLOGICAL RISK ASSESSMENT AND STEP 3A RISK REFINEMENT**

A SLERA was conducted as part of the RI to evaluate potential risks to ecological receptors from chemicals in soil and groundwater at IR Site 34. Direct soil ingestion, ingestions via the food chain, and horizontal migration of groundwater to surface water were identified as potentially complete exposure pathways for ecological receptors. Tier 1 of the ecological risk assessment process was completed to calculate screening-level HQs. Tier 1, composed of two steps, used existing data and conservative assumptions to evaluate risk at the site. In Step 1, Exposure Evaluation, potentially complete exposure pathways were examined to determine if links between site chemicals and ecological receptors exist at IR Site 34. In Step 2, Risk Characterization, risk was estimated for chemicals with potentially complete exposure pathways identified in Step 1. Risk for terrestrial receptors was estimated based on the HQ approach, and effects on aquatic life were qualitatively evaluated by comparing chemicals in groundwater to four sets of primary aquatic comparison criteria potentially applicable to the site (threshold criteria).

The data evaluated in Steps 1 and 2 indicated chemicals in soil and groundwater at IR Site 34 may pose unacceptable risk to receptors; therefore, the Navy initiated the risk refinement step (Step 3a) of the baseline ERA. In order to generate a slightly more realistic estimate of risk, while maintaining the conservative nature of the SLERA, a Step 3a risk refinement was conducted for any chemical of potential ecological concern (COPEC) with an HQ greater than 1 and a frequency of detection of 5 percent or greater, COPECs without toxicity reference values (TRV) and groundwater COPECs that exceeded the four sets of aquatic threshold criteria. Refined risk estimates were not prepared for several pesticides and the PCB Aroclor-1248 that had HQs greater than 1 because their frequency of detection is less than 5 percent. For terrestrial receptors, risk estimations were refined by using the lower of the 95 percent upper confidence limit of the mean (95UCL) and the maximum detected concentration as the exposure point concentration and modifying the exposure factors to reflect more realistic values for each receptor. For aquatic life, those groundwater COPECs retained from the initial screening were evaluated chemical by chemical based upon the maximum detected concentration and 95UCL compared to the four sets of threshold criteria; a supplemental literature search for additional criteria; the sample location (for example, the first water-bearing zone [FWBZ] versus the second water-bearing zone [SWBZ], at locations with other elevated metals); sampling date; sampling methods (for example, monitoring well versus direct push), and the groundwater data set (for example, exposure point concentration driven by outlier). The SLERA intentionally incorporates conservative assumptions to identify any potential risk from site-related chemicals to ecological receptors. As a result, this assessment likely overestimates the risk associated with the risk

Based on the results of the Step 3a risk refinement, the following chemical was identified as a risk driver in soil at IR Site 34.

- Lead

No risk drivers were identified in groundwater at Site 34.

Although lead may contribute to ecological risk at IR Site 34, based on the SLERA, a baseline ecological risk assessment (ERA) is not recommended because the SLERA likely overestimated risk, there is a lack of current suitable habitat, and future land use would not generate much ideal habitat for wildlife. IR Site 34 currently consists of predominantly Intensively Developed area and two potential wetland areas. Intensively Developed areas have little vegetation and typical urban wildlife, such as California ground squirrel, scrub jays, and American robins, may be observed in these areas but to a lesser extent than in the landscaped/developed areas, because less foraging habitat is available in these areas. The potential wetland areas provide minimal habitat to support plant and invertebrate populations and do not provide suitable habitat for small mammals. In addition, because of high marine vessel activity in the Oakland Inner Harbor it is unlikely that this area will be used by nesting birds.

Site-related chemicals in soil and groundwater at IR Site 34 are not expected to affect the potential wetland areas or the Oakland Inner Harbor for the following reasons. It is unlikely that groundwater or surface water runoff from IR Site 34 would affect the potential seasonal wetland located within the southwest corner of the site because the site topography would prevent it from reaching this potential wetland. Although surface water generally flows towards the wetland located to the north of the site, precipitation typically evaporates into the atmosphere, infiltrates to groundwater, or runs off into the storm drain system. The potential wetland is also not likely to be affected by site-related chemicals in groundwater because it lies between a series of parallel rock riprap walls that together form a terrace of land that is the shoreline and is tidally inundated at such a frequency as to not present suitable habitat for small mammals, dilution would occur as groundwater mixes with surface water (Oakland Inner Harbor), and groundwater COPECs were identified based on the assumption that no dilution, retardation, or degradation will occur between the location where the groundwater risk drivers were detected and the Oakland Inner Harbor/wetland. In addition, the low-flow velocities of groundwater, low concentrations of VOCs in groundwater, high potential for retardation along the groundwater flow path, and tidal action and surface water flow that create a mixing zone at the interface with the Oakland Inner Harbor suggest that chemicals will not discharge to the Oakland Inner Harbor at concentrations of concern.

Following further evaluation of the COPECs, this assessment was determined to likely overestimate risk to terrestrial and aquatic receptors (including the wetland); therefore, further investigation or assessment of ecological risk from soils and groundwater at IR Site 34 is not recommended.

## **RECOMMENDATIONS**

Based on the conclusions of the evaluations discussed above, additional site characterization of soil or groundwater is unnecessary at IR Site 34 to complete the RI. The nature and extent of

soil and groundwater contamination has been adequately characterized and the data were found to be sufficient to conduct an HHRA and SLERA.

The Navy recommends the chemicals listed below and the five AOCs where contamination appears to be limited to be further considered in an FS (See Figure 8-3). No action is recommended for groundwater or the AOC located in the southwest corner of former Building 343 and east of former Building 475. Although PCBs were detected in samples collected within this area at concentrations greater than the residential PRGs, this area is not specifically identified for further evaluation in an FS because of the relatively low risk of PCBs based on the HHRA.

- **Northwest corner of the site, near the former railroad and former Building 510:** arsenic, PCBs, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to site use and historical sandblasting in former Building 510. Oils and solvents may have been released from sandblasting equipment.
- **North of Building 331:** arsenic, lead, PCBs, and naphthalene. Residual contamination in this area appears to be related to use of oils and solvents for woodwork at the former building.
- **Along the former railroad and south of former Building 331:** lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to site use, historical releases from former AST 331, and use of oils and solvents for woodwork at the former building.
- **Southeast corner of former Building 343 and northeast corner of former Building 344:** iron, lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to historical releases from former AST 344D, sandblasting of lead-based paints, and lubricants used for sheet metal fabrication. The floor of former Building 343 was rusted, which may have released metals to nearby soil.
- **Southwest corner of the site:** pesticides, PCBs, and VOCs (1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and 1,4-DCB). This area was used between 1995 and 1997 for temporary storage of PCB- and lead-contaminated soil excavated from IR Site 15 (see Section 1.3.3.1). Residual contamination in this area may be related to operation of the TSTA and application of pesticides for weed control.

The Navy recommends an FS be prepared to evaluate options to address contamination at IR Site 34 posing a risk to human health. The FS should consider the future land use in evaluating these options. In addition, the Navy recommends the following additional sampling for inclusion in the FS:

- Sampling within the vicinity of DP02 to verify previous VOC results

- Sampling of soil and groundwater for fuel-related contamination north of Building 331 and near sampling location DP16, where a layer of black sand with a strong diesel odor was identified

Additionally, concentrations of TPH were detected above the comparison criteria, and low-level concentrations of TPH were detected across IR Site 34. Although TPH is not a contaminant under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), it was addressed in the nature and extent evaluation because fuels and lubricants were used at various locations across the site and an objective of this RI was to meet TPH closure requirements. At Site 34, TPH-affected soil (mostly diesel and motor oil) appears to be located at isolated locations near former ASTs and buildings where lubricants were used. Based on the current data, TPH in soil is collocated with CERCLA chemicals in soil and will be addressed with the CERCLA chemicals identified above in the FS. Further consideration of TPH-affected soil in the TPH program is not recommended.

## 1.0 INTRODUCTION

The U.S. Department of the Navy (Navy) has completed a Remedial Investigation (RI) for Installation Restoration (IR) Site 34, at the former Naval Air Station (NAS) Alameda in Alameda, California. NAS Alameda is now known as Alameda Point. This report presents geologic, hydrologic, and chemical data collected during the Phase 1 Environmental Baseline Survey (EBS) (Environmental Resources Management West, Inc. [ERM-West] 1994), the Phases 2a and 2b EBS (International Technology Corporation [IT Corp.] 2001), a fuel pipeline removal action (IT Corp. 1999), a Site Inspection (SI) (Bechtel Environmental, Inc. 2003), and the RI sampling events (SulTech 2006). Data generated during these investigations were used to complete the characterization of soil and groundwater conditions at IR Site 34 and to support risk estimate calculations for human and ecological receptors. This RI Report summarizes the findings of the RI and provides conclusions and recommendation for IR Site 34.

The remainder of this section discusses the purpose of the RI for IR Site 34, presents the organization of this report, and summarizes the background of the site.

### 1.1 PURPOSE

The purpose of this RI was to (1) collect data to eliminate previously identified data gaps; (2) evaluate the nature and extent of soil and groundwater contamination; and (3) assess the risk to human health and the environment at IR Site 34. This report documents the approach used to conduct the RI for IR Site 34 and the results of the field investigations and risk assessments, and recommends further assessment in a Feasibility Study (FS), if necessary, so an informed risk management decision can be made about the need for response actions (U.S. Environmental Protection Agency [EPA] 1988b). The following list provides the specific objectives of the RI for IR Site 34:

- Collect soil and groundwater data for site characterization and in support of a feasibility study (FS), if necessary
- Evaluate the physical setting, geology, hydrogeology, and ecology of IR Site 34
- Assess the nature and extent and fate and transport of those chemicals at the site demonstrating significant risk to human health or the environment
- Conduct background comparisons for soil and groundwater
- Conduct a Baseline Human Health Risk Assessment (HHRA) and Screening-Level Ecological Risk Assessment (SLERA).

This RI Report is divided into nine sections, as summarized below.

- Section 1.0, Introduction – identifies the purpose of the RI Report, outlines the organization of the report, and presents background information for IR Site 34.
- Section 2.0, Physical Setting – describes the climate, topography, geology, hydrogeology, groundwater use, surface water drainage system and tides, and ecological habitats of Alameda Point and IR Site 34. This section also presents the initial conceptual site model (CSM) and the identification of exposure units.
- Section 3.0, Investigation Approach and Scope – describes the methods and approaches for conducting the RI, including (1) establishing data quality objectives (DQO) and conducting data quality assessments; (2) conducting background comparisons; (3) evaluating the nature and extent of contamination; (4) performing fate and transport analyses; and (5) conducting the HHRA and the SLERA.
- Section 4.0, Nature and Extent of Contamination – summarizes the sample history, the results for each medium collected, and the chemicals exceeding comparison criteria at IR Site 34.
- Section 5.0, Fate and Transport of Chemicals in Soil and Groundwater at IR Site 34 – presents the evaluation of chemicals exceeding comparison criteria and migration pathways to determine the fate and transport of chemicals in soil and groundwater at IR Site 34.
- Section 6.0, Baseline Human Health Risk Assessment – summarizes the approach, receptors evaluated, and uncertainty analysis conducted as part of the HHRA; and presents the conclusions based on the HHRA results.
- Section 7.0, Screening-Level Ecological Risk Assessment – summarizes the characterization of ecology at IR Site 34, including the receptors evaluated and the chemicals of potential ecological concern (COPEC) based on the data. This section also describes the uncertainties associated with the SLERA and presents the conclusions based on the SLERA results.
- Section 8.0, Conclusions and Recommendations – describes the conclusions and recommendations for IR Site 34 based on the RI results.
- Section 9.0, References – lists the documents used to prepare this RI Report.

Figures and tables are provided at the end of the section of the text in which they are first mentioned. This RI Report also includes the following nine appendices, which contain supplemental information used to prepare this report and are presented after Section 9.0:

- Appendix A, Investigation Procedures and Field Methodology
- Appendix B, Soil Boring Logs
- Appendix C, Aquifer Testing
- Appendix D, Analytical Results for Soil Samples
- Appendix E, Analytical Results for Groundwater Samples
- Appendix F, Quality Control Summary Report
- Appendix G, Methods for Calculating Exposure Point Concentrations and Conducting Background Comparison of Soil and Groundwater
- Appendix H, Baseline Human Health Risk Assessment
- Appendix I, Screening-Level Ecological Risk Assessment
- Appendix J, Responses to Regulatory Agency Comments on the Draft Remedial Investigation Report

## **1.3 BACKGROUND**

This section summarizes the regulatory framework for the RI (see Section 1.3.1), briefly describes the location and history of Alameda Point (see Section 1.3.2), describes the history and previous operations at IR Site 34 (see Section 1.3.3); summarizes the previous investigations at IR Site 34 (see Section 1.3.4) and previous investigations of properties bordering IR Site 34 (see Section 1.3.5), and presents the future uses of the land at IR Site 34 (see Section 1.3.6).

### **1.3.1 Regulatory Framework**

In 1975, the U.S. Department of Defense (DoD) initiated a program to identify and investigate potential hazardous waste sites at military installations. The program was the result of increasing public and government concern over the potential impacts of past hazardous waste disposal methods. This program was expanded in 1980 as the DoD IR Program.

Concurrent with the formation of the IR Program, the U.S. Congress directed EPA to develop a comprehensive national program to manage past disposal sites. The basis for this program is the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA, or "Superfund") as amended in 1986 by the Superfund Amendments and Reauthorization Act.

CERCLA Section 120 was adopted by DoD in 1986 as the driver for Federal Facility Cleanup, which established the Navy as the lead agency and defined roles for EPA and state agencies. In 1988, DoD adopted EPA's terminology for the investigation and remediation of past hazardous waste disposal sites for use in its IR Program.

The Navy is responsible for environmental restoration at IR Site 34. The lead oversight agency is the EPA; however, the California Environmental Protection Agency's (Cal/EPA) Department of Toxic Substances Control (DTSC) and the San Francisco Regional Water Quality Control Board (Water Board) must concur with all of the property transfers. These regulatory agencies along with the Base Realignment and Closure (BRAC) Environmental Coordinator are responsible for the transfer of the base property and facilities to the community as expeditiously as possible and with a minimal effect on the local community.

Alameda Point was identified for closure in 1993. In April 1994, the City of Alameda signed a Joint Powers Agreement and established the Alameda Reuse and Redevelopment Authority (ARRA). The ARRA was recognized by the DoD as the responsible entity for submitting and completing the community reuse plan for Alameda Point. In 1997, the base was closed, and the Navy began the process of property transfer to the City of Alameda.

In July 1999, Alameda Point was identified as a National Priorities List site. Therefore, EPA and Navy RI protocols were followed while conducting the fieldwork and preparing this RI Report for IR Site 34. The RI/FS process includes evaluating the nature and extent of contamination, the human and ecological risk posed by the contamination, and options for clean up of the contamination.

Petroleum fuel sites and Resource Conservation and Recovery Act (RCRA) sites at Alameda Point are being investigated concurrently with the CERCLA investigations under the Navy's total petroleum hydrocarbons (TPH) and RCRA programs. As part of the Navy's TPH program, TPH contamination evaluations were conducted across Alameda Point. Fourteen Corrective Action Areas (CAA) and two fuel line CAAs were designated as a result of these evaluations. The CAA program for petroleum-affected areas at Alameda Point is overseen by the Water Board, in cooperation with the DTSC and EPA. Two TPH CAAs are present at IR Site 34, which are further described in Section 1.3.4.4.

### **1.3.2 Alameda Point Description and History**

Originally a peninsula, Alameda Island was detached from the mainland in 1876, when a channel was cut to link San Leandro Bay with the San Francisco Bay (also referred to as the Bay). The area encompassed by Alameda Point was historically a combination of submerged lands, tideland, and dry land. Alameda Point occupies the flattest portion of Alameda, reflecting its origins as diked bay lands and mudflats. Much of the land now occupied by Alameda Point was originally covered by the waters of the San Francisco Bay or tidal flats, but was gradually filled using hydraulically placed dredge spoils from the surrounding San Francisco Bay, Seaplane Lagoon, and Oakland Inner Harbor. The first documented filling of tidal and submerged land began some time during 1887. By 1927, the northern part of what later became Alameda Point

had been filled, primarily with dredge materials from U.S. Army Corps of Engineers projects associated with the Oakland Inner Harbor and other harbors throughout the East Bay (see Figure 1-1).

In 1887, two narrow-gauge railroads were constructed parallel to the Oakland Inner Harbor and extended to a pier and ferry terminal (known as the "Alameda Mole") on the northwestern tip of Alameda Point. Aerial photographs show the railroads crossed the area that is now designated IR Site 34. The Alameda Mole burned down in 1902, was rebuilt in 1903, and continued operation until 1939. The Alameda Mole was used primarily for passenger transport to the ferry terminal, but also was used for loading and unloading ships.

The filled land was partially occupied by the Alameda Airport, a City-owned facility, and Benton Field, a minor U.S. Army Air Corps facility. The U.S. Department of the Army (Army) acquired the Alameda Point site from the City of Alameda in 1930 and began construction activities in 1931. The Navy acquired title to the land from the Army in 1936 and began building the air station called NAS Alameda. NAS Alameda was commissioned on November 1, 1940. Its original primary mission was to provide facilities and support for fleet aviation activities. Following World War II, NAS Alameda served as a critical component to support Navy activities during the Korean War, the Vietnam War, and Operation Desert Storm (Kuwait). During its history, NAS Alameda housed approximately 60 military tenant commands for a combined military and civilian work force of over 18,000 personnel.

### **1.3.3 IR Site 34 Description and Operations**

IR Site 34 is located in the north-central portion of Alameda Point, adjacent to the Oakland Inner Harbor (see Figure 1-2). The boundaries of IR Site 34 were identified during the 2003 SI in which site risks were identified based on results of EBS samples (Bechtel Environmental, Inc. 2003). IR Site 34 is a 4.18-acre area that is a partially paved, relatively flat open space. IR Site 34 consists of EBS Parcels 4 and 18, a small unused portion of EBS Parcel 16, and an unnamed portion of land between the EBS parcels and the Oakland Inner Harbor. IR Site 34 was a Naval Air Rework Facility (NARF) used to maintain base equipment such as scaffolding and other apparatus. The site was used primarily for painting services, storage, wood and metal shop activities, and sandblasting activities. Numerous structures, including 12 buildings (330, 331, 343, 344, 472, 474, 475, 476, 477, 479, 510, and 604) and intervening open areas; seven aboveground storage tanks (AST) (330A, 330B, 344A, 344B, 344C, 344D, and 331); generator accumulation points (GAP) 78 and 79; 15 transformers (previously located in Buildings 330, 331, 343, 344, 472, 474, 475, 476, 477, and 479); and an aviation gasoline fuel line were present within IR Site 34. All buildings, ASTs, GAPs, transformers, and fuel lines were removed between 1996 and 2000, except for their concrete pads. Various pesticides were used for weed control throughout Alameda Point. Figure 1-3 shows the historical and existing site features at IR Site 34.

### **1.3.3.1 Historical Ownership and Operations**

The site history and descriptions of site physical features summarized below were developed based on review of the Phase 1 EBS Report (ERM-West 1994), Site 15 Removal Action Closeout Report (Tetra Tech EM Inc. [Tetra Tech] 1998), historical aerial photographs, and discussions with Navy staff who worked at the base in the 1990s.

IR Site 34 was once part of the San Francisco Bay along the Oakland Inner Harbor's southern border. In the 1920s, most of IR Site 34 was filled with estuary dredging material during construction of the Posey Tube, which is about 2 miles east of the site. In 1936, 68.47 acres along the northern boundary of the base (including IR Site 34) was transferred to the Navy from the Army.

No records exist indicating buildings were present at IR Site 34 prior to the Navy's operations at the site. The Navy constructed 12 buildings at IR Site 34 (see Figure 1-3). Table 1-1 summarizes the construction dates, activities, and investigation findings for each building. Based on a review of aerial photographs and discussion with Navy staff, all buildings and associated structures were removed between 1996 and 2000. Associated structures included seven ASTs, three designated RCRA sites, electrical transformers, and open space. A storm sewer line ran adjacent to the CERCLA boundary line located between Parcels 4 and 18 within IR Site 34. Another storm sewer extended approximately 40 feet onto IR Site 34 from its western border.

All activity at IR Site 34 ceased when the base closed in 1996. Based on the age of the buildings, lead-based paint was most likely used on all former buildings in IR Site 34 (mostly Parcels 4 and 18) and surrounding parcels. No activity occurred within the portion of EBS Parcel 16 that lies within IR Site 34 and the unnamed portion of land between the EBS parcels and the Oakland Inner Harbor (ERM-West 1994).

The southwest corner of IR Site 34 (listed as "Open Space 2" in Table 1-1) was used as a temporary storage and treatment area (TSTA) for soil excavated from IR Site 15 between 1995 and 1997 (Tetra Tech 1998b). The removal action was based on a cleanup level of 1 milligram per kilogram (mg/kg) for polychlorinated biphenyls (PCB) in soil. The TSTA was a bermed containment cell consisting of a double layer of 20-millimeter-thick high-density polyethylene over 4 to 6 inches of imported sand. The sand was used to provide positive slopes to the containment area to allow for collection of runoff water. The TSTA had a leachate collection system consisting of a leachate collection trench around the edges of the containment cell, a sump pump, a 5,000-gallon recovery tank, and a 21,000-gallon leachate storage tank. Contaminated soil was transported to the TSTA in November and December 1995. Soil was placed in three discrete stockpiles based on its chemical characteristics (for example, low concentrations of PCBs, high concentrations of PCBs, and high concentrations of lead). All stockpiles were covered with geotextile landfill cover material. Daily, weekly, and monthly inspections were performed during operation and maintenance of the TSTA.

In February 1996, a 30-mil-thick high-density polyethylene sheet was placed over the stockpiles to reduce infiltration of rainwater and contaminated leachate runoff. Leachate was pumped to recovery and storage tanks, analyzed, and then disposed of at an EPA-approved disposal facility. During September and October 1997, the stockpiled soil was characterized for disposal and transported to an EPA-approved landfill. After the removal of contaminated soil from the TSTA, samples were collected from the sand bed, underlying containment cell, and soil beneath the leachate recovery trench and analyzed for PCBs and lead. The sand bed was over-excavated and disposed of in a Class II disposal site.

### **1.3.3.2      *Adjacent Parcels***

The parcels adjacent to IR Site 34 include (counter-clockwise from the northwest) EBS Parcels 16, 17, 23H, 19, and 21 (see Figure 1-3). The adjacent parcels are briefly summarized below.

**EBS Parcel 16.** This parcel is approximately 6 acres in size and is located northwest of IR Site 34. Parcel 16 contains two buildings (375, tank truck loading stand, and 376, an electrical transformer house that housed five transformers) and three underground storage tanks (UST) (374P-1, 374-1, and 374-2).

UST 374-P-1 was removed in 1994, and further investigations were conducted in 1995 and 1997 to 2001. Analytical results reported all chemicals were below 1996 residential preliminary remediation goals (PRG), background concentrations, and TPH criteria; therefore, no further action was recommended (IT Corp. 1999).

USTs 374-1 and 374-2 were filled with concrete and closed in place in September 1997 (IT Corp. 1999). Soil and groundwater samples were collected near the USTs 374-1 and 374-2 during the EBS Phase 2A and 2B investigations. Concentrations of TPH and polycyclic aromatic hydrocarbons (PAH) were detected in soil and groundwater near the USTs. USTs 374-1 and 374-2 are part of Fuel Line CAA A, and will be investigated further as part of the CAA (IT Corp. 1999).

**EBS Parcel 17.** Parcel 17 is approximately 2 acres in size and is located directly west of IR Site 34. Parcel 17 formerly contained four buildings: 22, use unknown; 83, offices; 528, maintenance shop; and 597, welding, steel cutting, and tire shop. All four buildings were over 300 feet west of IR Site 34.

**EBS Parcel 23H.** Parcel 23H is approximately 71.5 acres in size and is located along the southern boundary of IR Site 34. There is no documented use of this site.

**EBS Parcel 19.** This parcel is 1 acre in size and located along the east boundary of IR Site 34. Parcel 19 formerly contained six buildings: 469, sewage pump station; 345, welding and general maintenance; 471, general maintenance including welding sandblasting and painting; 473, housed a large metal shear; 478, housed a large saw to support carpentry activity; and 479, hazardous flammable storage unit. Parcel 19 also formerly contained UST 473-1, located along

the southeastern border of the IR Site 34 boundary. No documentation was found on historical activities at Buildings P45, 291, and a former building located in the southern portion of Parcel 19. In general, the area was used to support ground maintenance activity associated with aircraft repair.

**EBS Parcel 21.** This parcel is 1.6 acres in size and is located northeast of IR Site 34. The parcel is roughly "L"-shaped, and its eastern border is adjacent to IR Site 15. Eighty percent of Parcel 21 is open space; 90 percent of which is paved with asphalt. It was used to support aircraft ground support equipment. Parcel 21 formerly contained four buildings: 28, a steel workshop; 240, a carpentry shop; 290, an electric shop; and 300, used for tool room, dry storage, and weight room.

### **1.3.4 Previous Investigations at IR Site 34**

The Navy conducted various investigations within IR Site 34 after it was used as a NARF. These previous investigations included the Phase 1 EBS investigation, TPH CAA investigations, the SI, and RI fieldwork. Results and conclusions and recommendations, if applicable, of each previous investigation are summarized in the following subsections.

#### **1.3.4.1 1994-1998 EBS Investigation**

The EBS program at Alameda Point began in 1993 under BRAC to assess the environmental conditions associated with each land parcel. Environmental conditions were assessed in accordance with RCRA, CERCLA, and the Community Environmental Response Facilitation Act regulations. The EBS program at Alameda Point was implemented in two phases: Phase 1, which included an assessment of all environmental effects associated with base operations for each parcel; and Phase 2, which was subdivided into phases 2A and 2B and consisted of collection of samples to evaluate the potential effects to soil and groundwater at Alameda Point. Phase 1 was conducted in 1994, and Phase 2 was conducted from 1994 to 1998. Each phase is briefly summarized below.

#### **Phase 1 EBS Investigation**

Phase 1 activities included site visits, brief employee interviews, and historical documentation about the various parcels (ERM-West 1994). The Navy conducted Phase 1 of their EBS investigation in 1994 to observe base operations and determine environmental conditions associated with each parcel at the base. The Phase 1 investigation provided the historical and operational information.

The findings of the Phase 1 investigation indicated that IR Site 34 was a NARF used to maintain base equipment such as scaffolding and other apparatus. The site was used primarily for painting services, storage, wood and metal shop activities, and sandblasting activities. IR Site 34 formerly contained several structures, including 12 buildings (331, 330, 343, 475, 344, 510, 474,

477, 604, 476, 479, and 472) and intervening open areas; seven ASTs (330A, 330B, 344A, 344B, 344C, 344D, and 331); GAPS 78 and 79; 15 transformers; and an aviation gasoline fuel line.

Detailed discussion of historical and operational information at IR Site 34 is presented in Section 1.3.3.1.

### **Phase 2A EBS Investigation**

During Phase 2A, surface soil (0.5 to 1 foot below ground surface [bgs]) samples were collected from four sampling locations (004-001-001, 004-001-002, 004-002-003, and 004-Z03-004) at Parcel 4 within IR Site 34. Samples contained stained or suspected TPH in surface soil. Samples were analyzed at a mobile laboratory, and one sample was analyzed at an off-site fixed laboratory. Samples were analyzed for metals, TPH as extractables, TPH as purgeables, and/or pesticides/PCBs. Analytical results indicated lead was the only metal detected at concentrations exceeding its 1996 EPA PRG or background concentration (IT Corp. 2001). Results for two samples indicated TPH as diesel and motor oil concentrations exceeded TPH comparison criteria. A confirmation sample was collected from location 004-001-002, and results indicated TPH as motor oil was below the comparison criteria. Aroclor-1260 was detected in one sample at concentrations exceeding the EPA 1996 PRG (IT Corp. 2001).

Parcel 18 had six target areas: (1) the ASTs (330A-B and 344A-D); (2) perimeters of Buildings 343 and 330; (3) Buildings 476, 477, and 479; (4) Open Space 2; (5) perimeter of Building 604; and (6) the area north of Building 510. Thirty surface soil samples, 3 duplicates, and 9 samples were collected from 30 locations sampling locations (018-001-001, 018-001-002, 018-001-005 through 018-001-008, 018-002-003, 018-002-004, 018-002-009 through 018-002-012, 018-003-013 through 018-003-019, 018-004-020 through 018-004-023, 018-005-024, 018-005-025, 018-006-026, 018-Z03-027 through 018-Z03-030). All samples were analyzed at an off-site fixed laboratory for the chemicals listed below.

- Samples from locations 018-001-001, 018-001-002, 018-001-005 through 018-001-008 were analyzed for TPH as extractables and TPH as purgeables.
- Samples from locations 018-002-003, 018-002-004, 018-002-009 through 018-002-012, and 018-006-026 were analyzed for metals.
- Samples from locations 018-003-013 through 018-003-019 were analyzed for volatile organic compounds (VOC).
- Samples from locations 018-004-020 through 018-004-023 were analyzed for metals, semivolatile organic compounds (SVOC), TPH as extractables, and TPH as purgeables.
- Samples from locations 018-005-024 and 018-005-025 were analyzed for metals, TPH as extractables, and TPH as purgeables.

- Samples from locations 018-Z03-027 through 018-Z03-030 were analyzed for pesticides and PCBs.

Analytical results indicated lead was present in soil in sampling locations north of Building 510 and east of Building 343 at concentrations exceeding the 1996 EPA PRG. Cadmium was detected collocated with the elevated lead in a surface sample, and an elevated concentration of arsenic was collocated with lead in a sample collected between 2.0 and 2.5 feet bgs. Aroclor-1254 and Aroclor-1260 were detected at concentrations exceeding the 1996 EPA PRGs in two soil samples collected from the southwest area of Parcel 18. TPH as diesel and TPH as motor oil exceeded the TPH comparison criteria in samples collected from AST-330B, AST 344A, AST-344B, and AST-344D. TPH constituents did not exceed the TPH comparison criteria in samples collected from ASTs 330A and 344C.

Additionally, a sediment sample was collected from storm drain catch basin AAA (AA-IT001-01). The sediment sample was analyzed for metals, VOCs, SVOCs, pesticides and organophosphorous pesticides, PCBs, TPH as extractables, and TPH as purgeables, TPH as oil and grease, herbicides, and organotins. Analytical results indicated sediment contained chromium, lead, and Aroclor-1260 at concentrations exceeding their respective 1996 EPA PRGs. This sediment was removed between 1996 and 1997 (Tetra Tech 2000b).

Based on these results, it was recommended that additional samples be collected at Parcels 4 and 18. More specifically, within the following locations at Parcels 4 and 18:

- Parcel 4: the southwest corner of Building 331 based on elevated concentrations of metals and TPH, former AST 331-1 based on elevated concentrations of metals and TPH, and within an unpaved and landscaped area based on an elevated concentration of Aroclor-1260.
- Parcel 18: between Buildings 330 and 343 because of widespread elevated concentrations of TPH; perimeters of Buildings 330 and 343 because of elevated concentrations of metals; Open Space 2 based on elevated concentrations of metals and TPH; perimeter of Building 604 based on elevated concentrations of TPH; and area north of Building 510 based on elevated concentrations of metals.

### **Phase 2B EBS Investigation**

In 1995, the Navy performed the Phase 2B EBS investigation at Parcels 4 and 18. Parcel 4 had three target areas: (1) the southwest corner of Building 331, (2) former AST 331, and (3) the northern border of Building 331. Based on the Phase 2A EBS sampling results, soil samples also were collected from one zone-specific area (northeast portion of Building 331) and analyzed for pesticides and PCBs. In total, 11 soil samples, including 1 duplicate sample, were collected from 5 sampling locations (004-003-008, 004-003-009, 004-Z03-005, 004-Z03-006, and 004-Z03-007). Two soil samples were collected from each sampling location: one surface soil sample and one deeper sample between 2.5 and 4.0 feet bgs. Soil samples collected from sampling locations 004-003-008 and 004-003-009 were analyzed for metals, SVOCs, TPH as

extractables, and TPH as purgeables; and soil samples collected from sampling locations 004-Z03-005 through 004-Z03-007 were analyzed for pesticides and PCBs. In addition, two groundwater samples were collected from locations 004-003-008 and 004-003-009 and analyzed for SVOCs and TPH as extractables.

Analytical results indicated several SVOCs exceeded the 1996 EPA PRGs in one sample from location 004-003-008 (IT Corp. 2001). TPH results for soil samples collected between 2.5 and 6 feet bgs were below laboratory detection limits, and TPH as diesel was detected at concentrations below the TPH screening criterion in groundwater. Pesticides and PCBs were not detected in any soil samples from Parcel 4.

The Phase 2B EBS investigation at Parcel 18 had five target areas: (1) between Buildings 330 and 343, (2) perimeters of Buildings 330 and 343, (3) Open Space 2, (4) perimeter of Building 604, and (5) area north of Building 510. In total, 17 soil samples, including 2 duplicate samples, were collected from 11 sampling locations (018-007-033 through 018-007-041 and 018-Z03-031 through 018-Z03-032). The samples (one surface soil sample and one deeper sample collected between 2.5 and 4.0 feet bgs) were collected from sampling location 018-007-035, 018-007-039, 018-Z03-031, and 018-Z03-032. Soil samples were collected between 2.5 and 4.5 feet bgs at the remaining sampling locations. Soil samples collected from locations 018-007-033, 018-007-035, 018-007-036, 018-007-038, 018-007-039, and 018-007-041 were analyzed for metals, SVOCs, TPH as extractables, and TPH as purgeables; samples from locations 018-007-034, 018-007-037, and 018-007-040 were analyzed for metals; and samples from locations 018-Z03-031 through 018-Z03-032 were analyzed for pesticides and PCBs.

All metals, except arsenic and lead, were detected at concentrations within the range of Alameda Point background or below the 1996 EPA PRGs. Arsenic and lead concentrations exceeded the 1996 EPA PRGs and background concentrations at one sampling location north of Building 510 (IT Corp. 2001). Benzo(a)pyrene [B(a)P] was the only detected SVOC that exceeded the 1996 EPA PRGs at location 018-007-035 (IT Corp. 2001). Pesticides and PCBs were not detected at concentrations exceeding laboratory reporting limits in four samples from two locations in the southwest portion of Parcel 18 (IT Corp. 2001). Analytical results indicated concentrations of TPH in one soil sample was less than the TPH comparison criteria (IT Corp. 2001).

Six groundwater samples, including one duplicate sample, were collected from locations 018-007-033, 018-007-035, 018-007-036, 018-007-039, and 018-007-041 within Parcel 18 and analyzed for SVOCs, TPH as extractables, and TPH as purgeables. No SVOCs were detected in the groundwater samples (IT Corp. 2001). Analytical results indicated concentrations of TPH in two groundwater samples were less than the TPH comparison criteria (IT Corp. 2001).

In addition, a groundwater sample was collected within the boundaries of IR Site 34 at location 473-002 during the removal of an off-site UST located on Parcel 19, east of IR Site 34. The groundwater sample collected from location 473-002 was analyzed for VOCs only. The groundwater sample collected from location 018-007-035 also was analyzed for metals. No VOCs were detected above detection limits, and all metals were detected at concentrations within the range of Alameda Point background or below the 1996 EPA PRGs (IT Corp. 2001).

Review of the Phase 2A and Phase 2B sampling data indicated the target areas in Parcels 4 and 18 have been sufficiently evaluated (IT Corp. 2001). The procedures and field methodology for this investigation is provided in Appendix A

#### **1.3.4.2 TPH CAA Investigations**

Naval aviation and Pacific Fleet operations conducted at Alameda Point involved the use of petroleum products. Tanks (aboveground and underground) and fuel lines were used to store and transport these products. After Alameda Point was included on the BRAC list in September 1993, the Navy was tasked to remove the tanks and begin cleanup activities to prepare the property for transfer to the City of Alameda. Evaluations of TPH contamination across Alameda Point have resulted in the designations of 14 CAAs and two fuel line CAAs. The CAA program for petroleum-affected areas at Alameda Point is overseen by the Water Board, in cooperation with the DTSC and EPA. Two TPH CAAs (14 and CAA A) are present at IR Site 34, as described below.

**CAA 14.** CAA 14 is located in the northwestern portion of Alameda Point along the southern shore of Oakland Inner Harbor. The CAA encompasses EBS Parcel 4. CAA 14 formerly contained Building 331 and associated AST 331. The nearest storm sewer line is orientated northeast to southwest 23 feet outside of the western boundary of the CAA. The same line includes one catch basin located about 30 feet west of Building 331, and empties into Oakland Inner Harbor at Outfall AA. CAA 14 was investigated during the Phase 1 EBS (ERM-West 1994) and the Phase 2 A and B EBS (IT Corp. 2001).

During the Phase 1 EBS investigation, the field crew observed TPH stained soil in two areas at CAA 14 south of Building 331 (location of former AST 331 and a former equipment pad). During the Phase 2 EBS investigation, the Navy collected four surface soil samples (004-001-002, 004-002-003, 004-003-008, and 004-003-009) south of former Building 331 (former location of AST 331 and a metal equipment pad). Two deeper soil samples also were collected at locations 004-003-008 and 004-003-009 between 2.5 and 6.0 feet bgs. Surface soil samples collected from locations 004-001-002 and 004-001-003 were analyzed for metals, TPH as extractables, and TPH as purgeables. Surface soil samples collected from locations 004-003-008 and 004-003-009 were analyzed for SVOCs, and the deeper soil samples collected from these locations also were analyzed for metals and TPH as extractables. In addition, groundwater samples were collected at sampling locations 004-003-008 and 004-003-009. Groundwater samples were analyzed for SVOCs and TPH as extractables.

Soil and groundwater sample results from the Phase 2 EBS indicated diesel fuel was released into shallow soil near former AST 331 (south of former Building 331) and motor oil was released to shallow soil under the metal equipment pad but does not extend to deeper soil or groundwater at concentrations greater than the TPH criteria (see Figures 1-4 and 1-5). Fuel line CAA 14 meets Water Board criteria for low-risk fuel site closure. As a result, the Navy requested no further action for CAA 14 from the Water Board (Tetra Tech 2004).

**Fuel Line CAA A.** Former Fuel Line CAA A was established because samples collected during removal of the fuel lines indicated jet fuel had been released to soil and groundwater, requiring an evaluation of potential risk to human and marine ecological receptors from TPH-related constituents. Prior to its removal, this fuel line crossed the southwestern portion of IR Site 34 and also crossed the storm drain lines associated with outfall BB at one location beyond the southwest of the border of IR Site 34. Between August and November 1997, a 240-foot segment of the fuel lines was removed by Allied Technology Group, Inc. IT Corp. removed the remaining 7,100 feet of fuel lines associated with Fuel Line CAA A in November and December 1998 (IT Corp. 1999).

In November and December 1998, the Navy collected 24 soil samples and 13 groundwater confirmation samples from the excavation during the removal of the fuel line. Only one soil and one groundwater sample (030-FLI-519 and 030-FLI-122, respectively) were collected from IR Site 34. In addition, two field screening samples were collected. Soil and groundwater samples were analyzed for benzene, toluene, ethylbenzene, xylenes, TPH as extractables, and TPH as purgeables. Results indicated TPH as gasoline exceeded the TPH comparison criteria in one of the field screening samples. Since reuse of this area does not include residential use, and TPH as gasoline was not detected in soil samples, corrective action is not warranted. Additionally, fuel line CAA A also met Water Board criteria for low-risk fuel site closure. No further action was recommended for CAA A (IT Corp. 2001).

#### **1.3.4.3 2003 Site Inspection**

The Navy conducted an SI on economic development conveyance (EDC)-3, which includes IR Site 34. EDC-3 consists of approximately 116 acres, of which 75 percent is open space. The Navy used this land for aircraft maintenance, runway facilities, storage and warehousing, and some maintenance shops. The SI was focused on further evaluation of the potential presence of PAHs in fill material in the EDC. During the SI, additional data were collected and combined with existing data from the EBS investigation to recalculate the risk to human health at EBS parcels within the EDC. Based on this information, the transfer parcels or portions of the transfer parcels were recommended for further action under the CERCLA or property transfer, whichever was appropriate (Bechtel Environmental, Inc. 2003).

Integration of the EBS data results indicated target risk levels were exceeded at Parcels 4 and 18 (which together comprise 99 percent of IR Site 34). Concentrations of Aroclor-1260 exceeded 1996 EPA PRGs at Parcel 4, and concentrations of arsenic exceeded the Alameda Point background concentration at Parcel 18 (Bechtel Environmental, Inc. 2003). Therefore, it was recommended that further action under CERCLA be taken at these two EBS parcels within IR Site 34.

#### **1.3.4.4 2006-2007 RI Field Work**

Based on the results of previous investigations and the identified data gaps at IR Site 34 the Navy decided that an RI was necessary. Fieldwork for the RI was conducted from February 2006 through March 2007 (SulTech 2006). The fieldwork for the RI was designed to address the

following types of data gaps: (1) need for further delineation of one or more chemicals that exceeded 1996 EPA PRGs; (2) need to fully investigate potential sources of contamination (such as the fence line, sandblasting areas, GAP sites, and the storm drain corridors); and (3) need to provide overall coverage of the entire site for the full list of chemicals of potential concern (COPC) for IR Site 34. The fieldwork consisted of two separate mobilizations, which are summarized below.

### **Field Mobilization 1**

During the first mobilization, the following types of samples were collected: (1) modified grid samples, (2) fence line PCB samples, (3) hotspot samples, (4) paint waste samples, (5) off-site samples at adjacent parcels, and (6) groundwater samples. The purpose of the first mobilization was to close the following data gaps:

1. Collect data from sampling locations previously lacking data for one or more chemicals
2. Determine the extent of soil containing metals and PCBs at concentrations exceeding PRGs
3. Collect a sufficient number of samples near former GAPs and storm sewers
4. Adequately define areas where chemicals were present above PRGs for the purposes of estimating potential risks to human and ecological receptors
5. Collect soil samples below the northern and western fence lines, where PCB-containing oil may have been applied for weed control
6. Evaluate whether paint wastes are present around buildings where sandblasting activities occurred
7. Evaluate shallow and deep soil exposure pathways

Thirty-eight modified grid soil samples (designated as DP01, DP02, and so forth) were collected from 14 sampling locations (DP01, DP02, DP05, DP06, DP07, DP08, DP10, DP12, DP13, and DP15 through DP19). Surface soil (0 to 1 foot bgs) and deeper soil (1.5 and 2.0 feet bgs) samples were collected from all sampling locations. Subsurface soil samples also were collected at 7.0 feet bgs (above the groundwater interface) from sampling locations DP05 through DP08, DP10, DP12, DP13, DP15, and DP16 to determine the vertical boundaries of chemicals in soil (SulTech 2006). Surface soil and deeper soil samples were analyzed for metals, PAHs, pesticides, and PCBs. The subsurface soil samples were analyzed for metals, VOCs, SVOCs (including PAHs), pesticides, PCBs, TPH as extractables, and TPH as purgeables.

Nineteen fence line surface soil samples were collected from 13 sampling locations (FS1 through FS5, FS5A, FS6, FS7, FS7A, FS8 through FS10, and FS10A). Deeper soil samples were also

collected between 1.5 and 2 feet bgs at six sampling locations (FS10, FS10A, FS5, FS5A, FS7, and FS7A). The fence line soil samples were analyzed for PCBs.

Thirty confirmation surface soil samples were collected from 20 sampling locations (HS1A, HS1E, HS1N, HS1W, HS2A, HS2W, HS3A, HS3E, HS3S, HS3SA, HS3W, HS4E, HS4W, HS5E, HS5S, HS6N, HS6S-5W, HS7N, HS7S, and HS7W). In addition, subsurface samples were collected between 1.0 and 4.0 feet bgs from 10 sampling locations (HS1N, HS1W, HS2W, HS3A, HS3E, HS3W, HS5E, HS6S-5W, HS7N, and HS7W). Four borings were collected where metals exceeded 1996 EPA PRGs during previous sampling events. The soil samples were analyzed for a combination of or all of the following chemicals: metals (including chromium), pesticides, and PCBs. Please see Table 1-2 for the corresponding analytical group for each sample.

Thirty-three paint waste soil samples were collected from 24 sampling locations (PW-1 through PW-18, PW1A, PW4A, PW7A, PW9-10-15A, PW9-6A, and PW16-17-18A). A minimum of one surface soil (0 to 0.5 feet bgs), one deeper surface soil (1.0 to 1.5 feet bgs), or one subsurface soil (2.0 to 2.5 feet bgs) sample was collected at each location. Surface and subsurface samples were collected from five sampling locations (PW6, PW9, PW14, PW15, and PW4A), and samples from all three depth intervals were collected from two sampling locations (PW10 and PW7). Soil samples were analyzed for a combination of or all of the following chemicals: metals and PCBs. Please see Table 1-2 for the corresponding analytical group for each sample.

Four off-site soil samples were collected. Two surface soil samples (0 to 0.5 foot bgs) and two deeper surface soil samples (1.0 to 1.5 feet bgs) were collected from two sampling locations (OS 1 and OS 2). These soil samples were analyzed for pesticides and PCBs.

Groundwater samples were collected from 19 sampling locations (DP01 through DP19), and 1 duplicate sample was collected from location DP16. Groundwater samples were analyzed for metals, VOCs, SVOCs (including PAHs), pesticides, PCBs, and TPH.

## **Field Mobilization 2**

During the second mobilization, the following activities were performed: (1) installation and development of four shallow and one deep monitoring wells, (2) collection of soil samples during each well installation, (3) aquifer testing, and (4) collection of groundwater samples. The purpose of the second mobilization was to obtain more data on potential migration of chemicals to groundwater and to clarify some of the analytical results from the first mobilization of the RI fieldwork.

As concentrations of chemicals in groundwater collected during the first mobilization exceeded the comparison criteria presented in the RI work plan (Sultech 2006), groundwater monitoring wells (MW-20 through MW-24) were installed during the second mobilization to monitor conditions at the site. Two monitoring wells were installed down gradient of the apparent source of groundwater contamination near the Oakland Inner Harbor, one shallow well (MW-23) and

one deeper well (MW-24) (see Figure 1-5). One well was installed near the source of the plume (MW-21), and the remaining two monitoring wells were installed to monitor the lateral limits of chemicals in groundwater to the south of the plume and the site (MW-22 and MW-20).

Eight soil samples were collected during the installation of five groundwater monitoring wells (MW-20 through MW-24). Two surface soil (0 to 1.0 foot bgs) samples were collected from wells MW-21, MW-22, and MW-24 and subsurface soil (1.0 to 4.0 feet bgs) samples were collected from wells MW-20, MW-21, MW-22, and MW-24. Only one soil sample was collected from MW-23 (105-S34-171) at a depth of 0.5 to 2.0 feet bgs because the deeper soil was saturated. Soil samples were analyzed for metals, VOCs, SVOCs (including PAHs), pesticides, PCBs, TPH as extractables, TPH as purgeables, and herbicides.

In July 2006, aquifer tests were conducted at one shallow well (MW-20) and one deep monitoring well (MW-24). The aquifer tests consisted of slug withdrawal testing or "rising head" tests. A solid slug of known volume was rapidly withdrawn from the well, and water levels were monitored using an electronic probe that was placed inside the well. Data from the slug test were analyzed using the methods of Bouwer and Rice (1976) for unconfined aquifers. In March 2007, an additional aquifer test was conducted on monitoring well (MW-24). The data and results from these slug tests are presented in Appendix C.

Two rounds of groundwater sampling were conducted. The first round of groundwater sampling was conducted in July 2006, and the second round of groundwater sampling was conducted in March 2007. The groundwater samples were analyzed for metals, VOCs, SVOCs (including PAHs), low-level pesticides, PCBs, TPH as extractables, and TPH as purgeables, and total dissolved solids (TDS).

### **Deviations from the RI Work Plan**

Several deviations from the RI work plan (Sultech 2006) occurred during the field investigations as a result of field conditions and are specified below.

- Pavement was encountered at some fence line locations (FSx); therefore, samples were collected at alternate locations approximately 10 feet from the fence line. Alternate locations were designated with an "A" in the location ID (FSxA).
- Sample location FS4A met refusal at 1-foot bgs due to rock/cobbles/boulder; therefore, only a surface sample was collected.
- Sample location FS6 was obstructed by vegetation and wooden forms along the edge of the former building; therefore, samples were collected from the west side of the fence.
- Sample location FS9 met refusal at 8 inches bgs; no deeper samples were collected.
- Sample location PW2 met groundwater at 7 inches bgs.

- Samples were only collected at locations PW10 and PW11 at 2 to 4 inches bgs due to bobcat auger malfunctions.

### **1.3.5 Previous Investigations at Adjacent Parcels**

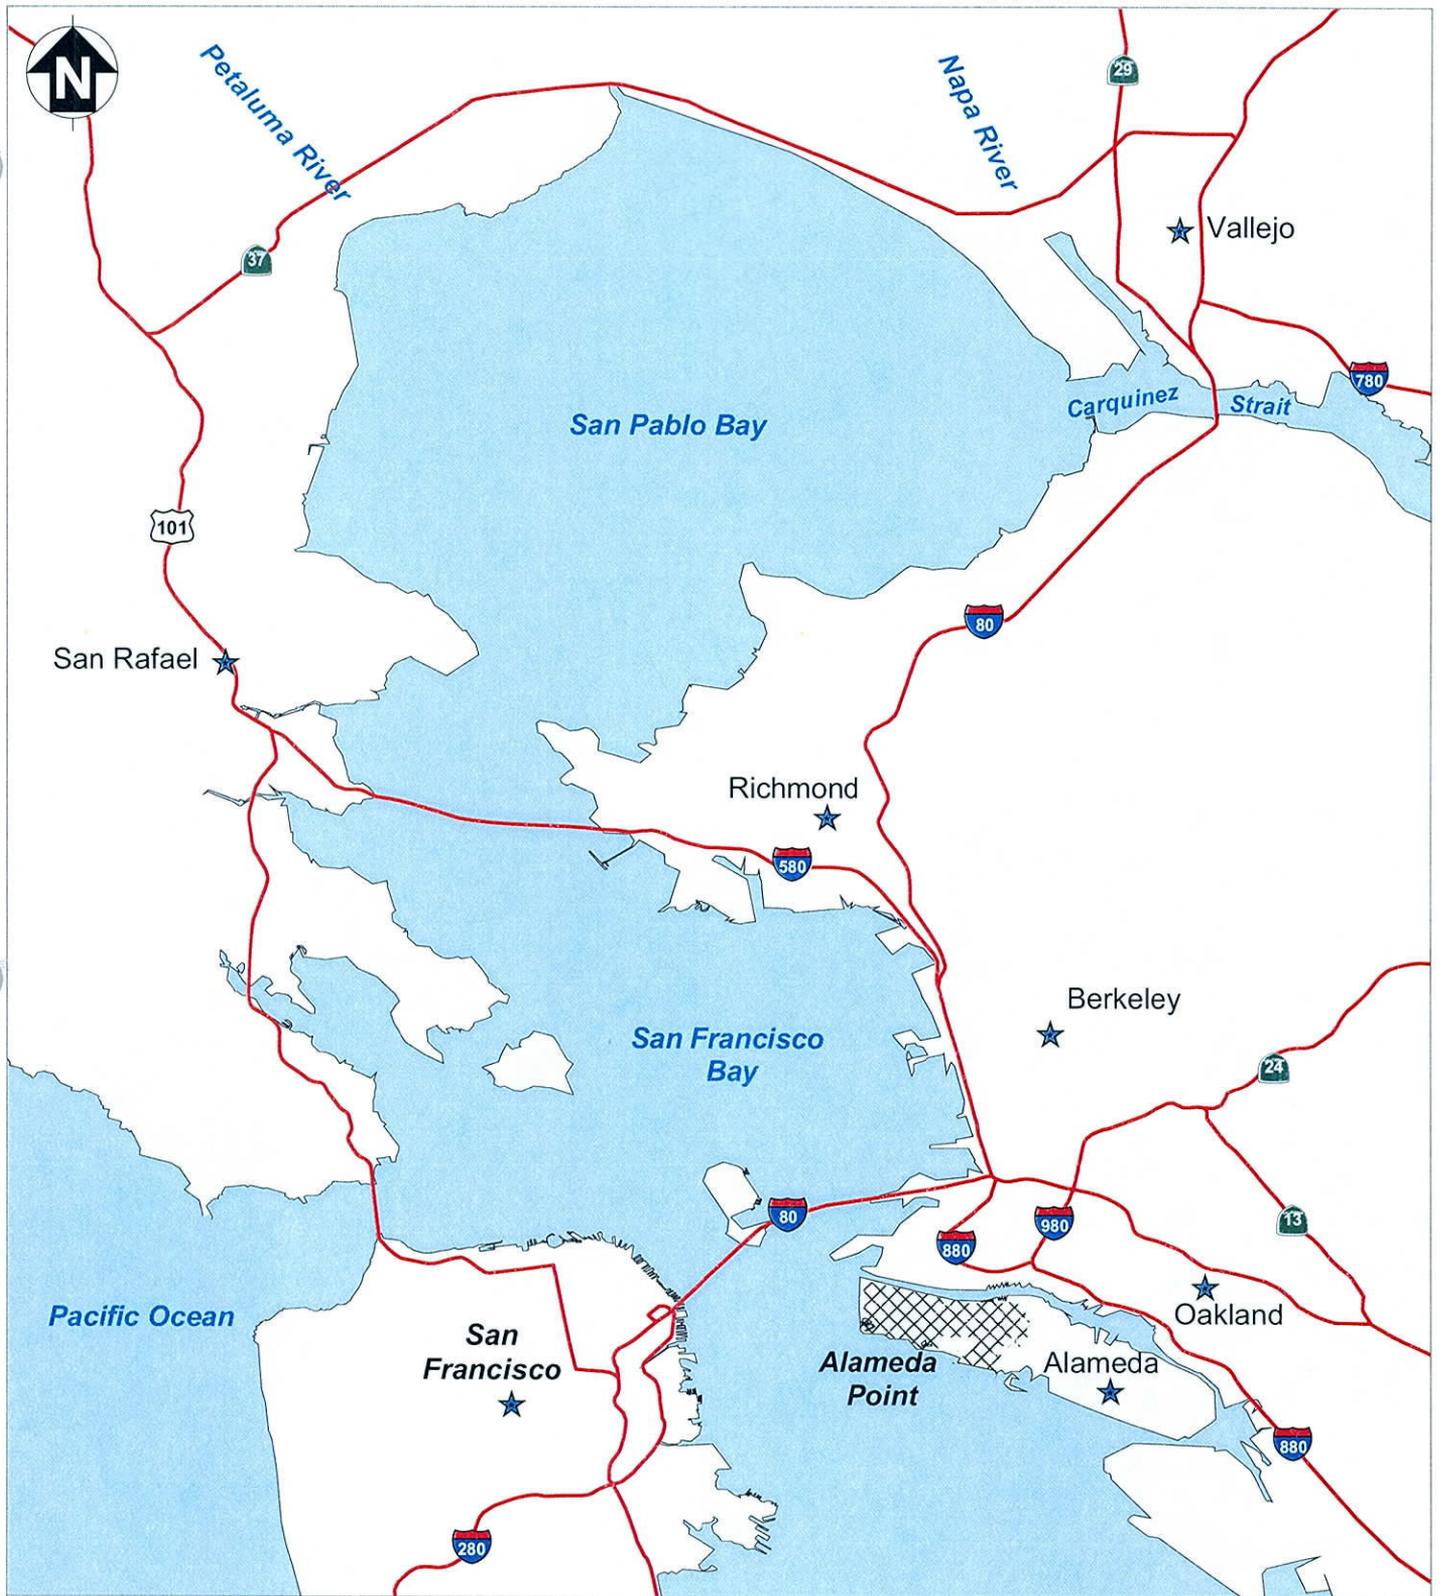

Investigations at the parcels adjacent to IR Site 34 included the EBS investigation (ERM-West 1994; IT Corp. 2001), TPH investigations of the pipeline (IT Corp. 1999), and the SI for Parcel 23H (Bechtel Environmental, Inc. 2003). The EBS investigation included Parcels 16, 17, 19, 21, and 23H. Results of the EBS sampling and UST removals indicated PCB contamination in soil at Parcel 16 has a potential to affect IR Site 34. The results of the previous investigations also indicated Parcels 17, 19, 21, and 23H have a low potential to affect IR Site 34.

### **1.3.6 Future Use**

IR Site 34 is considered part of the Northwest Territories. The Northwest Territories are designated as Public Open Space and Parks (City of Alameda 2003). Future use of IR Site 34 is designated as part of a golf course area. In addition, Site 34 has been identified as a tideland trust area that is subject to the limitations expressed in the Coastal Zone Management Act, including a restriction on residential use.

**TABLE 1-1: SUMMARY OF HISTORICAL USES, INVESTIGATIONS, AND FINDINGS FOR IR SITE 34 BUILDINGS**  
 Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Building/ Structure	Construction Date	Building Area (ft <sup>2</sup> )	Current Status (year)	Activity/ Associated Feature	Field Observations
330	1948	4,000	Demolished (1996-2001)	Metal working, carpentry, and storage of equipment salvaged from other buildings, ASTs 330A and 330B, and one transformer	Two diesel ASTs <sup>1</sup> (330A and 330B) were observed at the northwest and the southeast corners of Building 330. Two areas of heavy oil staining were observed near the location of the diesel ASTs. A stained concrete slab was observed where a diesel heater used to be located adjacent to Building 330. TPH was detected above the comparison criteria. Stains also were observed throughout the operations area of the building.
331	1948	4,000	Demolished (1996-2000)	NARF woodworking, AST 331 and one transformer	Staining was observed on a metal pad adjacent to the southwest side of the building, and heavily stained soil was observed around the AST area. Metals, PAHs, and PCBs were detected above 1996 EPA PRGs. TPH was detected above the comparison criteria. Building 331 was designated as a CAA because of a fuel releases associated with the AST.
343	1949	2,000	Demolished (1996-2000)	Sandblasting shop, storage of equipment and one transformer	Stored sandblasting grit was observed on the floor, and sandblasting equipment was stored in the building. The floor was rusted because of saltwater intrusions into the building.
344	1950	4,400	Demolished (1996-2000)	Sheet metal fabrication, lubricant use, three diesel ASTs, and one transformer	Three ASTs <sup>2</sup> (344B through 344D) were observed at Building 344. An empty flammable storage cabinet was observed, and 60 percent of the floor in the building was stained from lubricants. Staining was observed around all of the ASTs. The northeastern tank was surrounded by 15 by 30 ft <sup>2</sup> of stained soil. TPH was detected above the comparison criteria.

**TABLE 1-1: SUMMARY OF HISTORICAL USES, INVESTIGATIONS, AND FINDINGS FOR IR SITE 34 BUILDINGS (CONTINUED)**

Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Building/ Structure	Construction Date	Building Area (ft <sup>2</sup> )	Current Status (year)	Activity/ Associated Feature	Field Observations
472	1946	800	Demolished (unknown)	Metal and lumber storage, one transformer	No observations were made about conditions of the building during field activities for the EBS report.
474	1950	810	Demolished (1996-2000)	Sheet metal fabrication, lubricant use, and six transformers	No observations were made about conditions of the building during field activities for the EBS report.
475	1952	1,750	Demolished (1996-2000)	Bead blasting activities, one AST, and one transformer	Staining was observed below the AST <sup>2</sup> (344A). Chemicals that may have been used in the building included abrasive blast media and paint removed during blasting activities. TPH was detected above the comparison criteria.
476	1953	750	Demolished (1996-2000)	Paint storage and one transformer	Paint stains were observed on the floor of the building, and a rust-colored material was observed in the dirt in front of the building. PAHs were detected above the 1996 EPA PRGs in one surface sample.
477	1952	1,000	Demolished (1996-2000)	Painting activities— Paint Booth and one transformer	Paint booths contained water and paint residue and paints, solvents, and paint waste were stored in the building. TPH was detected above the comparison criteria.
479	1951	216	Demolished (1996-2000)	Storage area for hazardous wastes, RCRA GAP 78 and one transformer	Staining, mottling, and corrosion were observed on the concrete.

**TABLE 1-1: SUMMARY OF HISTORICAL USES, INVESTIGATIONS, AND FINDINGS FOR IR SITE 34 BUILDINGS (CONTINUED)**

Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Building/ Structure	Construction Date	Building Area (ft <sup>2</sup> )	Current Status (year)	Activity/ Associated Feature	Field Observations
510	1967	3,700	Demolished (1996-2000)	Storage of wood and metal	Stains were observed on the floor of the building and in the shed area. Additionally, sandblasting grit was present in the shed area and along the exterior of the building. Arsenic and lead were detected above the 1996 EPA PRGs and background concentrations (north side of the building).
604	1952	800	Demolished (1996-2000)	Paint removal; two air compressors in the building and one compressor outside the building	Chemicals included petroleum oils associated with the air compressors, an empty kerosene drum located outside of the building, and red-colored sand from garnet blast media.
SWMU (AST 331-1)	1948	NA	Removed (1996-2000)	Storage of diesel fuel	Soil around the AST was heavily stained.
NADEP GAP 78	NA	216	Demolished (1996-2000)	GAP	GAP 78 occupied the entire space of Building 479. An accumulation of drums and cans of paint were observed.
NADEP GAP 79	NA	NA	Demolished (1996-2000)	Storage building	This GAP was located south of Building 472. Sandblasting grit was observed.
UST/ Fuel Lines	NA	NA	Removed (1998)	Transporting fuel for base operations	Breaks in the pipeline were observed before the removal in 1998. TPH-motor oil detected in soil and TPH-gasoline detected in groundwater were below TPH comparison criteria.
Transformers	NA	NA	Removed (1996-2000)	Transformer	Fifteen transformers were previously located at IR Site 34. No stains were associated with the transformers. No transformers remain at IR Site 34.

**TABLE 1-1: SUMMARY OF HISTORICAL USES, INVESTIGATIONS, AND FINDINGS FOR IR SITE 34 BUILDINGS (CONTINUED)**

## **2.0 PHYSICAL SETTING**

Alameda Point is located at the west end of Alameda Island and is bordered by the Oakland Inner Harbor (north and east sides), and San Francisco Bay (west and south sides) (see Figure 1-1). No naturally occurring surface streams or ponds are present at Alameda Point, so precipitation either returns to the atmosphere by evapotranspiration, runs off in the storm drain system that discharges to San Francisco Bay, or infiltrates to groundwater (Tetra Tech 1998b). Physical features at Alameda Point include streets, buildings (including hangars), runways, fuel lines and utility lines, ASTs, and USTs. Some of the fuel lines, ASTs, and USTs have been removed, while others have been closed.

### **2.1 CLIMATE**

The San Francisco Bay Area experiences a maritime climate with mild summer and winter temperatures. The varied topography of the San Francisco Bay Area affects climactic conditions of subareas within the San Francisco Bay region. Heavy fogs occur on an average of 21 days per year, and rainfall occurs primarily during the months of October through April; Alameda Point averages approximately 18 inches of rainfall a year (Air Traffic Control, NAS Alameda 1992). Prevailing winds usually blow from west to east in the Bay Area.

### **2.2 TOPOGRAPHY**

The Bay Area is characterized by its varied topography. As indicated above in Section 2.1, climactic conditions vary considerably throughout the San Francisco Bay region as a result of the varied topography. Alameda Point is located at the base of a gently westward-sloping plain that extends from the Oakland-Berkeley Hills in the east to the shore of the San Francisco Bay on the west. Alameda Point is characterized by a low topographic profile. The surface elevations vary from mean sea level (msl) to approximately 30 feet above msl. IR Site 34 is located in the northwestern portion of Alameda Point. The area is flat with ground surface elevations from approximately 9 to 10 feet above msl.

### **2.3 GEOLOGY**

This section provides an overview of the geology in the region (see Section 2.3.1) and at IR Site 34 (see Section 2.3.2). The description of the regional geology and the IR Site 34 geology is based on the work of Trask and Ralston (1951), Treasher (1963), Radbruch (1957, 1969), Atwater and others (1977), Atwater (1979), Helley and others (1979), Rogers and Figuers (1991), Sloan (1990, 1992), Figuers (1998), and SulTech (2006). Boring logs also were reviewed to provide more information about the geology of IR Site 34 (see Appendix B).

#### **2.3.1 Regional Geology**

Alameda Point occupies a depression between two uplifted areas: the Berkeley Hills on the east and the San Bruno and other mountains on the San Francisco Peninsula to the west. The

depression and uplifted areas are formed by two subparallel, active faults: the San Andreas (western) and the Hayward (eastern) Faults.

In the subsurface, the San Francisco Bay is approximately coincident with the axis of the bedrock trough, which was formed 1 million to 500,000 years ago by crustal movements associated with two active faults. During interglacial periods, the Pacific Ocean entered the basin, which resulted in wide deposition of estuarine muds (Figuers 1998). Additionally, the trough would fill with sand and silt, and gravel eroded from the surrounding hills through a sequence of coalescing alluvial fans. A compound alluvial fan (bajada) was formed.

Today, regional geologic conditions in the Bay Area reflect this depositional history. Alameda and the surrounding San Francisco Bay are underlain by 400 to 500 feet of unconsolidated sediments that overlie the metamorphosed sandstone, siltstone, shale, greywacke, and igneous bedrock, which forms the Franciscan Formation (Bechtel Environmental, Inc. 2003).

Surface and near-surface soil at Alameda Point consists of artificial fill emplaced during historical filling of the tidal marshlands and the subtidal area of San Francisco Bay during site development. The fill material consists of sediments that were dredged from the San Francisco Bay and Oakland Inner Harbor and is characterized by sands, clays, and silts dredged from the tidal flats in the region (Bechtel Environmental, Inc. 2003). The unconsolidated sediments that lie beneath the artificial fill consist of the following units, from oldest to youngest: (1) Franciscan Formation, (2) the Alameda Formation, (3) the lower unit of the San Antonio Formation (Yerba Buena Mud), (4) the upper unit of the San Antonio Formation, (5) the Merritt Sand Formation, and (6) the Bay Sediment Unit (BSU) (see Figure 2-1).

A layer with high organic content, called the "marsh crust," typically marks the top of the BSU throughout the eastern portion of Alameda Point. The marsh crust is a layer of contaminated sediment that was formed by the discharge of petroleum waste from two gas plants and an oil refinery. This waste migrated over much of the surface of the surrounding marshlands and was deposited through tidal actions under what would later become the Alameda Annex and the eastern portion of Alameda Point. The marsh crust has been identified south and east of IR Site 34, but has not been identified beneath IR Site 34.

### **2.3.2 IR Site 34 Geology**

Artificial fill at IR Site 34 extended from ground surface to depth ranging from 6 feet to 14 feet or more bgs, and overlies the BSU. The fill material is primarily poorly graded, fine- to medium-grained sand, with interbedded clay and sandy clay. The BSU is found from about 6 to 50 feet bgs. The Merritt Sand Formation was present in one soil boring located in the central portion of IR Site 34 at 30 feet bgs. In the northern portion of IR Site 34, the Upper San Antonio Formation ranged from 13 feet to 82 feet bgs, with the Lower San Antonio Formation ranging from 82 feet to 135 feet bgs (Subsurface Consultants, Inc. [SCI] 1998). In the northern portion of IR Site 34 the Alameda Foundation was encountered at 135 feet bgs (SCI 1998; SCI and Todd Engineers 1998). Soil boring depths within the central and southern portions IR Site 34 did not exceed 44 feet bgs; therefore, deeper formation information is not available. Figures 2-2 and 2-3

show the north to south cross section of IR Site 34 and the east to west cross section of IR Site 34, respectively. Available boring logs for IR Site 34 are presented in Appendix B.

## **2.4 HYDROGEOLOGY**

This section describes the regional hydrogeology and the hydrogeology of Alameda Point and IR Site 34.

### **2.4.1 Regional Hydrogeology**

Alameda Point is near the center of the San Francisco Basin. The lower half of the San Francisco Basin is filled with continental units; the upper part of the San Francisco Basin is filled with an alternating sequence of marine and continental units. The San Francisco Basin is an elongated, sediment-filled trough oriented in a northwest-southeast direction, parallel to the trend of regional geologic structural features. Regional aquifers identified in the San Francisco Basin correlate with the continental/alluvial fan deposits. Regional aquitards correspond to estuarine mud deposits such as the Younger Bay Mud and the Yerba Buena Mud. Aquifers in the eastern San Francisco Bay extend east to the Hayward Fault, where they merge into a vertically continuous, coarse-grained alluvial fan sequence. The aquifers are nonhomogeneous, with the particle size of materials generally becoming smaller from east to west. The aquifers can exhibit significant lateral and vertical variations, which reflect changes in the natural localized depositional environments (SulTech 2006).

The three primary aquifers in the east Bay Area (upper to lower) are: (1) Newark, (2) Centerville, and (3) Fremont. The Newark Aquifer is 100 to 150 feet thick in the region and is contained within sediments of the San Antonio and Merritt Sand Formations. The Newark Aquifer is confined in the areas where the Merritt Sand is overlain by the Younger Bay Mud. The Irvington Aquitard confines the Newark Aquifer from below. The Irvington Aquitard is contained in fine-grained sediments of the Yerba Buena Mud. The underlying Centerville Aquifer is about 100 ft thick and extends to depths of about 220 ft (Maslonkowski 1988). Fremont aquifer is a generic name for discontinuous sand and gravel deposits between 240 and 400 ft below land surface.

The following section describes the hydrostratigraphy or system of aquifers and intervening aquitards underlying Alameda Point and IR Site 34. The water-bearing units encountered at Alameda Point have been named based on their sequence in the subsurface; the aquitards are named based on the formation they are in. The local hydrostratigraphic units at Alameda Point correlate with regional hydrostratigraphic units, as shown in parentheses in the following text.

### **2.4.2 Alameda Point and IR Site 34 Hydrogeology**

Five local hydrostratigraphic units are identified at Alameda Point. Water-bearing units include the first water-bearing zone (FWBZ) and the second water-bearing zone (SWBZ) (confined Newark Aquifer). The FWBZ and the SWBZ are separated by the BSU (Newark Aquitard). The

occurrence of the SWBZ depends on the presence of the BSU, which acts as an aquitard separating the FWBZ and the SWBZ. The water-bearing units are underlain by the Yerba Buena Aquitard (Irvington Aquitard), which is underlain by the Alameda aquifer (the installation equivalent of the regional Centerville aquifer). However, beneath Site 34 the Alameda aquifer is deeper than 200 feet bgs and is overlain by approximately 175 feet thick aquitard. No data from Site 34 are available for this aquifer, so it will not be discussed further.

The FWBZ is an unconfined aquifer that occurs within the uppermost permeable units at Alameda Point, primarily the artificial fill materials, if present, or the Merritt Sand and the Upper San Antonio Formation in areas where the artificial fill and BSU are absent. Groundwater in most of the FWBZ at Alameda Point is fresh, but may be brackish (slightly saline) in areas near the shoreline. The depth to groundwater of the FWBZ ranges from 3 to 8 feet bgs across most of the installation. During drilling at Site 34, the groundwater was encountered at 2 to 6.5 feet bgs.

The SWBZ is a semiconfined and confined aquifer that occurs within the Merritt Sand and the Upper San Antonio Formation. The SWBZ is found only in portions of the installation where the overlying BSU is both present and consists of low permeability materials, such that it acts as a confining unit for the SWBZ. The SWBZ extends to the top of the Yerba Buena Mud, which functions as a confining unit below the SWBZ. Groundwater in SWBZ at Alameda Point is brackish to saline. At Site 34, the depth to the SWBZ ranges from approximately 30 to 50 feet bgs (see Figures 2-2 and 2-3).

Groundwater in both the FWBZ and the SWBZ under most of Alameda Point generally flows in a radial pattern toward the San Francisco Bay, the Oakland Inner Harbor, and the Seaplane Lagoon (see Figure 2-4). Groundwater flow directions vary through the year as a result of seasonal changes in precipitation rates and diurnal variations related to tidal cycles.

At IR Site 34, limited groundwater measurements from the four permanent monitoring wells screened in the FWBZ (see Tables 2-1 and 2-2) indicated that groundwater generally flows from south to north of the site toward the Oakland Inner Harbor at a gradient of up to 0.0015 (see Figure 2-5). The shallow unconfined aquifer in the FWBZ is composed primarily of fine, artificially deposited, estuarine sand fill with hydraulic conductivity characteristic of silty sands. Only one permanent monitoring well at Site 34 is screened in the SWBZ, so the site-specific data are insufficient for the determination of the groundwater flow direction and hydraulic gradient. However, based on the basewide map (see Figure 2-4), the groundwater flow direction and hydraulic gradient for the SWBZ at Site 34 are expected to be similar to those of the FWBZ.

The hydraulic conductivity of the FWBZ and SWBZ at IR Site 34 was evaluated through slug tests at monitoring wells MW-20 and MW-24, respectively. The results of the slug test were assessed using the rising head method of Bouwer and Rice. The average hydraulic conductivity for FWBZ was estimated at 22.3 feet per day [ft/day] (well MW-20). The average hydraulic conductivity and the storage coefficient value for the SWBZ are 0.052 and 0.002 ft/day, respectively (well MW-24). A more detailed discussion of the slug test results can be found in Appendix C.

The estimated hydraulic conductivity value for the FWBZ appears higher than expected for the logged lithology (fine sand) within the screened interval (see boring log for well MW-20 in Appendix B). Based on the estimated hydraulic conductivity value and hydraulic gradient and assuming a typical value of effective porosity for sands of 0.25, the calculated groundwater flow velocity in the FWBZ is approximately 49 feet per year. The estimated hydraulic conductivity value for the SWBZ appears to represent primarily the silty clay logged within the screened interval (see boring log for well MW-24 in Appendix B). The more permeable portion of the SWBZ is expected to have a much higher hydraulic conductivity. Although the data is insufficient to calculate the groundwater flow velocity for the SWBZ at Site 34, the velocity is expected to be comparable to that estimated for the FWBZ.

## **2.5 GROUNDWATER USE AND POTENTIAL BENEFICIAL USES**

Groundwater beneath the central portions of Alameda Point (including IR Site 34) is not currently used for drinking water, irrigation, or industrial supply. Drinking water is supplied to Alameda Point by the East Bay Municipal Utilities District.

Other potential beneficial uses of groundwater include industrial supply and agricultural use (crop irrigation or livestock watering). However, a beneficial use evaluation conducted for the purposes of CERCLA cleanup decisions determined that groundwater in the western portion of Alameda Point (including IR Site 34) is unlikely to be used as a potential drinking water source, or for watering livestock, based on proposed land uses (Tetra Tech 2000a). High concentrations of TDS in groundwater (or the likelihood of saltwater intrusion if any significant pumping takes place) would require pretreatment, which would not be economical. Within the western region of Alameda Point, which includes IR Site 34, no water supply wells exist within or downgradient of groundwater contamination. In addition, groundwater beneath IR Site 34 has little potential as a source of municipal or domestic water supply based upon the discussion below.

According to the Basin Plan for the San Francisco Bay (Water Board 1995) and the East Bay Plain Groundwater Basin Beneficial Use Evaluation Report (Water Board 1999), groundwater at Alameda Point has the following existing or potential beneficial uses:

1. Agricultural water supply
2. Industrial service and process supply
3. Freshwater replenishment to surface water
4. Municipal and domestic water supply

However, in 2000, the Water Board adopted groundwater basin plan amendments (Water Board Res. 00-024) that redesignated the municipal supply beneficial use for portions of Alameda Point, including IR Site 34. These amendments are still subject to approval by Cal/EPA's SWRCB and the State Office of Administrative Law. At this time, SWRCB staff has not yet determined when these amendments will be considered. However, in a letter dated July 21,

2003, the Navy received concurrence from the Water Board that groundwater meets the municipal and domestic water supply designation exemption criteria in SWRCB Res. 88-63, "Sources of Drinking Water" (SWRCB 1988), and Water Board Res. 89-39 for groundwater west of Saratoga Street at Alameda Point (Water Board 2003). Res. 89-39 includes groundwater beneath IR Site 34.

In addition, EPA stated that based on (1) the shallow depth of the aquifer in this area, (2) the likelihood of saltwater intrusion (based on directions of groundwater flow) if any significant pumping takes place, and (3) the fact that no wells currently exist within or close to this area, it seems unlikely that groundwater in this area will be a potential source of drinking water in the future (EPA 2000a).

Therefore, based on the following, groundwater beneath Site 34 is not reasonably expected to serve as a public drinking water supply: (1) drinking water is supplied to Alameda Point by the East Bay Municipal Utilities District; (2) the Water Board provided the Navy with a letter exempting groundwater west of Saratoga Street at Alameda Point, which includes groundwater beneath Site 34 from the beneficial use of drinking water, (3) although the FWBZ qualifies as a Class II aquifer under federal guidelines, the BCT concluded that groundwater at the site is unlikely to be used as a source of drinking water, and (4) Alameda County well construction standards require that all wells be sealed and screened below the first confining layer in a shallow aquifer system and the FWBZ is a shallow unconfined aquifer.

## **2.6 SURFACE WATER DRAINAGE SYSTEM AND TIDES**

The FWBZ is tidally influenced on the northern, western, and southern sides of Alameda Point. Tidal influence studies indicated the region of influence extends about 250 to 300 feet inland on the northern and southern sides of Alameda Island and about 1,000 to 1,500 feet inland on the west side. Daily tidal fluctuations measured in the FWBZ ranged from 0.1 to 4 feet. Based on the measurements in monitoring wells and piezometers screened in the SWBZ for the central portion of Alameda Island, the amplitude of groundwater level fluctuations due to tides ranged from 0.07 to 2.22 feet (PRC Environmental Management, Inc. [PRC] 1997b).

Streams or ponds are not naturally occurring at Alameda Point. As a result, precipitation evaporates into the atmosphere, infiltrates to groundwater, or runs off into the storm drain system. Rainfall is likely to cause minor ponding, as well as groundwater infiltration, in the unpaved areas at IR Site 34. Surface water runoff flowing directly into the Oakland Inner Harbor could also occur. Oakland Inner Harbor is contiguous with the San Francisco Bay. The water level in the Bay is not affected by seasonal changes, but tidal fluctuations of 4 to 9 feet occur daily.

## **2.7 ECOLOGICAL HABITATS**

Alameda Point contains the following six major terrestrial and aquatic wildlife habitats identified for an Environmental Impact Report for the facility (City of Alameda 2003), and descriptions of

the habitat are supplemented by a site visit and information from the California Wildlife Habitat Relationships System (California Department of Fish and Game [CDFG] 2005):

- Open Water Area
- Grassland
- Landscaped or Developed
- Intensively Developed
- Airfield (Paved) Area
- Rock Breakwaters and Rip Rap

IR Site 34 is considered an Intensively Developed area and is bordered by Open Water Area and RipRap to the north, Grassland to the south, and Intensively Developed areas to the east and west. Intensively Developed areas have little vegetation and typical urban wildlife, such as California ground squirrel, scrub jays, and American robins, may be observed in these areas but to a lesser extent than in the landscaped/developed areas, because less foraging habitat is available in these areas (Navy 1999a). Feral cats also are found in the intensively developed area.

Dominant plant species in the nonnative grassland habitat to the south include ryegrass (*Lolium perenne*), yellow sweet clover (*Melilotus officinalis*), and common plantain (*Plantago major*). Blacktailed jackrabbits (*Lepus californicus*), Canada geese (*Branta canadensis*); and European starlings (*Sturnus vulgaris*) are the dominant animal species in this habitat (Navy 1999a). Species composition and density vary depending on the amount and type of vegetation present. This habitat supports wildlife that have adapted to disturbed environments.

Riprap and a potential saline emergent wetland area line the northern boundary of IR Site 34 along the shoreline of the Oakland Inner Harbor, and an additional potential seasonal wetland occurs in the southwest corner of the site. These potential wetlands have not been formally delineated. In 2001, a wetland delineation was conducted on the northern edge of Site 15, which is located to the east of Site 34, and about 1 acre of the site is classified as wetlands (Tetra Tech 2001a). Dominant plant species in that wetland area include pickleweed (*Salicornia virginica*), Carolina geranium (*Geranium carolinum*), and prickly lettuce (*Lactuca serriola*). Feral cats have been observed in the riprap near the potential wetland. During the site visit, a small area of geraniums (*Geranium carolinum*) and prickly lettuce (*Lactuca serriola*), as well as other unidentified wetland plants, were observed in the potential seasonal wetland in the southwest corner of Site 34. The potential wetlands provide minimal habitat to support plant and invertebrate populations, and the potential wetland to the north is tidally inundated at such a frequency as to not provide suitable habitat for small mammals. In addition, because of high marine vessel activity in the Oakland Inner Harbor it is unlikely that this area will be used by nesting birds.

Possible wetlands are discussed further in Appendix I.

## 2.8 INITIAL CONCEPTUAL SITE MODEL AND EXPOSURE UNIT IDENTIFICATION

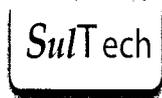

Previous investigations indicated the most probable sources for most of the chemicals detected at IR Site 34 are sandblasting grit, waste paint material, transformers, ASTs, and chemical storage. Soil and groundwater are expected to be the primary exposure media through ingestion, inhalation, and direct contact exposure routes. Migration of chemicals along fuel line or storm sewer bedding material (if present) may also occur. Chemicals sorbed to surface soils also may be transported by the wind. Potential human receptors at IR Site 34 include commercial/industrial workers, construction workers, residents, and recreational receptors, which could be exposed to on-site soils. Based on this information, in addition to known current and expected future reuse for IR Site 34, an initial CSM was developed and is presented on Figure 2-6.

IR Site 34 is currently unoccupied land. The planned reuse of this area is recreational and includes the development of a golf course. To be conservative and maximize future reuse potential, the Navy has evaluated the potential risks to potential future commercial/industrial workers, construction workers, and residents. These receptors could be exposed to shallow soil, deeper soil (through dermal contact), or groundwater (through inhalation of VOCs).

### 3.0 INVESTIGATION APPROACH AND SCOPE

Analytical data collected under environmental investigations at IR Site 34, including the RI fieldwork investigation, were combined to form a comprehensive data set for the site. The sections below describe how this data set and the CSM presented in Section 2.8 were used in the RI to define the nature, extent, fate, and transport of contaminants on site and the risk posed to potential human and ecological receptors.

#### 3.1 DATA QUALITY OBJECTIVES AND ASSESSMENTS

DQOs are qualitative and quantitative statements developed through the seven-step DQO process (EPA 2000b). The DQOs clarify the study objective, define the most appropriate data to collect and conditions for which to collect data, and specify tolerable limits on decision errors that will be used as the basis for establishing the quantity and quality of data needed to support decision-making. DQOs are used to develop a scientific and resource-effective design for data collection. The project-specific DQOs and the CSM developed for the investigation and evaluation of IR Site 34 are presented in Table 3-1 and Figure 2-6, respectively.

In order to fulfill DQOs, the analytical data gathered must be usable. The chemical analytical program for the IR Site 34 data set included the following analyses and methods:

- Metals by SW-846 EPA Method 6020/7470A&7471A (EPA 1996)
- Hexavalent chromium by EPA Method 7196A (EPA 1996)
- VOCs by the SW-846 EPA Methods 5035 and 8260B (EPA 1996)
- SVOCs by the SW-846 EPA Method 8270C (EPA 1996)
- PAHs by SW-846 EPA Method 8270C Selective Ion Monitoring (EPA 1996)
- Organochlorine pesticides by SW-846 EPA Method 8081A (EPA 1996)
- PCBs by SW-846 EPA Method 8082 (EPA 1996)
- Chlorinated herbicides by SW-846 EPA Method 8151A (EPA 1996)
- TPH as purgeables by the State of California Leaking Underground Fuel Tank (LUFT) Field Manual (State of California 1989) and by SW-846 Methods 5035 and 8015A (EPA 1996)
- TPH as extractables according to the State of California LUFT Field Manual (State of California 1989) and by SW-846 EPA Method 8015A (EPA 1996)
- TDS by Methods for Chemical Analysis of Water and Wastes 160.1 (EPA 1983)

Laboratory analytical data collected for these methods were validated according to procedures outlined in the EPA Contract Laboratory Program National Functional Guidelines for Inorganic and Organic Data Review (EPA 1994, 1999, 2004c). Although some qualifiers were added to the data, a final review of the data set with respect to the EPA data quality parameters indicated the data are of high overall quality (see Appendix F). The data meet all the requirements of the precision, accuracy, representativeness, completeness, and comparability data quality indicators described in EPA guidance for quality assurance project plans (EPA 2001a) and are usable for risk assessment purposes. The overall assessment of the sampling program, quality assurance (QA) and quality control (QC) data, data review, and data validation results indicates that these investigation data are of acceptable precision, accuracy, representativeness, completeness, and comparability.

The EPA Risk Assessment Guidance for Superfund (RAGS) was used to determine the usability of the validated data (EPA 1991). Exhibit 5-5 in RAGS states that data qualified as estimated (J) based on data validation reports should be used in quantitative risk assessments. Although this guidance is specifically for HHRAs, the same usability criteria were used for all IR Site 34 data. Except for nondetected results in one groundwater sample analyzed for pesticides that were qualified as rejected (R), all remaining data were appropriate for use in the RI Report and corresponding risk assessments.

### **3.2 BACKGROUND COMPARISON**

Background concentrations of metals have been established for soil and groundwater at Alameda Point. The data set considered to represent naturally occurring metals or background conditions was selected using a series of statistical tests conducted on data sets for each sample medium. Details of the construction of the background data sets are provided in Appendix G.

As presented in the background comparisons report for soil, areas of Alameda Point with geologically similar soils that represent a single background data set were designated as pink, blue, or yellow areas (PRC 1997a). These areas correspond with a particular fill event provided as follows and shown on Figure 3-1.

- Pink Area: Runway area and central portion of Alameda Point (Fill Area 1)
- Blue Area: Southeast portion of Alameda Point (Fill Area 2)
- Yellow Area: Far west portion of Alameda Point (Fill Area 3)

IR Site 34 is located in the Pink Fill Area. The background soil comparison in this RI Report was performed by comparing analytical results from soil samples collected at IR Site 34 with the Pink Fill Area data set. The upper bound (95 percentile) of the distribution was calculated for each metal included in the Pink Fill Area data set. The upper-bound value was used as an initial indicator to determine how many analytical results exceeded background concentrations.

Details of the construction of the background groundwater data set are provided in the "Technical Memorandum for Estimation of Ambient Metal Concentrations in Shallow Groundwater" (Tetra Tech 1998a). The background groundwater comparison in this RI Report was performed by comparing analytical results from shallow groundwater samples collected at IR Site 34 with the established background data set. The upper bound (95 percentile) of the distribution was calculated for each metal included in the background groundwater data set. The upper-bound value was used as an initial indicator to determine how many analytical results exceeded background concentrations.

Two-population statistical tests were used to compare metals concentrations in IR Site 34 soil and groundwater samples with background concentrations determined for Alameda Point. The background comparison procedures are described in greater detail in Appendix G. The following methods were used to conduct two-population tests, depending on the relative frequency of detection and sample size of each of the populations being compared:

- Wilcoxon rank sum (WRS) and Gehan-Wilcoxon (GT) tests
- Test of proportions
- Quantile test (QT)

One-sided statistical tests were used in all cases and employ a Type I error rate of 0.05. WRS and GT tests were used for metals with at least 60 percent detected data and single detection limits in both the site and background populations. Testing was performed using the nonparametric WRS test. For chemicals with fewer than 60 percent detected data, the detection frequencies in the site and background populations were compared using the test of proportions. The QT was conducted for all chemicals with less than 60 percent detected data and for all cases where either the WRS or GT test did not reject the null hypothesis (that is, when it was concluded that the median concentrations at the site and background concentrations were not significantly different) (Navy 1999b).

Background concentrations of metals in soil and groundwater were used to support the nature and extent evaluation, fate and transport evaluation, HHRA, and SLERA. Background concentrations of metals in soil and groundwater are presented in Tables 3-2 and 3-3, respectively.

### 3.3

## METHODS AND APPROACH FOR NATURE AND EXTENT EVALUATION

A data set that included all of the validated analytical data from IR Site 34 was evaluated to determine the nature and extent of chemicals in soil and groundwater. For the purposes of this RI Report, contamination is defined as a chemical detected in an environmental sample at IR Site 34 at a concentration exceeding comparison criteria. The following comparison criteria were used to evaluate the nature and extent of contamination in soil at IR Site 34:

- 2004 EPA and California-modified residential PRGs (EPA 2004e)
- 2004 EPA and California-modified industrial PRGs (EPA 2004e)
- Water Board environmental screening levels (ESL) for diesel, gasoline, and motor oil in shallow soil where groundwater is not a current or potential source of drinking water (Water Board 2005)
- The upper-bound (95 percentile) concentration of the distribution of metals in background soil samples from the Pink Fill Area

These comparison criteria were applied to both analytical results from fixed-laboratory analyses and from a portable x-ray fluorescence (XRF) unit, which was used to measure chromium and lead concentrations in 106 soil samples during the RI field investigation. Field XRF readings were used as a screening tool to estimate the extent of metals contamination in areas where paint waste was suspected. XRF field screening is a rapid and economical approach for estimating metals concentrations; XRF allows analysis of many more samples than can be done by a fixed laboratory with available time and financial resources. Twenty percent of XRF samples were also submitted to a fixed laboratory for analysis. Table D-2 in Appendix D presents results of XRF field screening and results from fixed-laboratory analysis for the collected soil samples, and Appendix E presents the analytical results for groundwater samples. Although a correlation study was not performed, qualitative comparison of XRF and fixed-laboratory data suggested XRF results for chromium and lead have a high bias relative to fixed-laboratory results, thus chromium and lead contamination on site was exaggerated. Laboratory analyses are considered more accurate than XRF screening results because more stringent QA/QC procedures were applied to the laboratory data (including independent data validation). XRF screening results are used to show areas of possible metals contamination, as discussed in Section 4.1.1. Numerical results from XRF field screening were not included in statistical calculations or used to support the risk assessment.

PAHs in soil were evaluated relative to B(a)P equivalents. B(a)P equivalents were calculated by multiplying the detected concentrations of the cancer PAHs by appropriate toxicity equivalency factors (TEF), then adding the resulting values to obtain a total B(a)P-equivalent value for individual samples. The TEFs are based on the cancer potency of each compound relative to B(a)P (EPA 1993a, OEHHA 2001). Previous agreements between the Navy and regulatory agencies established screening level of 0.62 milligram per kilogram (mg/kg) for PAHs (Navy 2001b), so a screening criterion of 0.62 mg/kg was used for B(a)P equivalents in soil. The EPA

and Cal/EPA TEFs for the seven PAHs that are considered by EPA to be probable human carcinogens are as follows.

Chemical	EPA Toxicity Equivalency Factor	Cal/EPA Toxicity Equivalency Factor
B(a)P	1.0	- 1.0
Benz(a)anthracene	0.1	0.1
Benzo(b)fluoranthene	0.1	0.1
Benzo(k)fluoranthene	0.01	0.1
Chrysene	0.001	0.01
Dibenz(a,h)anthracene	1.0	1.1
Indeno(1,2,3-c,d)pyrene	0.1	0.1

Comparison criteria for groundwater samples were modified from the criteria suggested in the RI Work Plan (SulTech 2006) based on exposure pathways in the CSM. The Water Board has found that groundwater in the FWBZ and SWBZ underlying IR Site 34 is not a potential source of drinking water (Water Board 2003). Therefore, comparison of chemical concentrations in groundwater at IR Site 34 with standards for drinking water is inappropriate and excessively conservative. The following comparison criteria were used to evaluate the nature and extent of contamination in groundwater at IR Site 34:

- EPA tap water PRGs (EPA 2004e)
- Water Board groundwater ESLs for evaluation of potential vapor intrusion concerns (Water Board 2005)
- The upper-bound (95 percentile) concentration of the distribution of metals in background shallow groundwater samples from Alameda Point

Potential risk from groundwater by the vapor intrusion pathway is evaluated in the HHRA (see Section 3.5 and Appendix H). Potential risk from groundwater to aquatic receptors is evaluated in the SLERA qualitative evaluation through a comparison with aquatic comparison criteria (see Section 3.6 and Appendix I).

The nature and extent evaluation assesses whether contamination data gaps are present at IR Site 34. Although TPH is not a CERCLA contaminant, it is addressed in the nature and extent evaluation because fuels and lubricants were used at various locations across the site and an objective of this RI is to meet TPH closure requirements. Section 4.0 presents the results of the nature and extent evaluation for contamination in soil and groundwater at IR Site 34.

### 3.4 METHODS AND APPROACH FOR FATE AND TRANSPORT EVALUATION

This evaluation assesses whether chemicals identified in the nature and extent evaluation as exceeding comparison criteria have migrated or degraded, are being released from a continuing source of contamination, or are likely to be distributed by groundwater or other potential pathways. This evaluation used geological and hydrogeological properties in combination with chemical data and primarily included the following steps:

- Identify soil and groundwater sampling locations with the maximum concentrations of chemicals detected above comparison criteria
- Identify the presence of breakdown or parent products for chemicals detected above comparison criteria
- Evaluate the effect of groundwater flow or other potential pathways on the distribution of chemicals detected above comparison criteria

The fate and transport evaluation emphasizes the chemical pathways and release mechanisms identified in the CSM (see Figure 2-6). Section 5.0 presents the results of the fate and transport evaluation for contamination in soil and groundwater at IR Site 34.

### 3.5 METHODS AND APPROACH FOR HUMAN HEALTH RISK ASSESSMENT

The purpose of the HHRA at IR Site 34 is to quantify the potential for adverse health risks associated with potential exposure to chemicals in the environment. The methods and assumptions used in this RI Report were selected or developed to be consistent with Navy, EPA, and DTSC guidelines for baseline HHRA's (EPA 1991, DTSC 1992, Navy 2001a). In accordance with the EPA risk assessment model, the process of conducting an HHRA included the following four steps (EPA 1991):

- **Data Evaluation and Selection of Chemicals of Potential Concern** – Collect and analyze data and select COPCs (see Section 3.5.1)
- **Exposure Assessment** – Analyze sources of contamination, identify receptors and pathways of exposure, and estimate exposure point concentrations (EPC) and chemical intakes (see Section 3.5.2)
- **Toxicity Assessment** – Collect toxicity information and select toxicity values (see Section 3.5.3)
- **Risk Characterization** – Characterize potential health effects and summarize risk information (see Section 3.5.4)
- **Uncertainty Analysis** – Analyzes the major uncertainties associated with the calculated risks (see Section 3.5.5)

Methods and assumptions used to perform each of these steps are described in the subsections below. Section 6.0 summarizes the results of the HHRA for IR Site 34. The complete baseline HHRA for IR Site 34 is presented in Appendix H.

### **3.5.1 Data Evaluation and Selection of Chemicals of Potential Concern**

The objective of data evaluation is to develop a list of COPCs for risk assessment purposes. COPCs are defined as the subset of chemicals at a site most likely to present a potential health risk. A limited list of COPCs is desirable when the list of detected chemicals (1) exceeds 80 detected chemicals, as suggested in RAGS (EPA 2001d), or (2) requires intensive modeling. However, based on agreement with the regulatory agencies, the HHRA quantitatively evaluated all chemicals detected in soil and groundwater, except for essential nutrients (calcium, magnesium, potassium, and sodium).

Data were considered to be appropriate for use in the HHRA if they (1) were validated, (2) were not qualified as rejected ("R"), (3) met the DQOs for the RI (set forth in the task-specific sampling and analysis plan[s]) (SulTech 2006), and (4) reflect current site conditions. In general, the HHRA did not use field data, screening-level data (including XRF data), and data collected to characterize potential historical releases but physically present in paved structures (such as sediment from drain piping or oil-water separators). Section H4.0 in Appendix H provides additional detail on the data and methods used to select COPCs.

### **3.5.2 Exposure Assessment**

The exposure assessment in the HHRA identifies the ways in which humans may come into contact with COPCs at IR Site 34 under current or potential future uses of the site. The quantitative assessment of human exposure to chemicals in the environment involves the following steps:

- Identify potentially complete exposure pathways and determine how and with what frequency and magnitude individuals may be exposed to the chemical concentrations under various exposure scenarios (see Section 3.5.2.1)
- Estimate the chemical concentrations or EPCs in the environment (such as soil, water, and air) to which individuals may be exposed (see Section 3.5.2.2)
- Estimate Chronic Daily Intakes (CDI). Appendix H describes the methods used to calculate CDIs.

The combinations of exposure scenarios and pathways described below are shown in the CSM for the HHRA at IR Site 34 (see Figure H-1 in Appendix H).

### 3.5.2.1 *Potential Receptors and Exposure Pathways*

The HHRA evaluates potential risks to humans through the exposure pathways identified in the CSM. Potential human health risks associated with exposure to chemicals at IR Site 34 were evaluated for relevant current and/or future human populations and land uses in accordance with RAGS Part A (EPA 1991). IR Site 34 is currently not used and access is restricted. Therefore, human receptors are not present at IR Site 34 at this time. Potential future human receptors at IR Site 34 include:

- Commercial/industrial workers
- Construction workers
- Residents, both adults and children
- Recreational users, both adults and children

Although it is unlikely that IR Site 34 will be used to support residential use in the future, residential use was evaluated to address unrestricted use of the site. The intended future use of IR Site 34 is a recreational area and golf course, as discussed in Section 1.3.6. Groundwater is not a current or future source of drinking water at IR Site 34, and the risk assessment does not quantitatively evaluate domestic use of groundwater.

Exposure pathways assessed for potential future receptors at IR Site 34 include:

- Soil ingestion
- Dermal contact with soil
- Inhalation of nonvolatile chemicals bound to airborne soil particulates
- Inhalation of volatile chemicals in outdoor air from soil and groundwater
- Inhalation of volatile chemicals in indoor air that migrate from soil and groundwater in the vapor phase (commercial/industrial workers and residents only)
- Ingestion of homegrown produce (residents only)

Although it is acknowledged that construction workers also may have dermal contact with groundwater during excavation activities that intercept the shallow water table (located at about 4 feet bgs across the site), construction in saturated trench conditions is generally avoided and dewatering is quickly implemented for effective construction activities. Therefore, groundwater-related pathways of exposure for a construction worker are potentially complete, but are expected to be quantitatively negligible relative to all other pathways, and are not quantitatively evaluated in the HHRA for IR Site 34.

### **3.5.2.2 Exposure Points and Exposure Point Concentrations**

EPCs are the concentrations of chemicals in a medium (soil, water, or air) used to calculate risk to human health. The EPCs for chemicals in soil and groundwater were the lower of the 95th percent upper confidence limit of the arithmetic mean (95UCL) sample concentration and the maximum sample concentration. The 95UCL is defined as a value that, when calculated repeatedly for randomly drawn subsets of site data, equals or exceeds the true mean 95 percent of the time (EPA 1992). Use of the 95UCL is better for predicting actual chronic exposure conditions because the 95UCL is an upper-bound estimate of the average exposure concentration (that is, the resulting EPC accounts for the probability of long-term random contact with contaminated areas). Section H5.3.1 of Appendix H describes the specific methods used to calculate the 95UCL.

The HHRA calculated EPCs in soil based on data segregated into the following data sets:

- Surface Soil Data (0 to 2 feet bgs): Soil data from this depth interval were applied to commercial/industrial workers, construction workers, residents, and recreational users.
- Subsurface Soil Data (0 to 4 feet bgs): Because shallow groundwater is present at IR Site 34, soil data from the ground surface to the water table (located at approximately 4 feet bgs) were evaluated. Soil data from this depth interval were applied to commercial/industrial workers, construction workers, and residents.

Volatile chemicals in soil and groundwater may be released to outdoor air. The HHRA applied volatilization factors to the EPCs in soil and groundwater to calculate EPCs in outdoor air. Section H5.0 of Appendix H describes the methods used to calculate the volatilization factors.

Vapor intrusion modeling was used to calculate indoor air concentrations for future commercial/industrial workers and future residents in a future hypothetical building. The Johnson and Ettinger model (EPA 2004a and 2004b) was used to estimate the volatile emissions from contaminated soil and groundwater. The model parameters listed as default values in EPA's model were replaced with California-specific parameters listed in DTSC's vapor intrusion model (DTSC 2005a). The DTSC-modified version of the EPA vapor intrusion model uses soil and groundwater data to calculate indoor air concentrations. The vapor intrusion model usually results in very conservative risk assessment results. Appendix H provides detailed descriptions of the methods used to calculate EPCs in indoor.

### **3.5.3 Toxicity Assessment**

The objective of the toxicity assessment is to evaluate the relationship between dose and toxic response for each COPC identified during the COPC selection process. The toxicity assessment identifies toxicity criteria (values) for each chemical chosen for inclusion in the risk assessment and the kind of effect each chemical could produce. The toxicity values used in the HHRA are

cancer slope factors (CSF) (in units of mg/kg per day [mg/kg-day]) for cancer effects and reference doses (RfD) (in units of mg/kg-day) for chronic exposures associated with noncancer effects.

The HHRA used a dual-tracking approach to consider both EPA and DTSC toxicity values. To satisfy federal (Navy and EPA) and state (DTSC) requirements, this HHRA prepared a set of risk assessment results using EPA toxicity values, referred to as Method 1, and a separate set of risk assessment results using DTSC toxicity values, referred to as Method 2.

Toxicity factors for Method 1 were compiled from EPA-approved sources using the following hierarchy:

- EPA's Integrated Risk Information System (IRIS) Values: IRIS is an online database that contains EPA-approved RfDs and CSFs (or reference concentrations [RfC] and unit risk factors converted to RfDs and CSFs) (EPA 2005a). The RfDs and CSFs have undergone extensive review and have agency-wide consensus.
- EPA's Provisional Peer-Reviewed Toxicity Values (PPRTV): PPRTVs are presented in the EPA Region 9 PRG table (EPA 2004e). PPRTVs were developed by the Office of Research and Development/National Center for Environmental Assessment, and Superfund Health Risk Technical Support Center when requested by EPA's Superfund program (EPA 2004f).
- Other EPA Sources: These sources include provisional values from the National Center for Environmental Assessment as presented in the EPA Region 9 PRG table (EPA 2004e), and EPA's Health Effects Assessment Summary Tables (HEAST) (EPA 1997a).

Toxicity factors for Method 2 used State of California CSFs developed by the Office of Environmental Health Hazard Assessment (OEHHA). These CSFs are available from the "Toxicity Criteria Database" (OEHHA 2007). If an OEHHA CSF was not available, the EPA hierarchy was followed to select CSFs. In addition to CSFs, OEHHA has developed reference exposure levels (REL) to assess noncancer endpoints of inhalation exposures (OEHHA 2005); however, RELs were not subjected to as stringent a peer review as federal RfCs available from IRIS. As a result, the HHRA used the prioritization summarized below for inhalation noncancer toxicity values in the risk characterization of COPCs selected under Method 2:

- The EPA IRIS RfC or inhalation RfD was used if the value was based on an inhalation study.
- The OEHHA REL was used if the EPA IRIS inhalation RfD was extrapolated from an oral study.
- The OEHHA REL was used if no EPA IRIS RfC or inhalation RfD value was available.

- An alternative source (such as PPRTVs, HEAST, or route-extrapolated values) was used if no EPA IRIS RfC or inhalation RfD value was available and no OEHHA REL was available.

Finally, because OEHHA has not developed its own set of toxicity values for assessing noncancer endpoints for oral or dermal exposures, the EPA hierarchy was followed to select noncancer oral and dermal toxicity values for risk characterization of the COPCs identified under Method 2.

Lead is a chemical of particular toxicological concern wherever children or other sensitive subpopulations may be exposed to lead-contaminated media. However, no accepted toxicity values are available for lead. Evaluation of lead in the HHRA is based on noncancer effects. The potential for human health effects caused by lead was estimated through blood-lead concentration modeling. DTSC's LeadSpread Version 7 model (DTSC 1998) was used to estimate blood-lead concentrations in residential adults and children, and the resulting blood-lead concentrations were compared with target blood-lead levels established by DTSC.

### 3.5.4 Risk Characterization

Risk characterization combines the exposure and toxicity assessments to produce quantitative estimates of health effects for COPCs. The health effects of a chemical are quantified in terms of cancer risk if the chemical is considered to be a carcinogen, as well as noncancer health effects (all adverse health effects other than cancer). The potential for both types of effects was evaluated because chemicals may present noncancer health effects in addition to cancer risks.

Risk characterization results are presented in Section 6.0 for all COPCs and each exposure scenario identified at IR Site 34. Emphasis is placed on the following three factors:

- Results of the reasonable maximum exposure (RME) scenario
- Exposure scenarios that exceed the acceptable risk management range
- Pathways and specific chemicals (risk drivers) that contribute most significantly to these health risk estimates

For chemicals not classified as carcinogens and for carcinogens known to cause adverse health effects other than cancer, the potential for exposure to result in adverse health effects other than cancer are evaluated by comparing the CDI with an RfD. For a single chemical, the comparison yields a ratio called the hazard quotient (HQ), which was calculated as follows:

$$HQ = \frac{CDI (mg/kg-day)}{RfD (mg/kg-day)}$$

To evaluate the potential for adverse health effects other than cancer from simultaneous exposure to multiple chemicals, the HQs for all chemicals were summed to yield a hazard index (HI) as follows:

$$HI = \sum HQs$$

Pathway-specific HIs were then summed to estimate a total HI for each receptor identified in the exposure assessment. Noncancer effects are exposure duration-dependent. Therefore, the HIs for the child were used to streamline the discussion and risk management information. The HIs for the child resident are higher because the dose and contact rates are greater relative to a smaller body weight.

Risks associated with exposure to chemicals classified as carcinogens were estimated as the incremental probability that an individual will develop cancer over a lifetime as a direct result of exposure (EPA 1991). The estimated risk is expressed as a unitless probability. Three steps were used to estimate cancer risks for chemicals classified as carcinogens. First, the CDI was multiplied by the chemical-specific CSF to derive a cancer risk estimate for a single chemical and pathway. The calculation is based on the following relationship:

$$\text{Chemical-Specific Cancer Risk} = \text{CDI (mg/kg-day)} \times \text{CSF (mg/kg-day)}^{-1}$$

Second, the individual chemical cancer risks were assumed to be additive to estimate the cancer risk associated with exposure to multiple carcinogens for a single exposure pathway, as follows:

$$\text{Pathway-Specific Cancer Risk} = \sum \text{Chemical-Specific Cancer Risks}$$

Third, pathway-specific risks were summed to estimate the total cancer risk.

$$\text{Total Cancer Risk} = \sum \text{Pathway-Specific Cancer Risk}$$

### 3.5.5 Uncertainty Analysis

Varying degrees of uncertainty exist at each stage of the HHRA. These uncertainties arise from assumptions made in the risk assessment and limitations of the data used to calculate risk estimates. Uncertainty and variability are inherent in the exposure assessment, toxicity values, and risk characterization. EPA guidance (1991) states the following (emphasis from the original):

There are several categories of uncertainties associated with site risk assessments. One is the initial selection of substances used to characterize exposures and risk on the basis of the sampling data and available toxicity information. Other sources of uncertainty are inherent in the toxicity values for each substance used to characterize risk. Additional

uncertainties are inherent in the exposure assessment for individual substances and individual exposures. These uncertainties are usually driven by uncertainty in the chemical monitoring data and the models used to estimate exposure concentrations in the absence of monitoring data, but can also be driven by population intake parameters. Finally, additional uncertainties are incorporated in the risk assessment when exposures to several substances across multiple pathways are summed.

Sources of uncertainty in the IR Site 34 HHRA process are described in detail in Section H9.0 of Appendix H. The uncertainty analysis includes discussions related to the following:

- Uncertainty in data selection and COPC selection process
- Uncertainty in exposure assessment (exposure scenarios and pathways, EPCs, application of predictive models and the use of exposure models, and exposure variables)
- Uncertainty in toxicity values selected for use in the HHRA
- Uncertainty in risk characterization

### **3.6 METHODS AND APPROACH FOR SCREENING-LEVEL ECOLOGICAL RISK ASSESSMENT**

The purpose of the SLERA at IR Site 34 is to use conservative assumptions and available scientific literature to evaluate potential risk to ecological receptors in an approach consistent with Steps 1 and 2 of the eight-step process described in EPA guidance (EPA 1997, 1998, 1999a, 1999b, 2000b). The methods and assumptions used to complete the SLERA were selected or developed to be consistent with RI work plan (Sultech 2006), Navy policy for conducting ecological risk assessments (ERA) (Navy 1999a, 2004), which is parallel to the EPA guidelines for the eight-step ERA process for Superfund sites (EPA 1997b), and EPA guidance. The first two components of the DTSC process (scoping assessment and Phase I predictive assessment) (DTSC 1996a, 1996b) are consistent with the EPA and Navy approaches. Substantive elements of the guidance provided by all three agencies were considered in the development of this SLERA.

Navy guidance (1999) indicates that an intermediate refinement step may be conducted (Step 3a risk refinement) if the SLERA indicates unacceptable or uncertain risk. If the data evaluated in Steps 1 and 2 indicate risk to receptors at IR Site 34, then the Navy will initiate the risk refinement step (Step 3a) of the baseline ERA. Once this process is complete, a scientific management decision is made on the site's status and whether further evaluation in a baseline ERA is necessary (EPA 1997, 2001).

The SLERA includes the following components:

- Step 1 - Exposure Evaluation
  - Environmental Setting and COPECs
  - Chemical fate and transport mechanisms (operational)
  - Mechanisms of ecotoxicity (broad classes of COPECs)
  - Potentially complete exposure pathways
- Step 2 – Risk Characterization
- Step 3a – Risk Refinement

Results of the SLERA were used to evaluate if a baseline ERA (Steps 3 through 8 in the EPA ERA process) is warranted at IR Site 34. Results of the SLERA, including recommendations on completion of a baseline ERA, are summarized in Section 7.0. The complete SLERA is presented in Appendix I.

### **3.6.1 Exposure Evaluation**

The exposure evaluation identifies an ecological conceptual site model (CSM) that addresses:

- Environmental setting and COPECs
- Chemical fate and transport mechanisms
- Mechanisms of ecotoxicity (broad classes of COPECs)
- Potentially complete exposure pathways

An assessment of site characteristics and ecological habitats, representative organisms, and threatened and endangered species that exist or have to the potential to exist at IR Site 34 was conducted. COPECs were identified and the fate and transport mechanisms of the COPECs were evaluated to determine if the chemicals have the potential to reach ecological receptors. The ecotoxicity of the COPECs also was examined to understand the potential adverse effects to ecological receptors. Finally, the potential exposure pathways between COPECs and ecological receptors were evaluated.

Similar to the COPC selection process in the HHRA, a list of COPECs was developed for screening-level risk assessment purposes. COPECs are the subset of chemicals that are most likely to present a potential risk to ecological receptors. The soil and groundwater data sets used in the HHRA also form the basis for the SLERA. Soil COPECs were identified from analytical data collected from 0 to 4 feet bgs. Although groundwater will undergo dilution upon entering

the Bay, the SLERA uses the monitoring well concentration data as a conservative (protective) estimate. Groundwater COPECs were identified from analytical data collected from wells located at IR Site 34. COPECs include all chemicals detected above the detection limit at least once. Any chemical not detected above the quantitation limit was eliminated as a COPEC. Per EPA guidance (1989), essential nutrients (calcium, magnesium, potassium, and sodium) were excluded as COPECs. Although essential nutrients may be present at concentrations above naturally occurring levels, they are eliminated as COPECs because they are only toxic at levels higher than those found at the site. In accordance with Navy policy (2001b, 2004), data for IR Site 34 are not screened against background (ambient) concentrations until the COPEC refinement process in Step 3a of the baseline ERA, if Step 3a is necessary. Consistent with the RI work plan (Tetra Tech 2006) EPC for soil were based on the maximum detection of each COPEC and were assumed to represent site-wide concentrations. For the qualitative evaluation of groundwater, the EPC was the lower of the maximum concentration and the 95UCL; however, the 95UCL was calculated only for the chemicals that were associated with more than three detections.

Receptors were selected based on their ability to reside in the habitats at or within the vicinity of IR Site 34. Site 34 is within Intensively Developed area and supports little vegetation. Typical urban wildlife, such as California ground squirrels, scrub jays, and American robins, may be observed in these areas, but to a lesser extent than in the landscaped/developed areas, because less foraging habitat is available in these areas. For an exposure pathway to be considered complete, a COPEC must be able to travel from the source to ecological receptors and to be taken up by the receptors through one or more exposure routes. Potentially complete exposure pathways were evaluated for IR Site 34 based on fate and transport properties, including food chain transfer. Complete exposure pathways were identified before the quantitative evaluation of toxicity was completed so the assessment focused on only the chemicals that can reach ecological receptors. For complete exposure pathways, potential toxic effects to ecological receptors and their habitats were identified for each COPEC. The ecological receptors were identified using information on species potentially occurring at the exposure areas.

Complete exposure pathways were identified for COPECs from soil to the deer mouse, California ground squirrel, American robin, Alameda song sparrow, and the red-tailed hawk. No complete exposure pathways were identified from groundwater to terrestrial receptors. However, a complete exposure pathway was identified from groundwater to aquatic life within Oakland Inner Harbor. It is unlikely that surface water runoff from IR Site 34 would affect the potential seasonal wetland located within the southwestern corner of the site because the site topography would prevent it from reaching this potential wetland. Although surface water generally flows towards the wetland located north of the site, precipitation typically evaporates into the atmosphere, infiltrates to groundwater, or runs off into the storm drain system. In addition, the wetland provides minimal habitat to support plant and invertebrate populations and is tidally inundated at such a frequency as to not present suitable habitat for small mammals.

The selection of assessment endpoints helps to define the adverse effects of site-related contaminants on ecological receptors, including plant and animal populations and communities, habitats, and sensitive environments (EPA 1998). An assessment endpoint represents a specific

ecosystem characteristic defined using an ecological entity and selected attributes. This methodology is described in greater detail in Appendix I.

The assessment endpoint selected for the SLERA was sufficient rates of survival, growth, and reproduction to sustain wildlife populations typical to the area. The selected measurement endpoints for terrestrial species were the California ground squirrel (*Spermophilus beecheyi*), the deer mouse (*Peromyscus maniculatus*), the American robin (*Turdus migratorius*), the Alameda song sparrow (*Melospiza melodia pusillula*), and the red-tailed hawk (*Buteo jamaicensis*). These measurement endpoints were selected based on the current and planned future use of IR Site 34 (see Appendix I).

The assessment of aquatic receptors is only addressed qualitatively in this SLERA. COPECs in groundwater were assumed to have no dilution, retardation, or degradation between the location where the COPEC was detected and the Oakland Inner Harbor. This is a conservative assumption that likely overestimates the risk from chemicals in groundwater at IR Site 34.

### 3.6.2 Risk Characterization

The second part of the SLERA is the preliminary risk characterization, Step 2. Risk calculations for each terrestrial receptor were prepared, which allowed for a quantitative estimation of risk based on exposure assumptions for the individual receptor. Risk calculations for each terrestrial receptor and COPEC consist of dividing the media-specific concentration by the appropriate estimated dose for birds and mammals. The risk is evaluated using a HQ. The HQ is calculated using the formula below:

$$HQ = Dose / TRV$$

If the HQ is greater than 1, there is assumed to be significant risk. However, if the HQ is less than or equal to 1, the risk is considered to be minimal. HQs are calculated using a dose assessment and a TRV. For this SLERA, both a low TRV and a high TRV were used wherever possible. Methods for calculating the dose and TRVs are briefly summarized below, and are fully described in Appendix I.

#### **Dose Assessment**

The dose is calculated for each measurement endpoint based on a variety of species-specific input factors. These input factors, as used in this SLERA, are intended to be conservative. The following input factors were identified for this SLERA:

- **Site Use Factors (SUF).** All species considered in this SLERA were assumed to live and feed within each site at all times.
- **Bioavailability.** All ecological COPECs were assumed to be 100 percent bioavailable for all trophic levels and species.

- **Body Weight and Food Ingestion.** The average body weight indicated in the literature (EPA 1993b, 2005; DTSC 2003) was used to calculate an ingestion rate based on the formulas presented in Navy 2001.
- **Bioconcentration Factors (BCF) and Bioaccumulation Factors (BAF).** Soil-to-plant and soil-to-soil invertebrate BCFs were obtained from various sources (Baes and others 2004, Bechtel-Jacobs 1998, EPA 2005, RAIS 2007, Sample, Opresko, and Sutter 1996, Sample and others 1998a, Sample and others 1998b, Sample and others 1999, Sample and Arenal 1999, US Air Force 2003).
- **Dietary Composition.** The diet of each of the receptors was based on the percentages of dietary items, as reported in the literature (Zeiner and others 1990; California Department of Fish and Game 2005).
- **Ecological COPEC Concentration.** The EPC used in the evaluation was based on the maximum detection of each COPEC.

The following equations were used to estimate the daily doses for terrestrial and avian receptors:

Ground squirrel/ deer mouse dose (mg/kg-day) =

$$(SUF) \frac{[(C_{soil})(IR_{soil}) + (C_{invert})(IR_{invert}) + (C_{plant})(IR_{plant})]}{BW}$$

Alameda song sparrow dose (mg/kg-day) =

$$(SUF) \frac{[(C_{soil})(IR_{soil}) + (C_{invert})(IR_{invert}) + (C_{plant})(IR_{plant})]}{BW}$$

American robin dose (mg/kg-day) =

$$(SUF) \frac{[(C_{soil})(IR_{soil}) + (C_{invert})(IR_{invert}) + (C_{plant})(IR_{plant})]}{BW}$$

Red-tailed hawk dose (mg/kg-day) =

$$(SUF) \frac{[(C_{ground\ squirrel})(IR_{ground\ squirrel}) + (C_{soil})(IR_{soil})]}{BW}$$

where

- $BW$  = Body weight  
 $C_{soil}$  = EPC of chemical in soil (mg/kg)  
 $C_{invert}$  =  $(C_{soil})(BCF_{soil-to-invert})$  (mg/kg-BW) (EPA 1999a)

- $C_{plant}$  =  $(C_{soil})(BCF_{soil-to-plant})$  (0.12 mg/kg-BW) (0.12 is a default value to convert the plant concentration from dry weight to fresh weight and is presented by EPA [1999b]. This value is an average based on 80 to 95 percent water content in herbaceous plants and non-woody plant parts.)
- $C_{ground\ squirrel}$  = Concentrations in ground squirrels were estimated using uptake models using concentrations at the site or by multiplying concentrations in soil at the site by BAFs for small mammals.
- $SUF$  = Site use factor

### **Toxicity Reference Values**

TRVs were used as guidelines in the evaluation of soil COPECs (DTSC 2000, 2002). The TRVs used were originally prepared by the Navy and the EPA Region 9 Biological Technical Assistance Group (BTAG) (Navy 1998). TRVs are provided as both an upper estimate and a lower estimate of effects thresholds. The low TRV is based on no-observed-adverse-effects-level (NOAEL) data, while the high TRV is based on the approximate midpoint of the range of effects levels. Adverse effects are likely to occur at the high TRV. No adverse effects are expected to occur at the low TRV; therefore, the TRVs used in this screening-level ERA represent low TRVs unless otherwise noted.

Navy-BTAG TRVs were used whenever available. If a Navy-BTAG TRV was unavailable for a COPEC, an appropriate TRV was selected from scientific literature. Data from chronic studies also were preferentially selected. If values selected from the literature did not represent chronic NOAELs, a factor of 0.1 was used to convert to a chronic value, and a value of 0.1 was used to convert to a NOAEL, where necessary. If a TRV for birds was unavailable for a COPEC, an adjustment factor of 0.1 was applied to a mammalian TRV. Appendix I provides further information on the derivation and use of TRVs.

### **Qualitative Evaluation of Aquatic Life**

Groundwater COPECs were evaluated qualitatively, using a two-step process. First, groundwater was screened by comparing the EPCs (the lower of the maximum concentration and the 95UCL) against four sets of aquatic comparison criteria. Any COPECs where the EPC exceeded any of the comparison criteria or for which there were no comparison criteria were retained for further evaluation in Step 3a. COPECs for which the EPC was below all of the comparison criteria were determined not to be risk drivers.

Groundwater concentrations were compared with the following criteria in the first step of the qualitative screening:

1. California Toxics Rule (CTR) criterion for protection of saltwater aquatic life in enclosed bays and estuaries (criterion continuous concentration [CCC], 4-day average, and criterion maximum concentration [CMC]). EPA intended for states to use the National Ambient Water Quality Criteria (NAWQC) to develop their own numeric water quality criteria as mandated in Section 303(c)(2)(B) of the Clean Water Act. California adopted statewide water quality criteria for the protection of aquatic life, as described in the CTR (EPA 2000c).
2. EPA National Recommended Water Quality Criteria for protection of saltwater aquatic life (EPA CCC, 4-day average, and EPA CMC): NAWQCs are set forth by EPA under the Clean Water Act Section 304(a)(1) and described in the National Recommended Water Quality Criteria (EPA 2006b). NAWQCs are intended to “accurately reflect the latest scientific knowledge” on the effects of chemicals on aquatic life. These criteria provide guidance for determining acceptable conditions for both marine and freshwater aquatic life.
3. Water Board’s Bay Plan values (4-day average, 1-hour average, and 24-hour average) (Water Board 2006).
4. Water Board’s surface water screening levels for marine habitats (Water Board 2005).

See Appendix I for further information regarding the qualitative evaluation.

### **3.6.3 Risk Refinement**

Refined exposure estimates were developed in accordance with Step 3a of Navy policy (Navy 1999a, 2001b) and EPA guidance (EPA 1997b). COPECs with HQs greater than 1 and a frequency of detection of 5 percent or greater, soil COPECs without TRVs, and groundwater COPECs that exceeded the four sets of aquatic threshold criteria were retained for further evaluation and risk refinement.

Refined risk estimations were prepared for all soil COPECs yielding HQs greater than 1 and with a frequency of detection of 5 percent or greater. Refined exposure estimates were used to derive refined risk estimations for each COPEC and terrestrial receptor pair.

The EPC for each soil COPEC was estimated as the lower of the 95UCL and the maximum detected concentration. Exposure factors were modified to reflect more realistic values for each receptor. This process was completed for any COPEC that yielded an HQ greater than 1 in the SLERA. Changes in the SUF only affected the red-tailed hawk because the home ranges of all other receptors were smaller than the area of IR Site 34. All other exposure factors remained unchanged, maintaining the conservative nature of the screening-level exposure estimates.

Groundwater COPECs retained for further evaluation in Step 3a were evaluated individually based upon the maximum and 95UCL concentrations compared to the four sets of threshold

criteria; a supplemental literature search for additional criteria; the sample location and date; and the groundwater data set.

### 3.6.4 Uncertainty Analysis

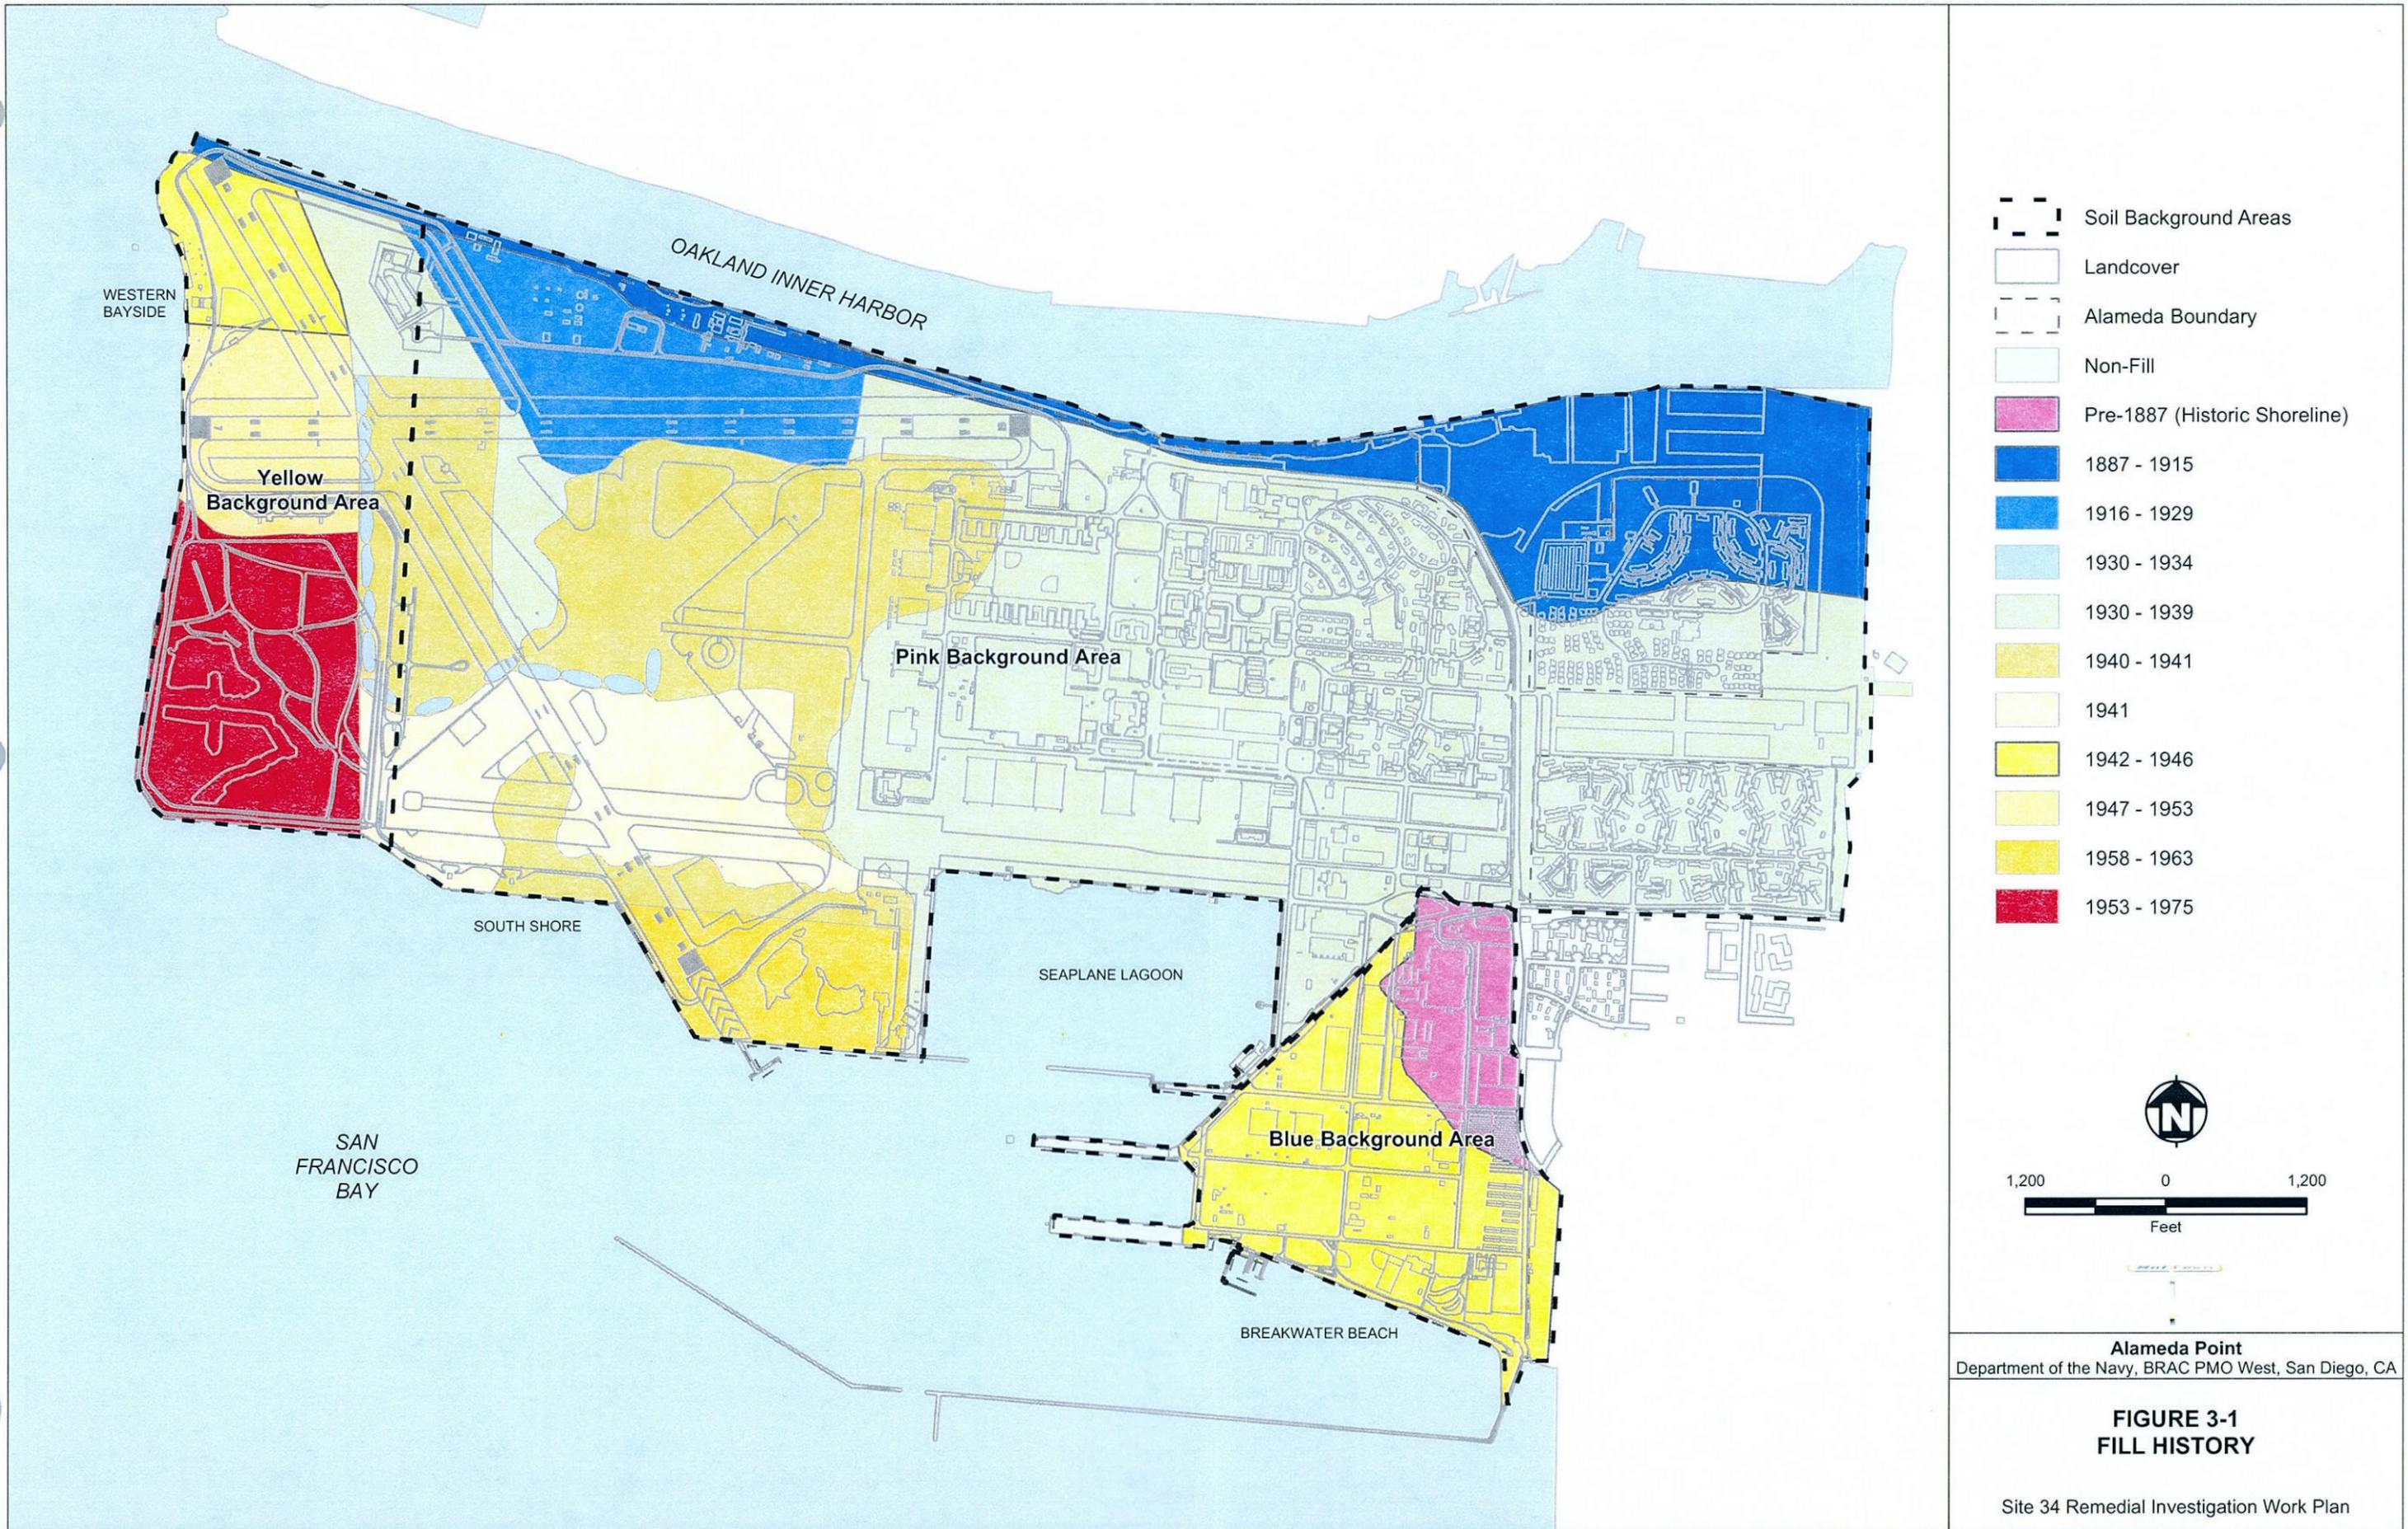

The SLERA process involves a large number of uncertainties and extrapolations to evaluate potential risk to ecological receptors. The following uncertainties are associated with the SLERA conducted for IR Site 34:

- SUFs – The risk calculations assumed that all receptors lived and fed in the area of the site at all times.
- Dietary Composition – the percent composition and type of prey ingested by various receptors was based on literature studies that were not site-specific. Additionally, the models were simplified to assume a limited diet, consistent with the literature data.
- Bioavailability – All COPECs were assumed to be 100 percent available to all receptors.
- Development of TRVs – The TRVs used in risk calculations were derived from literature studies. These studies were not conducted on the receptors used in this SLERA. TRVs were extrapolated using uncertainty factors to account for differences between the species.
- Qualitative Evaluation of Ecological COPECs – Studies were not available to develop TRVs for a number of measurement endpoints. The potential effects of these ecological COPECs were evaluated on a qualitative basis, relying heavily on professional judgment.
- BCFs – the use of the octanol/water partition coefficient ( $K_{ow}$ ) to calculate the biotransfer factor of chemicals into mammal tissue, and the BCFs for receptors can overestimate the uptake of organic chemicals into the tissues of organisms and plants

Overall, many of the assumptions in the SLERA are conservative and result in overestimates of site-specific parameters. In addition, because habitat is limited at Site 34 and future land use would not result in additional habitat, it is unlikely that ecological receptors would use the site in any significant manner. Appendix I provides a detailed discussion on uncertainty.

**TABLE 3-1: SITE 34 REMEDIAL INVESTIGATION DQO PROCESS**  
Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

1	2	3	4	5	6	7
State the Problem	Identify the Decisions	Identify Inputs to the Decisions	Define Study Boundaries	Develop Decision Rules	Specify Tolerable Limits on Error	Optimize Sampling Design
<p><b>Stakeholders:</b> Navy, regulatory agencies, and restoration advisory board</p> <p><b>Site History/Conceptual Site Model:</b> IR Site 34 is located in the north-central portion of Alameda Point, adjacent to the Oakland Inner Harbor. IR Site 34 is a 4.18-acre area that is partially paved, relatively flat open space. IR Site 34 was a NARF used to maintain base equipment such as scaffolding and other apparatus. The site was used primarily for painting services, storage, wood and metal shop activities, and sandblasting activities. IR Site 34 formerly comprised several structures, including Buildings 331, 330, 343, 475, 344, 510, 474, 477, 604, 476, 479, 472, and intervening open areas; seven ASTs (330A, 330B, 344A, 344B, 344C, 344D, and 331); GAPs 78 and 79; 15 transformers; and an aviation gasoline fuel line. All buildings, ASTs, GAPs, non-PCB transformers, and fuel lines were removed between 1996 and 2000, except for concrete pads.</p> <p>Fifty-four soil and 9 groundwater samples were collected during the 1995 EBS sampling event and during fuel line and other petroleum investigations between 1994 and 1999 to assess conditions associated with site use. EBS samples were collected from stained soil and discolored soil around the buildings, and in the open space in the southwest portion of the site. Results of soil samples from potential source areas at the site indicated the following chemicals exceeded residential PRGs: arsenic, cadmium, and lead (north of Building 510), chromium and lead (east of Building 344); and arsenic south of Building 331); PCBs (north of Building 331 and in the southwest portion of the site); and benzo(a)pyrene (north of Building 331). However, data from the nine groundwater samples collected at IR Site 34 did not exhibit any chemical concentrations exceeding residential PRGs or TPH criteria.</p> <p>Data gaps were identified near former GAPs and near storm sewers that could provide preferential pathways for migration of contaminated groundwater, and a number of sampling locations lacked data for one or more chemicals. In addition, the areas where chemicals were present above PRGs were not adequately defined for the purposes of estimating potential risks to human and ecological receptors.</p>	<p>1) Are there a sufficient quantity and quality of data to support human health and ecological risk assessments?</p> <p>2) Do the estimated risks posed to future, commercial/ industrial workers, construction workers, residents, or recreational users from potential exposures to soil and groundwater at IR Site 34 warrant a FS under CERCLA?</p> <p>3) Do the estimated risks posed to ecological receptors from potential exposures to soil and groundwater at IR Site 34 warrant a FS under CERCLA?</p>	<p><b>Inputs:</b></p> <ul style="list-style-type: none"> <li>Data from previous investigations, including the EBS investigation, that identified arsenic, cadmium, chromium, lead, Aroclor-1254, Aroclor-1260, and PAHs in soil at concentrations exceeding the 1996 PRGs (and background concentrations for metals)</li> <li>Site history and physical features</li> <li>Aerial photographs</li> <li>Geologic and hydrogeologic data</li> <li>Chemical and physical data for soil and groundwater collected during the IR Site 34 RI sampling activities, including metals, VOCs, SVOCs, PAHs, pesticides, PCBs, and TPH in the purgeable and extractable ranges</li> <li>Regulatory agency considerations</li> <li>Physical and chemical properties of identified chemicals</li> <li>Chemical toxicity data</li> <li>Exposure scenarios and pathways for receptors of concern (human and ecological)</li> <li>Results of human health and ecological risk assessments</li> </ul> <p><b>Criteria for Choosing Between Alternative Actions:</b></p> <ul style="list-style-type: none"> <li>Human health and ecological risk assessment criteria</li> <li>Federal regulations</li> <li>CERCLA</li> <li>State regulations</li> <li>California Toxics Rule</li> </ul>	<p>The nominal limits of IR Site 34 will define the lateral boundary for soil samples, plus several step-out samples collected during RI sampling activities. For groundwater, the limits of any groundwater plume (if detected) will define the spatial boundaries. Grab groundwater samples will be limited to the FWBZ and the upper limits of the SWBZ (assumed maximum depth of 65 feet bgs). If wells are needed, one well will assess the vertical extent of contamination. It is anticipated that the extent of groundwater contamination will be within 65 feet of the ground surface.</p> <p><b>Temporal Boundary:</b> The temporal boundaries of the data set extend from the beginning of Navy activities to the date of the most recent collection of field data. Navy activity occurred from the 1940s to 1997. Data were collected from 1994 to 2007.</p> <p>The temporal boundaries of the risk assessment extend from the beginning of Navy activities to an undetermined future time (based on anticipated future use as a recreational site).</p> <p><b>Scale of Decision-Making:</b> <b>Characterization:</b> Consider soil data from the surface to a depth of 8 feet bgs and all of the groundwater data.</p>	<p><b>Decision Rules:</b> <b>1. Data Quality and Quantity</b> There are two parts to the decision on whether there are a sufficient quantity and quality of data to support human health and ecological risk assessments. The first part of this decision was resolved by of the BCT prior to RI fieldwork, and the second part was resolved after the data were collected. The first part of the decision was based on a review of Table 5-1 in the work plan (SulTech 2006), which presents the rationale for selecting the numbers and types of samples to be analyzed at each sampling location. This rationale incorporates the data from previous investigations into a number of professional judgment decisions for collecting additional data in areas where one or more of the following conditions exist: (1) chemical concentrations in previous samples exceeded 1996 PRGs; (2) one or more contamination sources may be present and no samples were collected previously; and (3) previous samples were not analyzed for all chemicals that could have been released. This rationale was designed to maximize the likelihood of detecting chemicals that may have been released to the environment.</p> <p>The second part of this decision will be based on the amounts and quality of usable data that result from the sampling and analyses described in Step 7, as determined by the following rules:</p> <p>1a) If the results of the validation and usability evaluations described in Section 4.0 of the SAP (SulTech 2006) indicate the data are acceptable, then there is a sufficient quality and quantity of data to complete a human health risk assessment and an ecological risk assessment.</p> <p>1b) If the data do not meet the criteria described in (1a) above, then there is not a sufficient quality and quantity of data to complete a human health risk assessment and an ecological risk assessment.</p> <p><b>2. Human Health Risks</b> 2a) If the estimated human health risk exceeds the human health risk criteria (excess cancer risk greater than <math>10^{-6}</math> or noncancer hazard index of 1), an evaluation of remedial alternatives in a FS is warranted.</p> <p>2b) If the estimated human health risk is less than the criteria (excess cancer risk less than <math>10^{-6}</math> or noncancer hazard index of 1), no further action will be recommended.</p>	<p>The baseline condition for IR Site 34 is that chemicals are present in quantities that exceed risk criteria. The alternative condition for IR Site 34 is that chemicals are not present in quantities that exceed risk criteria. Total study error is limited because the sample design includes collecting data in known source areas, which should result in biased high results. This approach will minimize the likelihood of a Type I error, which would falsely reject the baseline condition.</p> <p>Whether the site has been adequately characterized is a yes or no decision; the types and numbers of samples collected at the site should be such that there is a very low probability that the exposure point concentrations used in the risk assessments will underestimate the true concentrations at the site.</p> <p><b>Human Health Risk:</b> Whether a FS will be performed to evaluate remedial alternatives protective of human health is a yes or no decision; EPA guidance and risk assessment provide tolerable limits on error.</p> <p><b>Ecological Risk:</b> Whether a feasibility study will be performed to evaluate remedial alternatives protective of ecological health is a yes or no decision; EPA guidance and risk assessment provide tolerable limits on error.</p> <p>Tolerable errors on analytical results are specified by criteria for measurement quality objectives described in the SAP (SulTech 2006).</p>	<p><b>General Data Collection Design:</b> The sample design for Mobilization 1 will close the identified data gaps by (1) collecting samples on a modified grid and analyzing the samples for a consistent analytical suite, (2) collecting samples beneath and near the fence lines and on a portion of EBS Parcel 16 to assess for PCBs, (3) evaluating the extent of chromium and lead at fixed intervals around buildings that had sandblasting activity using dynamic work strategies associated with real-time measurement, and (4) further delineating areas where metals and PCBs exceeded PRGs during previous sampling events. The sampling results will (1) further delineate areas where previous chemical detections exceeded PRGs, (2) assess identified data gaps (the two GAP sites and the storm drain corridors), and (3) provide adequate characterization of the entire site for the full analytical suite of metals, VOCs, SVOCs, pesticides, PCBs, and TPH. The rationale for each sampling location is presented in Table 5-1 of the SAP (SulTech 2006). The grid will include 12 borings (DP-1, DP-2, DP-5 through DP-8, DP-10, DP-12, DP-13, DP-15, DP-16, and DP-19) advanced to 15 feet bgs that will aid collection of soil samples from ground surface, from 0 to 2 feet bgs, and soil samples from just above shallow groundwater (or a maximum depth of 8 feet bgs), as well as grab groundwater samples from each boring.</p> <p>Five additional borings (DP-3, DP-4, DP-9, DP-11, and DP-14) will be advanced to collect grab samples of shallow groundwater. Two additional borings will be located based on field observations and advanced to 65 feet bgs to assess the vertical extent of groundwater contamination. These two borings will aid collection of soil samples from ground surface, from 0 to 2 feet bgs, soil samples from just above shallow groundwater (or a maximum depth of 8 feet bgs), and shallow and deep grab groundwater samples from each boring. The sample size will be 37 soil samples and 20 grab groundwater samples. Surface soil samples will be analyzed for metals, PAHs, pesticides, and PCBs.</p>

**TABLE 3-1: SITE 34 REMEDIAL INVESTIGATION DQO PROCESS (CONTINUED)**  
 Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

1	2	3	4	5	6	7
State the Problem	Identify the Decisions	Identify Inputs to the Decisions	Define Study Boundaries	Develop Decision Rules	Specify Tolerable Limits on Error	Optimize Sampling Design
<p>The extent of soil containing metals and PCBs concentrations exceeding PRGs is not known. Soil below the northern and western fence lines may have had PCB-containing oil applied for weed control, and the condition of the soil is not fully evaluated. The soils around each building where sandblasting occurred have only had limited evaluations for paint wastes. PCBs may be present in soil at EBS Parcel 16 that may affect Site 34.</p> <p>While there were no documented releases, the potential primary chemical release mechanisms at IR Site 34 include direct discharges to the storm sewers (prior to the early 1970s), and spills and leaks to the soil. These primary releases may have been followed by potential secondary and tertiary releases: (1) to soils by exfiltration from storm drains; (2) to storm drains by overland flow to catchments or infiltration from soil and groundwater; (3) to groundwater from soil or storm drains; and (4) to surface water and sediments from storm drains, groundwater flow, or overland flow. Migration of chemicals along fuel line or storm sewer bedding material (if present) also may occur. Chemicals sorbed to surface soils may also be transported by the wind.</p> <p>A preliminary CSM has been developed and is presented in RI Work Plan (SulTech 2006). The CSM illustrates that terrestrial ecological receptors could be exposed to soils at IR Site 34, and that marine ecological receptors in the Oakland Inner Harbor could be exposed to groundwater and storm drain discharges from the site. Therefore, it is important to evaluate the potential risks to these ecological receptors. In addition, the CSM incorporates current and future site use information, and documents the potential for exposures of future human receptors, including commercial/industrial workers, construction workers, residents, and recreational users, to on-site soils.</p> <p>IR Site 34 currently is unoccupied land that is planned for recreational reuse as a golf course. However, the Navy will be prepared for potential changes to those site use plans by evaluating potential risks to future commercial/industrial workers, construction workers, and residents, in addition to the potential risks to recreational users. The DQOs described in this table are applicable to all future reuses.</p>	(see above)	(see above)	<p><u>Human Health Risk Assessment:</u></p> <p>Soil from the surface to 2 feet bgs and from the surface to 4 feet bgs (the depth at which groundwater was encountered during RI sampling activities) will be considered for scenarios that involve commercial/industrial workers, construction workers, and residents. Recreational scenarios will involve only the first 2 feet of soil. The site will be considered one exposure area.</p> <p>Groundwater as drinking water will not be considered a complete pathway.</p> <p><u>Ecological Risk Assessment:</u></p> <p>Soil from 0 to 4 feet bgs will be evaluated for risk to terrestrial ecological receptors. Potential contribution of groundwater chemicals to marine ecological receptors in Oakland Inner Harbor also will be considered.</p>	<p>2c) If the risk is within the risk management range, a risk management decision will be made by the BCT.</p> <p><u>Action Levels:</u></p> <ul style="list-style-type: none"> <li>Target excess cancer risk level of 10<sup>-6</sup></li> <li>Hazard index of 1 (total or segregated)</li> <li>Blood-lead levels of 10 micrograms per deciliter</li> <li>Decisions about site risk will be based on the 95 percent upper confidence limit of concentrations of chemicals of interest.</li> </ul> <p><b>3. Ecological Risks</b></p> <p>3a) If chemical concentrations result in a hazard index greater than 1, or if chemical concentrations in groundwater are anticipated to exceed NAWQC at the point of exposure, remedial action will be considered in a FS.</p> <p>3b) If chemical concentrations do not result in a hazard index greater than 1, or if chemical concentrations in groundwater are not anticipated to exceed NAWQC, no remedial action for ecological exposure will be considered.</p> <p><u>Action Levels:</u></p> <ul style="list-style-type: none"> <li>Hazard index of 1 (total or segregated)</li> <li>California Toxics Rule</li> <li>San Francisco Bay Basin Plan</li> <li>NAWQC (EPA 2002a, 2002b)</li> </ul>	(see above)	<p>All other samples from these borings will be analyzed for metals, VOCs, SVOCs, PAHs, pesticides, PCBs, and TPH in the purgeable and extractable ranges.</p> <p>Additional shallow soil samples will be collected at fixed intervals below fence lines and around buildings associated with sandblasting activities, and on a portion of adjacent EBS Parcel 16 to assess the potential presence of metals and PCBs. In addition, the extent of paint waste contamination will be evaluated by using dynamic work strategies associated with real-time measurement of chromium and lead in soil. These metals were detected in soil containing metals at concentrations exceeding PRGs at IR Site 34. Sampling and analysis will be conducted using a logic progression described in Section 5.1 of the RI Work Plan (SulTech 2006).</p> <p>If appropriate, Mobilization 2 will include installation of four shallow and one deep (to a maximum depth of 65 feet bgs) groundwater monitoring wells. Ten soil samples will be collected during this effort (at 0 to 2 feet bgs and 2 to 8 feet bgs), and four quarters of groundwater sampling will be performed.</p> <p><u>Design Optimization:</u></p> <p>If grab groundwater concentrations are above the criteria for groundwater (see Section 5.1 of the RI Work Plan [SulTech 2006]), then mobilization 2 will be necessary to install monitoring wells to collect additional data for the risk assessments. Mobilization 2 will include installation of four shallow and one deep (to a maximum depth of 65 feet bgs) groundwater monitoring wells. During this effort, a total of 10 soil samples will be collected, and will include 1 sample at 0 to 2 feet bgs and 1 sample at 2 to 8 feet bgs from each well boring. In addition, four quarters of groundwater samples will be collected from each of the newly installed wells.</p>
<b>Problem Statement:</b>	(see above)	(see above)	(see above)	(see above)	(see above)	(see above)
<p>Historical activities at IR Site 34 resulted in the release of at least four metals and two organic chemicals that were detected in site soil at concentrations exceeding PRGs (and the background concentrations of the metals). These activities may have caused other chemical releases. In addition, sample results and previous activity on a portion of EBS Parcel 16 suggest a release of PCBs. Results of previous sampling were not sufficient to provide reliable estimates of the potential risks posed to human or ecological receptors.</p>

- Notes: All results are in milligrams per kilogram.  
 For samples with less than 15 percent censored data, one-half the reporting limit is substituted for each nondetect measurement in all calculations.  
 For higher frequencies of censored data, all calculations were performed using stochastic modeling, following the "bounding" approach from EPA (2002c), as described below under notes c and d.  
 No calculations of the mean, SD, CV, or UCL95 are performed for sample sizes less than three or detection frequencies of zero.
- a For all cases with at least five detected samples and a detection frequency greater than or equal to 50 percent, tested using the Shapiro-Wilk W test (alpha equal to 0.05).  
 Distributions confirmed as normal or lognormal are listed as "Normal" or "Lognormal." For cases where distribution testing was not conducted, the distribution is listed as "Not Tested."  
 For cases in which distributions could not be confirmed using the Shipiro-Wilk W test, distributions were estimated using probability plots, box plots, and frequency histograms.  
 Distributions estimated to be normal or lognormal are listed as Unknown[a] or Unknown[b], respectively.
- b Estimated for all samples using a nonparametric approach, based on rank ordering of the data (reported values used for all censored data).
- c For all samples with at least one detection, calculated using distribution-dependent formulae.  
 For confirmed or estimated normal distributions with fewer than 15 percent censored data, calculated using equations 4.3 (mean) and 4.4 (standard deviation) in Gilbert (1987).  
 For confirmed or estimated lognormal distributions with fewer than 15 percent censored data, these are the MVUEs following equations 13.3 (mean) and 13.5 (standard deviation) in Gilbert (1987).  
 All other calculations use the median values generated from 2,000 iterations of a Monte Carlo model, following the "bounding" approach described in EPA (2002c) [see conceptual model on Figure 2-6 and text in methods section for more details].
- d For metals with only detected results, methods followed EPA (2002c, 2004a). For metals with at least one censored result, methods followed recommendations in EPA (2006).

**TABLE 3-2: SUMMARY OF DESCRIPTIVE STATISTICS FOR THE PINK BACKGROUND DATA SET (CONTINUED)**

Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Method (Statistic) Codes for calculating the 95UCL are defined as follows

(1)	Maximum detected concentration
(2)	95 percent UCL calculated using Student's <i>t</i> distribution
(3)	95 percent UCL calculated using Land's H statistic
(4), (5), (6)	95, 97.5, or 99 percent UCL, respectively, calculated using the nonparametric Chebyshev method
(7), (8), (9)	95, 97.5, or 99 percent UCL, respectively, calculated using the MVUE Chebyshev method
(10)	95 percent UCL calculated using the approximate gamma method
(11)	95 percent UCL calculated using the adjusted gamma method
(12)	95 percent UCL calculated using the KM mean and Student's <i>t</i> cutoff for the UCL
(13), (14), (15)	95, 97.5, or 99 percent UCL, respectively, calculated using the KM mean and the nonparametric Chebyshev method to estimate the UCL
(16)	95 percent UCL calculated using the KM mean and a percentile bootstrap to estimate the UCL
(17)	95 percent UCL calculated using the KM mean and a BCa bootstrap to estimate the UCL
EPA	U.S. Environmental Protection Agency
KM	Kaplan-Meier product limit estimator
CV	Coefficient of variation (SD/mean)
Max	Maximum concentration reported
Min	Minimum concentration reported
MVUE	Minimum variance unbiased estimator
N/A	Not applicable
NE	Not estimable using the KM
Q95	95th percentile (quantile)
SD	Standard deviation
95UCL	The one-sided 95 percent upper confidence limit of the mean. Following EPA (2004a, 2006) this can be estimated using either a 95, 97.5, or 99 percent UCL.
Unknown[a]	Distribution assumed to be normal based on examination of probability plots and outlier box plots
Unknown[b]	Distribution assumed to be lognormal based on examination of probability plots and outlier box plots

- Notes: All results are in micrograms per liter.
- For samples with less than 15 percent censored data, one-half the reporting limit is substituted for each nondetect measurement in all calculations.
- For higher frequencies of censored data, all calculations were performed using stochastic modeling, following the "bounding" approach from EPA (2002), as described below under notes c and d.
- No calculations of the mean, SD, CV, or UCL95 are performed for sample sizes less than three or detection frequencies of zero.
- a For all cases with at least five detected samples and a detection frequency greater than or equal to 50 percent, tested using the Shapiro-Wilk W test (alpha equal to 0.05). Distributions confirmed as normal or lognormal are listed as "Normal" or "Lognormal." For cases where distribution testing was not conducted, the distribution is listed as "Not Tested." For cases in which distributions could not be confirmed using the Shapiro-Wilk W test, distributions were estimated using probability plots, box plots, and frequency histograms. Distributions estimated to be normal or lognormal are listed as Unknown[a] or Unknown[b], respectively.
- b Estimated for all samples using a nonparametric approach, based on rank ordering of the data (reported values used for all censored data).
- c For all samples with at least one detection, calculated using distribution-dependent formulae.
- d For confirmed or estimated normal distributions with fewer than 15 percent censored data and for distributions listed as "Not Tested," calculated using equations 4.3 (mean) and 4.4 (standard deviation) in Gilbert (1987). For confirmed or estimated lognormal distributions these are the MVUEs, following equations 13.3 (mean) and 13.5 (standard deviation) in Gilbert (1987). For samples with greater than 15 percent censored data, these are the median values generated from 2,000 iterations of a Monte Carlo model, following the "bounding" approach described in EPA (2002). [see conceptual model on Figure 2-6 and text in methods section for more details].
- d For confirmed or estimated normal distributions, calculated using equation 11.6 in Gilbert (1987). For confirmed or estimated lognormal distributions with no more than 15 percent censored data, calculated using Land's method (EPA 1992; Gilbert 1987). For confirmed or estimated lognormal distributions with greater than 15 percent censored data, calculated using the MVUE Chebyshev method (EPA 2002). For samples with greater than 15 percent censored data and distributions listed as "Not Tested," calculated using the nonparametric Chebyshev method. Calculations for all cases with greater than 15 percent censored data use the 95th percentile generated from 2,000 iterations of a Monte Carlo model, following the "bounding" approach, described in EPA (2002) [see conceptual model on Figure 2-6 and text in methods section for more details].
- CV Coefficient of variation (SD/mean) MVUE Minimum variance unbiased estimator SD Standard deviation
- Min Minimum concentration reported N/A Not applicable UCL<sub>95</sub> The one-sided 95 percent upper confidence limit of the mean
- Max Maximum concentration reported Q95 95th percentile (quantile) Unknown[a] Distribution assumed to be normal based on examination of probability plots and outlier box plots
- Unknown[b] Distribution assumed to be lognormal based on examination of probability plots and outlier box plots

## 4.0 NATURE AND EXTENT OF CONTAMINATION

This section summarizes the analytical data collected during environmental investigations at IR Site 34 and describes the nature and extent of contamination in soil and groundwater. For the nature and extent discussion, contamination at IR Site 34 is defined as a chemical concentration exceeding the comparison criteria listed in Section 3.3. However, a determination of whether chemicals are likely to pose risk to human health and/or the environment and require further consideration in an FS is based on the risk assessments presented in Section 6.0 and 7.0. NAS Alameda was closed in 1997 and most of the infrastructure at IR Site 34 has since been removed. Sources that may have released chemicals to soil and groundwater at IR Site 34 are no longer believed to remain on site; continued releases associated with historical operations are unlikely.

### 4.1 NATURE AND EXTENT OF SOIL CONTAMINATION

During the environmental investigations described in Section 1.3.4, 208 soil samples (including six field duplicates and one sediment sample) were collected at IR Site 34 and analyzed for the analytical groups listed in Table 1-2. Soil sampling locations are shown on Figure 1-4. Table 4-1 provides a statistical summary for analytical results of soil samples at IR Site 34. The table lists all chemicals that were detected in soil samples from IR Site 34, and identifies those chemicals that exceeded comparison criteria (and background concentrations for metals).

#### 4.1.1 Metals in Soil

Laboratory analysis of 105 soil samples from IR Site 34 for 24 metals shows that 6 metals (arsenic, cadmium, chromium, iron, lead, and vanadium) are present in one or more soil samples at concentrations above the EPA or California-modified residential PRGs (see Table 4-1). Each of these six metals is discussed below. Table 4-1 also shows beryllium is the only metal with background data that was not detected above the upper bound (95 percentile) of the background distribution; molybdenum, selenium, and thallium are not associated with Pink Fill Area background data. Further evaluations indicated the distribution of 18 metals (aluminum, antimony, arsenic, barium, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, nickel, potassium, sodium, vanadium, and zinc) is different at IR Site 34 than in the Pink Fill Area, as shown in Table 4-2 and Appendix G. Statistical analysis determined that beryllium, mercury, and silver are not distributed differently at IR Site 34 than in the background area (see Table 4-2). The highest concentrations of most metals were detected near former Buildings 331, 343, 344, and in the northwest corner of IR Site 34. Concentrations of the 18 metals detected above background concentrations are generally distributed across IR Site 34, as shown for individual metals on Figures 4-1 through 4-5.

Arsenic was detected in soil samples from IR Site 34 above the background concentration (9.14 mg/kg) in 12 of 105 samples and above the California-modified residential PRG (0.062 mg/kg) and industrial PRG (0.25 mg/kg) in 98 samples. Note that the background concentration of arsenic in the Pink Fill Area is two orders of magnitude higher than the California-modified residential PRG. The 95UCL of the average arsenic concentration (13 mg/kg) in soil samples at IR Site 34 is greater than the background concentration in the Pink

Fill Area. Arsenic concentrations above the background concentration were generally located near the former railroad track and the former buildings in the northeast quadrant of IR Site 34. The three highest concentrations of arsenic (120 mg/kg at location HS1N, 62 mg/kg at location DP12, and 52.1 mg/kg at location 018-007-034) were detected in samples collected between 1.5 and 2.5 feet bgs. Lower concentrations of arsenic in surface samples collected at locations HS1N (estimated 5.3 mg/kg) and DP12 (6.9 mg/kg) suggest that the highest arsenic concentrations are not related to contamination at the ground surface. Although a source of subsurface arsenic contamination at locations HS1N and DP12 was not apparent, some of the arsenic detected may have resulted from dissolution of paint chips, paint dust, pesticides, and treated wood that were generated during historical operations at the site. However, sources related to historical operations at IR Site 34 are no longer believed to remain on site. Sampling locations where arsenic concentrations in soil exceeded comparison criteria are shown on Figure 4-1.

Cadmium was detected in soil samples from IR Site 34 above the background concentration (1.72 mg/kg) in 41 of 105 samples. Sample 018-0026 collected at location 018-006-026 exhibited cadmium at an estimated concentration of 45.8 mg/kg, which exceeds the EPA residential PRG (37 mg/kg). Sample 18-0026 was collected within 6 inches of the ground surface near the former railroad track in the northwest corner of the site. The average cadmium concentration (4.3 mg/kg) detected in soil samples from IR Site 34 and the 95UCL of the average cadmium concentration (8.9 mg/kg) are well below the residential PRG. Sampling locations where cadmium concentrations in soil exceeded comparison criteria are shown on Figure 4-22.

Chromium was analyzed for in soil samples from IR Site 34 using an XRF field screening unit and at a fixed laboratory. The XRF detection limit for chromium was above the background concentration (54.8 mg/kg). XRF screening results for 106 soil samples suggested chromium concentrations in soil exceeded the EPA residential PRG (210 mg/kg) at 36 locations across IR Site 34. Most of these exceedances were around the perimeter of former buildings, particularly Buildings 331, 343, 344, 475, 510, and 604 (see Figure 4-2). XRF results are screening-level data that have a high bias when qualitatively compared with results from fixed-laboratory analysis (see Section 3.3). For this reason, sampling locations where XRF field screening identified concentrations above the PRG are identified with purple circles on Figure 4-2, but numerical results are not shown. Numerical results for XRF field screening are presented in Appendix D.

Results of fixed-laboratory analysis indicated concentrations of chromium (total) exceeded the background concentration (54.8 mg/kg) in 37 of 105 samples, exceeded the EPA residential PRG (210 mg/kg) in 5 samples, and exceeded the EPA industrial PRG (450 mg/kg) in 1 sample. Two additional samples exhibited chromium at the same concentration as the EPA residential PRG. Twenty-four samples were analyzed at a fixed laboratory for hexavalent chromium. Concentrations in each sample were below the detection limit (0.05 to 0.06 mg/kg); the EPA residential PRG for hexavalent chromium is 30 mg/kg. Three of the samples that contained chromium (total) at or above the PRG were collected near the southeast corner of former Building 343. Two samples collected above the storm sewer near the northeast site boundary

also exhibited chromium concentrations at or above the PRG. The highest chromium concentration (550 mg/kg at location DP02) was detected in a sample collected near the southwest corner of the site. All seven samples exhibiting chromium concentrations at or above PRGs were collected within 6 inches of the ground surface. Sampling locations where chromium concentrations in soil exceeded comparison criteria are shown on Figure 4-2. The average chromium concentration (68 mg/kg) detected in soil samples from IR Site 34 and the 95UCL of the average chromium concentration (97 mg/kg) are well below the residential PRG (210 mg/kg).

Iron was detected in soil samples from IR Site 34 at concentrations exceeding the background concentration (22,280 mg/kg) and the EPA residential PRG (23,000 mg/kg) in 21 of 82 samples, and above the EPA industrial PRG (100,000 mg/kg) in 2 samples. These exceedances appeared to be clustered (1) near the former railroad track at the northwest corner of the site, (2) near the southeast corner of former Building 343 and the northeast corner of former Building 344, (3) near the former railroad tracks south of former Building 331, and (4) above the storm sewer near the northeast site boundary. The two highest concentrations of iron (180,000 mg/kg at location HS2A and 120,000 mg/kg at location HS2W) were in samples collected near the northeast corner of former Building 344. The average iron concentration (23,524 mg/kg) detected in soil samples from IR Site 34 and the 95UCL of the average iron concentration (35,358 mg/kg) exceed the residential PRG (23,000 mg/kg). However, removing the two highest concentrations from the calculation reduces the average iron concentration (20,252 mg/kg) and the 95UCL of the average concentration (22,515 mg/kg) below the residential PRG. Iron was detected at concentrations exceeding PRGs in samples from multiple depth intervals. Results of iron analysis appear to show a few localized areas of soil contamination extending as far as 7 feet bgs. Sampling locations where iron concentrations in soil exceeded comparison criteria are shown on Figure 4-3.

Lead was analyzed for in soil samples from IR Site 34 using an XRF field screening unit and at a fixed laboratory. XRF screening results for 106 soil samples suggested lead concentrations in soil exceeded the background concentration (29.7 mg/kg) in 44 samples and the California-modified residential PRG (150 mg/kg) in 17 samples. Most of these exceedances were in the northwest corner of the site, south of former Building 331, and near former Buildings 343, 344, and 475 (see Figure 4-4). XRF results are screening-level data that have a high bias when qualitatively compared with results from fixed-laboratory analysis (see Section 3.3). For this reason, sampling locations where XRF field screening identified concentrations above the PRG are identified with gray circles on Figure 4-4, but numerical results are not shown. Numerical results for XRF field screening are presented in Appendix D.

Results of fixed-laboratory analysis indicated concentrations of lead exceeded the background concentration (29.7 mg/kg) in 48 of 105 samples, the California-modified residential PRG (150 mg/kg) in 29 samples, and the EPA industrial PRG (800 mg/kg) in 7 samples. These exceedances appeared to be present in a number of clusters (1) near the former railroad track at the northwest corner of the site; (2) around former Buildings 331, 343, 344, and 475; (3) above the storm sewer near the northeast site boundary; and (4) in isolated locations at the southwest corner of the site. The two highest concentrations of lead (21,000 and 18,000 mg/kg) were in

samples from two depth intervals at DP16 at the northeast corner of former Building 331. Former Buildings 343, 475, and 510 were reportedly used for sandblasting; lead in soil is likely related to chips of lead-based paint released during historical operations. Lead concentrations exceeding PRGs generally occurred in soil within 2 feet of the ground surface. Sampling locations where lead concentrations in soil exceeded comparison criteria are shown on Figure 4-4.

Vanadium was detected in soil samples from IR Site 34 at concentrations exceeding the background concentration (47.3 mg/kg) in 8 of 105 samples and the EPA residential PRG (78 mg/kg) in 4 samples. These exceedances were found (1) near the southwest and southeast corners of former Building 343, (2) near the northeast corner of former Building 344, and (3) near the southwest corner of former Building 331. A vertical pattern of vanadium dispersal was not apparent. The four samples exhibiting vanadium concentrations above the residential PRG were collected from different depths (less than 0.5 to 7 feet bgs), and samples from overlying and underlying intervals showed lower concentrations of vanadium. The average vanadium concentration (32 mg/kg) detected in soil samples from IR Site 34 and the 95UCL of the average vanadium concentration (35 mg/kg) are less than half of the residential PRG (78 mg/kg). Sampling locations where vanadium concentrations in soil exceeded comparison criteria are shown on Figure 4-5.

Of the six metals discussed above, only arsenic, iron, and lead showed patterns of site-wide contamination. Cadmium, chromium, and vanadium were detected above PRGs in less than 5 percent of the samples, or at concentrations less than three times the PRGs. The 95UCLs of the average concentration for cadmium, chromium, and vanadium were well below their respective residential PRGs. The 95UCL of the average concentration for iron is also below the PRG when two extreme concentrations (180,000 mg/kg and 120,000 mg/kg; both in shallow soil at the northeast corner of former Building 344) are removed from the statistical calculation. Metals concentrations above PRGs are generally localized to several defined areas. The lateral and vertical extent of metals contamination in soil appears to be sufficiently characterized.

#### **4.1.2 Volatile Organic Compounds in Soil**

Analysis of soil samples shows that 17 VOCs were detected in soil at IR Site 34. However, only one VOC (1,4-dichlorobenzene [-DCB] at a concentration of 6.8 mg/kg) in only one sample (0.5 to 0.9 feet bgs at location DP02 at the southwest corner of the site) exceeded the residential PRG (3.5 mg/kg), and the magnitude of the exceedance was only two times greater than the PRG. In addition, as summarized in Table 4-1, 13 of the 17 VOCs were only detected once; 2-butanone and carbon disulfide were detected twice and methylene chloride and toluene were detected three times. Naphthalene was detected in one soil sample by VOC analysis. Naphthalene was also analyzed in the SVOC and PAH analytical suites and is discussed in Section 4.1.4. VOCs were detected at ten locations dispersed around IR Site 34, including:

- 018-003-013 at the southeast corner of former Building 474 (also the northeast corner of former Building 477)

- 018-003-014 at the northeast corner of former Building 476
- 018-003-015 at the southeast corner of former Building 476
- DP02 at the southwest corner of the site (11 detections)
- DP16 at the northeast corner of former Building 331 (1 detection)
- DP17 above the storm sewer near the northeast site boundary (1 detection)
- MW-20 south of IR Site 34 near the southwest corner of the site (2 detections)
- MW-23 west of IR Site 34 north of the former railroad tracks (1 detection)
- MW-24 at the northwest corner of the site (2 detections)
- AA-IT001-01 (sediment sample) from a storm drain catch basin near the southeast corner of former Building 330 (2 detections) (sediment has since been removed)

Based on these results, VOCs appear to be present in soil only in isolated areas and do not represent site-wide contamination. The lateral and vertical extent of VOC contamination in soil appears to be sufficiently characterized.

#### **4.1.3 Semivolatile Organic Compounds in Soil**

Analysis of soil samples shows that 28 SVOCs were detected in soil samples from IR Site 34. Sixteen of the detected SVOCs are PAHs, including all five chemicals detected at concentrations exceeding residential PRGs. As a result, these PAH findings are discussed separately in Section 4.1.4. Table 4-1 shows that 9 of the remaining 12 SVOCs were detected only once in soil samples from IR Site 34. Dibenzofuran was detected twice, di-n-Butylphthalate was detected four times, and bis(2-ethylhexyl)phthalate was detected five times. SVOCs were detected at 11 locations around IR Site 34, including:

- 004-003-008 on the south side of former Building 331 (one detection)
- 018-004-020 on the west boundary of the site (one detection)
- 018-004-021 over the storm sewer in the west-central portion of the site (one detection)
- 018-004-022 near the southwest corner of the site (one detection)
- 018-004-023 near the southwest corner of the site (four detections)
- 018-007-035 near the northeast corner of former Building 476 (three detections)
- DP10 south of former Building 475 and west of former Building 344 (one detection)

- DP16 at the northeast corner of former Building 331 (three detections)
- MW-20 south of IR Site 34 near the southwest corner of the site (one detection)
- MW-23 west of IR Site 34 north of the former railroad tracks (one detection)
- AA-IT001-01 (sediment sample) from a storm drain catch basin-near the southeast corner of former Building 330 (three detections) (sediment has since been removed)

Based on these results, SVOCs appear to be present in soil only in isolated areas and do not represent site-wide contamination. More than 50 percent of the highest concentrations of SVOCs were detected in a sample from location DP16. This sample was collected above a layer of black clayey sand with a strong diesel odor that was identified from 2.75 to 3.75 feet bgs (see the boring log in Appendix B). Similar material was not noted in other soil borings; the material does not appear to represent site-wide conditions or a large mass of contaminated media. The lateral and vertical extent of SVOC contamination in soil appears to be sufficiently characterized.

#### 4.1.4 Polycyclic Aromatic Hydrocarbons in Soil

Analysis of soil samples shows that 18 PAHs were detected in soil samples from IR Site 34, as summarized in Table 4-1. PAH contamination was evaluated relative to B(a)P-equivalents. Several samples were analyzed for PAHs by more than one analytical method. In these cases, results from the analytical method with the lowest detection limit (EPA Method 8260c-SIM) were used in the B(a)P-equivalent evaluation. Table 4-3 presents the EPA and OEHHHA B(a)P-equivalents for each of the 54 individual samples and also presents the site-wide averages. Figure 4-6 shows the locations of the 54 samples and also provides the EPA B(a)P-equivalent concentration for each of the samples. Only five of the 54 individual samples exhibited total B(a)P-equivalent concentrations above the comparison criterion of 0.62 mg/kg, and they are summarized in the table below.

**Samples with Total B(a)P-Equivalent Concentrations Exceeding Comparison Criterion**

Sample Location Number	Sample Identification Number	Sample Depth (feet bgs)	EPA B(a)P Equivalent (mg/kg)	OEHHA B(a)P Equivalent (mg/kg)
004-003-008	004-0012	5 – 6	1.3	1.4
DP06	105-S34-017	0 – 0.5	1.2	1.3
DP10	105-S34-031	1.5 – 2	2.9	3.1
DP16	105-S34-046	0 – 0.5	8.4	9.5
DP16	105-S34-047	1.5 – 2	0.99	1.1
Site-Wide Average B(a)P-Equivalent Concentration			0.47	0.52

The site-wide average EPA and OEHHHA B(a)P-equivalent concentrations (0.47 mg/kg and 0.52 mg/kg, respectively) are below the established screening level of 0.62 mg/kg. The site-wide

average concentration is influenced by an EPA B(a)P-equivalent value of 8.4 mg/kg and an OEHHA B(a)P-equivalent value of 9.5 mg/kg in a sample of anomalous soil collected above a black clayey sand with a strong diesel odor at location DP16. The site-wide average EPA and OEHHA B(a)P-equivalent concentrations without this sample are 0.23 mg/kg and 0.25 mg/kg, respectively. Elevated concentrations of PAHs were confined to individual sample locations and do not appear to represent large masses of contaminated media. The lateral and vertical extent of PAH contamination in soil appears to be sufficiently characterized.

#### **4.1.5 Pesticides in Soil**

Analysis of 95 soil samples shows that 20 pesticides were detected in soil samples from IR Site 34, as summarized in Table 4-1. Two of the 20 detected pesticide concentrations exceeded EPA PRGs, as discussed in the paragraphs below. Sampling locations where pesticide concentrations in soil exceeded comparison criteria are shown on Figure 4-7.

Dieldrin was detected in 14 of 95 samples at concentrations ranging from 0.0024 to 0.5 mg/kg. Concentrations of dieldrin in three samples exceeded the EPA residential PRG (0.03 mg/kg) and EPA industrial PRG (0.11 mg/kg). All three exceedances were in surface soil samples collected along the fence line at the western site boundary (locations FS7, FS9, and FS10).

Heptachlor epoxide was detected in 14 of 95 samples at concentrations ranging from 0.00077 to 0.11 mg/kg. Concentrations of heptachlor epoxide in three samples exceeded the EPA residential PRG (0.053 mg/kg). All three exceedances were in surface soil samples collected along the fence line at the western site boundary (locations FS9, FS10, and HS7N).

Pesticide contamination in soil at IR Site 34 appears to be limited to the top 6 inches of soil in isolated areas along the fence line at the western site boundary. The lateral and vertical extent of pesticide contamination in soil appears to be sufficiently characterized.

#### **4.1.6 Polychlorinated Biphenyls in Soil**

Analysis of 143 soil samples shows that four PCBs (Aroclor-1248, Aroclor-1254, Aroclor-1260, and Aroclor-1268) were detected in 3, 39, 78, and 26 of 143 soil samples from IR Site 34, as summarized in Table 4-1. All four Aroclors were detected at concentrations ranging from 0.0058 to 11 mg/kg. Concentrations equaled or exceeded the EPA residential PRG (0.22 mg/kg) in two samples (Aroclor-1248 and Aroclor-1268), in 16 samples (Aroclor-1254), and in 22 samples (Aroclor-1260). Concentrations exceeded the EPA industrial PRG (0.74 mg/kg) in one sample (Aroclor-1248) and four samples (Aroclor-1254 and Aroclor-1260). These exceedances were clustered along the eastern site boundary near the former TSTA, between former Buildings 343 and 344 that previously contained transformers and used lubricating oils, on the north and south sides of former Building 331 that previously contained a transformer and used oils and solvents for woodwork, and near the railroad. Isolated exceedances also were identified at former Building 604 that used petroleum oils for air compressors and in off-site step-out samples near former Building 345. Most of the PCB concentrations detected above PRGs were in

samples collected within 0.5 feet of the ground surface, which is consistent with these types of uses. There was no evidence of a release to the surface soils near the transformers during base operations or during the EBS, and many of the transformers were located on concrete slabs that would prevent any releases to subsurface soils. Therefore, specific samples were not collected at previous transformer locations for analysis of PCBs. PCB concentrations were detected above PRGs deeper than 0.5 feet bgs in the following samples: a sample from 0.5 to 0.9 feet bgs at DP02 (Aroclor-1254 and Aroclor-1260) located within the TSTA, a sample from 0.5 to 1.0 feet bgs at 004-Z03-004 (Aroclor-1260) located north of Building 331, and a sample from 2.0 to 2.5 feet bgs at HS1N (Aroclor-1260) located in the northwest corner of the site. Sampling locations where PCB concentrations in soil exceeded comparison criteria are shown on Figures 4-8 through 4-11. Based on these results, the lateral and vertical extent of PCB contamination in soil appears to be sufficiently characterized.

#### 4.1.7 Total Petroleum Hydrocarbons in Soil

Sixty-four soil samples from IR Site 34 were analyzed for total petroleum hydrocarbons as diesel, gasoline, or motor oil, as summarized in Table 4-1. Several of the 64 samples were not analyzed for all three petroleum hydrocarbon ranges, which is why different numbers of analyses are listed for each component in Table 4-1. Diesel- and motor oil-range petroleum hydrocarbons were detected at concentrations exceeding comparison criteria, as discussed in the paragraphs below. Gasoline-range petroleum hydrocarbons were not detected in soil samples from IR Site 34 at concentrations exceeding the comparison criterion.

TPH as diesel was detected in 33 of 56 samples at concentrations ranging from 0.48 to 18,000 mg/kg. Concentrations exceeded the Water Board residential ESL (100 mg/kg) in 10 samples and the Water Board industrial ESL (500 mg/kg) in 6 samples. Four of the samples with exceedances, including the two highest concentrations (18,000 mg/kg at location 004-002-003 and 8,900 mg/kg at location 018-001-007), were collected near former ASTs. The other six samples with exceedances were collected (1) at the northeast corner of former Building 331, (2) the east side of former Building 604, (3) near the northwest and southwest corners of the site, and (4) west of IR Site 34 north of the former railroad tracks. Most of the samples with exceedances were collected within 1 foot of the ground surface. However, samples from two depths at location MW-24 at the northwest corner of the site showed the diesel concentration increased from 0.63 mg/kg near the surface to 2,200 mg/kg between 3 and 4 feet bgs. Elevated concentrations of diesel at locations DP06 and DP16 were detected in samples collected between 1.5 and 2.5 feet bgs. Sampling locations where TPH as diesel concentrations in soil exceeded comparison criteria are shown on Figure 4-12.

TPH as motor oil was detected in 35 of 48 samples at concentrations ranging from 3 to 47,000 mg/kg. Concentrations exceeded the Water Board residential ESL (500 mg/kg) in 14 samples and the Water Board industrial ESL (1,000 mg/kg) in 13 samples. Six of the samples with exceedances were collected near former ASTs. The other eight samples with exceedances were collected at (1) the north side of former Building 330, (2) the southwest corner of former Building 331, (3) the east side of Building 604, and (4) three locations along the western boundary of the site. All of the samples with exceedances were collected within 1 foot of the

ground surface, except for a sample collected between 2 and 2.5 feet bgs in the northwest corner of the site (location DP06). Sampling locations where TPH as motor oil concentrations in soil exceeded comparison criteria are shown on Figure 4-13.

TPH concentrations detected above ESLs were found at several locations across IR Site 34. Thirteen of the 18 samples that contained TPH concentrations above ESLs were collected during April 1995 during the Phase 2A EBS investigation. All of the soil samples from the EBS investigation were collected from surface soils that were stained or suspected of being contaminated, including soil near five ASTs that have since been removed. The lateral extent of TPH contamination in soil appears to be sufficiently characterized. TPH contamination is generally limited to the top 1 foot of soil. However, existing data do not define the maximum depth of motor oil contamination at location DP06 and diesel contamination at locations DP06, DP16, and MW-24.

#### 4.1.8 Summary of Contamination in Soil

For the purposes of this RI, contamination is defined as a chemical detected in an environmental sample at IR Site 34 at a concentration exceeding comparison criteria. Metals, VOCs, PAHs, pesticides, PCBs, and TPH were detected at concentrations above comparison criteria in soil samples collected at IR Site 34. Only the following seven chemicals were detected above comparison criteria in more than 10 percent of the samples:

- Metals (arsenic, iron, lead)
- PCBs (Aroclor-1254, Aroclor-1260)
- TPH (as diesel, as motor oil)

Although PAHs were detected above comparison criteria in less than 10 percent of the samples and the evaluation of PAHs relative to B(a)P equivalents showed the site-wide average B(a)P equivalent concentration is below the comparison criteria of 0.62 mg/kg, the site-wide average concentration is influenced by an EPA B(a)P-equivalent value of 8.4 mg/kg and an OEHHA B(a)P-equivalent value of 9.5 mg/kg in a sample of anomalous soil collected above a black clayey sand with a strong diesel odor at location DP16 (north of Building 331).

In addition to exceeding comparison criteria in more than 10 percent of the samples, these seven chemicals, and the following additional chemicals were determined to likely pose potential risk, based on a residential exposure (see the HHRA, Section 6.0)

- PCBs (Aroclor-1248, 1268)
- Pesticides (dieldrin, heptachlor epoxide),
- SVOC (naphthalene)

- VOCs (1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and 1,4-DCB)

After taking into consideration that further evaluation in an FS is based on the risk assessments and reviewing the distribution of concentrations for those chemicals driving risk, residual soil contamination appears to be collocated and limited to six specific areas of concern at IR Site 34 (AOC). The list below (as shown on Figure 4-14) indicates which chemicals are present at each AOC at concentrations potentially posing risk and the likely historical sources of the contaminants.

- **Northwest corner of the site, near the former railroad and former Building 510:** arsenic, PCBs, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to use and subsequent fill of the historical railroad and historical sandblasting in former Building 510. Oils and solvents may have been released from sandblasting equipment.
- **North of Building 331:** arsenic, lead, PCBs, naphthalene, and TPH as diesel. Residual contamination in this area appears to be related to use of oils and solvents for woodwork at the former building and metal working at Building 330 to the west.
- **Along the former railroad and south of former Building 331:** lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to use and subsequent fill of the historical railroad, historical releases from former AST 331, and use of oils and solvents for woodwork at the former building.
- **Southwest corner of former Building 343 and east of former Building 475:** PCBs. Residual contamination in this area appears to be related to the transformer formerly located in Building 475 and the release of oils from sandblasting equipment.
- **Southeast corner of former Building 343 and northeast corner of former Building 344:** iron, lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to historical releases from former AST 344D, sandblasting of lead-based paints, and lubricants used for sheet metal fabrication. The floor of former Building 343 was rusted, which may have released metals to nearby soil.
- **Southwest corner of the site:** pesticides, PCBs, and VOCs. This area was used between 1995 and 1997 for temporary storage of PCB- and lead-contaminated soil excavated from IR Site 15 (see Section 1.3.3.1). Residual contamination in this area may be related to operation of the TSTA and application of pesticides for weed control.

## 4.2

## NATURE AND EXTENT OF GROUNDWATER CONTAMINATION

During the environmental investigations described in Section 1.3.4, 44 groundwater samples were collected at IR Site 34 and analyzed for the analytical groups listed in Table 1-2. Groundwater sampling locations are shown on Figure 1-5. Table 4-3 provides a statistical summary of analytical results for groundwater samples at IR Site 34. The table lists all chemicals that were detected in groundwater samples from IR Site 34, and identifies those chemicals that exceeded comparison criteria. For the nature and extent discussion, analytical results were compared to tap water PRGs and Water Board ESLs. Potential risk from groundwater by the vapor intrusion pathway is evaluated in the HHRA, which is summarized in Section 6.0 and presented in Appendix H. Potential risk from groundwater to aquatic receptors is evaluated in the SLERA qualitative evaluation through a comparison with aquatic comparison criteria, which is summarized in Section 7.0 and presented in Appendix I.

### 4.2.1 Metals in Groundwater

Analysis of 30 groundwater samples shows that 15 metals detected at IR Site 34 exceeded background concentrations; however, only three metals (arsenic, iron, and manganese) were present at concentrations exceeding EPA tap water PRGs and background concentrations in groundwater at the site (see Table 4-3). Nineteen grab groundwater samples were collected from 19 temporary monitoring well locations and analyzed for dissolved metals, and 11 groundwater samples were collected from a temporary monitoring well location and 5 permanent monitoring well locations and analyzed for total metals. Table 4-3 also shows that seven metals (aluminum, antimony, beryllium, chromium, mercury, silver, and zinc) were not detected above PRGs or background concentrations; selenium and thallium have no background concentrations. Further evaluation indicated that the distribution of six metals (barium, cobalt, iron, manganese, molybdenum, and selenium) was different at IR Site 34 from the background area, as shown in Table 4-4 and Appendix G. Statistical analysis determined that the remaining 13 detected metals were not distributed differently at IR Site 34 than in the background area (see Table 4-4). Concentrations of arsenic, iron, and manganese exceeded comparison criteria. Chromium had a detection frequency greater than 50 percent across the site, but it did not exceed the background concentration for Alameda Point, as discussed below.

Arsenic was detected in groundwater samples at concentrations exceeding the EPA tap water PRG (0.04 micrograms per liter [ $\mu\text{g/L}$ ]) in 19 of 19 samples analyzed for dissolved metals and in 10 of 11 samples analyzed for total metals. The concentrations of arsenic in samples analyzed for dissolved metals ranged from 2.5 to 110  $\mu\text{g/L}$ , and samples analyzed for total metals ranged from 3.4 to 15  $\mu\text{g/L}$  (see Table 4-3). Of the dissolved metals samples with exceedances of the PRG, only nine of the samples exhibited concentrations exceeding the background concentration of 7.2  $\mu\text{g/L}$ . (see Figure 4-15). In samples analyzed for dissolved metals, the two highest exceedances (110 and 15  $\mu\text{g/L}$ ) were in samples collected from temporary well locations DP15 and DP06, respectively. DP15 is located along the southern perimeter of Building 331 near the former AST and railroad track, and DP06 is located in the northwest corner of IR Site 34 along the fence line. In samples analyzed for total metals, the two highest exceedances (15 and 13  $\mu\text{g/L}$ ) were in samples collected from permanent monitoring wells MW-23 and MW-22,

respectively. Monitoring well MW-23 is located along the fence line west of IR Site 34 and monitoring well MW-22 is located in the southwestern quadrant of IR Site 34 near the former fuel pipeline. Sampling locations where concentrations of arsenic in groundwater exceeded comparison criteria are shown on Figure 4-15.

Iron was detected in groundwater samples at concentrations exceeding the EPA tap water PRG (10,900 µg/L) in 2 of 19 samples analyzed for dissolved metals. Iron was not detected above the comparison criteria in samples analyzed for total metals. The background concentration for iron in dissolved samples is 2,260 µg/L (see Table 4-3). The concentrations of iron in samples analyzed for dissolved metals ranged from 54 to 22,000 µg/L. The two exceedances (11,000 and 22,000 µg/L) were collected from temporary monitoring well locations DP05 and DP06, respectively. DP05 is located in the central portion of IR Site 34, and DP06 is located along the fence line in the northwestern quadrant of IR Site 34 (see Figure 1-5). The average detected concentrations (3,180 and 1,200 µg/L) of iron across IR Site 34 for samples analyzed for dissolved and total metals, respectively, are below the comparison criterion (see Table 4-3).

Manganese was detected in groundwater samples at concentrations exceeding the EPA tap water PRG (876 µg/L) in 4 of 19 samples analyzed for dissolved metals and in 4 of 11 samples analyzed for total metals. The concentrations of manganese in samples analyzed for dissolved metals ranged from 30 to 26,000 µg/L, and samples analyzed for total metals ranged from 48 to 3,000 µg/L (see Table 4-3). The background concentration for manganese in dissolved samples is 542 µg/L. The three highest exceedances (1,600, 26,000, and 26,000 µg/L) in samples analyzed for dissolved metals were collected from temporary well locations DP16, DP17, and DP18, respectively. DP16 and DP17 are located along the fence line in the northeastern quadrant of IR Site 34 and north of the former Building 331, and DP18 is located near GAP 78. In samples analyzed for total metals, the two highest exceedances (2,000 and 3,000 µg/L) were collected from permanent monitoring wells MW-23 and MW-24, respectively. Monitoring well MW-23 is along the fence line west of IR Site 34, and monitoring well 34 MW24 is located in the northwest corner of IR Site 34. Sampling locations where concentrations of manganese in groundwater exceeded comparison criteria are shown on Figure 4-16.

Chromium (total) was detected in 17 of 19 samples analyzed for dissolved metals and 2 of 11 samples analyzed for total metals. The concentrations of chromium in samples analyzed for dissolved metals ranged from 0.58 to 2.9 µg/L, and samples analyzed for total metals ranged from 4.5 to 8.5 µg/L (see Table 4-3). The comparison criteria used at IR Site 34 do not include a value for chromium; therefore, detected concentrations of chromium were not compared with a criterion. Chromium was detected in almost all groundwater samples collected for dissolved metals analysis. Detected concentrations of chromium in dissolved metal samples were below the background concentration of 3.19 µg/L. The three highest chromium concentrations (2.9, 2.4, and 2.1 µg/L) in samples analyzed for dissolved metals were collected from temporary well locations DP05, DP09, and DP11, respectively. DP05 is located in the central portion of IR Site 34, DP09 is located between former Buildings 344 and 474, and DP11 is located along the fence line in the northern portion of IR Site 34 (see Figure 1-5). The highest chromium concentrations (8.5 and 4.5 µg/L) detected in samples analyzed for total metals were collected from permanent monitoring wells MW-21 and MW-24, respectively. Monitoring well MW-21 is located in the

central portion of IR Site 34 and monitoring well 34 MW24 is located in the northwest corner of IR Site 34 (see Figure 1-5).

Although metals are present in groundwater across IR Site 34, only arsenic, manganese, and iron were reported at concentrations exceeding comparison criteria. Chromium, although it does not have a specific comparison criterion, had a high detection frequency across IR Site 34 in groundwater samples analyzed for dissolved metals.

#### 4.2.2 Volatile Organic Compounds in Groundwater

Groundwater samples from IR Site 34 were analyzed for VOCs by three analytical methods, as summarized in Table 4-3. Twenty eight samples were analyzed for VOCs by US EPA Method 8260B and 2 sample were analyzed US EPA Method 8020A. Analysis of groundwater samples collected from IR Site 34 shows that 29 VOCs were detected (see Table 4-3). Twenty grab groundwater samples were collected from 20 temporary monitoring wells, and 10 groundwater samples were collected from 5 permanent monitoring wells. Thirteen of the 29 detected VOCs were present only at one well location. Eight VOCs (1,1-dichloroethane [-DCA], 1,2-DCB, 1,2-DCA, bromoform, naphthalene, n-propylbenzene, sec-butylbenzene, and trans-1,2-dichloroethene [-DCE]) were detected at two well locations. m,p-Xylene and 2-hexanaone were detected in three samples collected from temporary monitoring well locations, and benzene was detected in five samples collected from temporary monitoring well locations. Six (1,2-DCA, 1,2-dichloropropane, chloroform, naphthalene, trichloroethene [TCE], and vinyl chloride) of the 28 VOCs were reported at or above EPA tap water PRGs and three (cis-1,2,-DCE, carbon disulfide, and toluene) had a 50 percent or greater detection frequency, as discussed below.

1,2,-DCA was detected in 2 of 30 samples at concentrations of 0.3 and 1.7 µg/L in samples collected at temporary monitoring well locations DP05 and DP16, respectively. These detected concentrations exceeded the EPA tap water PRG (0.12 µg/L). DP05 is located in the center of IR Site 34 and DP16 is located north of Building 331 (see Figure 1-5).

1,2-Dichloropropane was detected in 1 of 30 samples at an estimated concentration of 0.2 µg/L collected from temporary well location DP16, north of former Building 331 (see Figure 1-5). This estimated concentration is equal to the EPA tap water PRG (0.2 µg/L) (see Table 4-3).

Chloroform was detected in 1 of 30 samples at a concentration of 1.6 µg/L collected from temporary well location DP12, northeast of the former Building 330 (see Figure 1-5). This concentration exceeded the EPA tap water PRG (0.2 µg/L) (see Table 4-3).

Naphthalene was detected in 2 of 30 samples at concentrations 0.09 and 1.0 µg/L in samples collected from MW-23 and temporary well location DP16, respectively. These concentrations equal or exceeded the US tap water PRG (0.09 µg/L) (see Table 4-3). Monitoring well MW-23 is located off site to the west of the site and DP16 is located north of former Building 331 (see Figure 1-5).

TCE was detected in 8 of 30 samples at concentrations ranging from 0.2 to 0.6 µg/L. Concentrations of TCE exceeded the EPA tap water PRG (0.03 µg/L) in 5 grab groundwater samples collected from temporary monitoring wells and 3 groundwater samples collected from permanent monitoring wells. These exceedances were detected in samples from the southwest portion of IR Site 34 and off site to the west of the site (DP01, DP03, DP19, MW-20, MW-21, and MW-22) and near Building 474 (DP09) and GAP 78 (DP18). The highest detection of TCE (0.6 µg/L) was reported at two temporary monitoring well locations (DP03 and DP19). Based on detected concentrations, a TCE groundwater plume has been defined in the southwestern portion of IR Site 34 and the central portion of the site (see Figure 4-17).

Vinyl chloride was detected in 1 of 30 samples at a concentration of 0.2 µg/L collected from temporary well location DP19, off site to the west of the site (see Figure 1-5). This concentration exceeded the EPA tap water PRG (0.02 µg/L) (see Table 4-3).

cis-1,2-DCE was detected in 14 of 30 samples (10 grab groundwater samples collected from temporary monitoring wells and 4 groundwater samples collected from permanent monitoring wells). Concentrations of cis-1,2-DCE ranged from 0.1 to 1.7 µg/L, and do not exceed the comparison criteria. Cis-1,2-DCE is a degradation product of TCE, which was detected across IR Site 34 (see Figure 4-18). Based on detected concentrations and the location of the TCE groundwater plume, a cis-1,2-DCE plume can be defined across most of IR Site 34 (see Figure 4-18).

Carbon disulfide was detected in 21 of 30 samples (18 grab groundwater samples collected from temporary monitoring wells and 3 groundwater samples collected from permanent monitoring wells). Concentrations of carbon disulfide ranged from 0.08 to 1.1 µg/L, and do not exceed comparison criteria.

Toluene was detected in 16 of 30 samples; all 16 grab groundwater samples were collected from temporary monitoring wells. Concentrations of toluene ranged from 0.07 to 0.6 µg/L, and do not exceed comparison criteria.

Two groundwater plumes, TCE and cis-1,2-DCE, were identified at IR Site 34. The TCE groundwater plume is smaller and is located in the southeastern and central portion of the site (see Figure 4-17). The cis-1,2-DCE groundwater plume is larger than the TCE groundwater plume and covers most of IR Site 34 (see Figure 4-18). The lateral extent of VOC contamination at IR Site 34 appears to have been sufficiently characterized.

#### **4.2.3 Semivolatile Organic Compounds in Groundwater**

Analysis of 35 groundwater samples shows three SVOCs were detected in groundwater samples from IR Site 34 (see Table 4-3). A total of 25 grab groundwater samples were collected from 25 temporary monitoring well locations and 10 groundwater samples were collected from 5 permanent monitoring well locations. The three detections were in grab groundwater samples

collected at the five temporary monitoring well locations. SVOCs were not detected in groundwater samples collected from the five permanent groundwater monitoring well locations.

Acenaphthene was detected in samples from two locations, DP16 and DP19; bis(2-ethylhexyl)phthalate was detected in one sample from location 018-007-036; and phenol was detected in samples from three locations, DP05, DP15, and DP17. These detected SVOCs were all less than the comparison criteria.

#### 4.2.4 Polycyclic Aromatic Hydrocarbons in Groundwater

Analysis of 28 groundwater samples shows that 17 PAHs were detected in groundwater samples (see Table 4-3). Eighteen grab groundwater samples were collected from 18 temporary monitoring well locations, and 10 groundwater samples were collected from 5 permanent monitoring well locations. Three of the 17 detected PAHs were reported at concentrations exceeding EPA tap water PRGs, as discussed below.

B(a)P was detected in 1 of 28 samples at a concentration of 0.08 µg/L collected from temporary well location DP05 in the central portion of IR Site 34 (see Figure 1-5). This concentration of B(a)P exceeded the EPA tap water PRG (0.01 µg/L).

Dibenzo(a,h)anthracene was detected in 1 of 28 samples at a concentration of 0.014 µg/L collected from temporary well location DP05 in the central portion of IR Site 34 (see Figure 1-5). This concentration of dibenzo(a,h)anthracene exceeded the EPA tap water PRG (0.01 µg/L).

Naphthalene was detected in 6 of 28 samples, 4 grab groundwater samples from temporary monitoring well locations and 2 groundwater samples from permanent monitoring wells. The concentrations of naphthalene ranged from 0.02 to 0.2 µg/L. Two of the concentrations exceeded the EPA tap water PRGs (0.09 µg/L); one sample was collected from temporary monitoring well location DP01, and one sample was collected from permanent monitoring well location MW-21.

All of the samples with PAH concentrations exceeding PRGs were confined to three locations in the southwestern to central portion of IR Site 34. The groundwater sample collected at location MW-21 near the central portion of the site exhibited the highest concentration of all 17 PAHs detected in groundwater. Analysis of groundwater samples surrounding the three locations where PAHs were detected showed a limited lateral extent of PAHs in groundwater. The lateral extent of PAH contamination in groundwater appears to be sufficiently characterized.

#### 4.2.5 Pesticides in Groundwater

Analysis of 29 groundwater samples shows that 15 pesticides were detected in groundwater (see Table 4-3). At one sample location, pesticide data was rejected because of laboratory quality control (see Appendix F for a detailed discussion of this rejection). As a result of the data

rejection, some of the pesticides associated with this sample have 28 groundwater samples being analyzed for pesticides (see Table 4-3). Nineteen grab groundwater samples were collected from 19 temporary monitoring well locations, and 10 groundwater samples were collected from 5 permanent monitoring wells. The following pesticides were detected in samples collected from temporary and permanent monitoring well locations:

- Beta-benzene hexachloride (-BHC), dieldrin, endosulfan II, and gamma-chlordane (one location)
- 4,4-Dichlorodiphenyldichloroethane (DDD), endrin, heptachlor epoxide, and methoxychlor (two locations)
- 4,4-Dichlorodiphenyldichloroethene (DDE) (three locations)
- Endrin aldehyde and alpha-BHC (four locations)
- Alpha-chlordane and gamma-BHC (lindane) (five locations)
- Aldrin (eight locations)
- Endosulfan I (nine locations)

Detected concentrations of the pesticides did not exceed comparison criteria. The comparison criteria used at IR Site 34 did not have a value for endosulfan I. Endosulfan I was detected in 9 of 29 samples at concentrations ranging from 0.00012 to 0.002 µg/L.

#### **4.2.6 Polychlorinated Biphenyls in Groundwater**

PCBs were not detected in groundwater at IR Site 34 (see Table 4-3).

#### **4.2.7 Total Petroleum Hydrocarbons in Groundwater**

Thirty five groundwater samples at IR Site 34 were analyzed for gasoline-range petroleum hydrocarbons and 37 groundwater samples were analyzed for diesel- and motor oil-range petroleum hydrocarbons. Analysis of the groundwater samples shows that diesel-, gasoline-, and motor oil-range petroleum hydrocarbons were detected in groundwater (see Table 4-3). Diesel- and motor oil-range petroleum hydrocarbons had a greater than 50 percent detection frequency across IR Site 34 (see Figures 4-19 and 4-20).

TPH as diesel was detected in 26 of 37 groundwater samples from 26 well locations (22 temporary wells and 4 permanent monitoring wells). Detected concentrations ranged from 0.087 to 54 mg/L. The three highest TPH as diesel concentrations (54, 1.4, and 1.3 mg/L) were detected in samples collected from temporary monitoring well locations DP12, DP15, and 004-003-009, respectively. DP12 is located northeast of the former Building 330, downgradient from a former AST; DP15 is located along the southern perimeter of former Building 331 near a

former AST; and 004-003-009 was collected along the southern perimeter of former Building 331 adjacent to a former AST (see Figure 4-19). The remaining detections from samples collected across IR Site 34 were at concentrations less than 1.0 mg/L (see Figure 4-19).

TPH as motor oil was detected in 25 of 37 samples, all collected from temporary monitoring well locations, at concentrations ranging from 0.037 to 7.1 mg/L. The three highest TPH as motor oil concentrations (7.1, 1.4, and 1.0 mg/L) were detected in samples collected from temporary monitoring well locations DP12, DP14, and DP07, respectively. DP12 is located northeast of the former Building 330 and downgradient from a former AST, DP14 is located along the southeastern boundary of IR Site 34 near a former UST located on the adjacent parcel, and DP07 was collected southeast of the former Building 472 near GAP 78 (see Figure 4-20). The remaining detections from samples collected across IR Site 34 were at concentrations less than 1.0 mg/L (see Figure 4-20).

TPH as gasoline was detected in 7 of 35 groundwater samples collected from four temporary monitoring wells and three permanent monitoring wells at concentrations ranging from 0.028 to 1.1 mg/L. TPH as gasoline was detected in two temporary monitoring well locations north of Building 331 (DP12 and DP16). The highest detected concentration TPH as gasoline was in a sample collected from DP12 (see Figure 4-21). TPH as gasoline also was detected in two samples collected near the former fuel pipeline (030-FLI-519 and 018-007-033), and in three of the permanent monitoring wells (MW-20, MW-23, and MW-24) (see Figure 4-21).

TPH as diesel and TPH as motor oil were detected in groundwater samples collected across IR Site 34. The highest detected concentrations of TPH as diesel and TPH as motor oil were in groundwater samples that were collected near or downgradient from former ASTs and USTs, or GAPs. TPH as gasoline was detected near or downgradient from former ASTs and fuel pipelines. TPH as diesel and TPH as gasoline were also detected in the permanent monitoring wells.

#### **4.2.8 Summary of Contamination in Groundwater**

Metals, VOCs, and PAHs were detected at concentrations exceeding comparison criteria in groundwater samples collected at IR Site 34. There are no groundwater comparison criteria for petroleum hydrocarbons; however, diesel- and motor oil-range petroleum hydrocarbons had a greater than 50 percent detection frequency across IR Site 34. The most likely sources of these chemicals are from the disposal of used sandblasting and paint grit; painting activities; chemical storage; sheet metal fabrication; spills near the GAP; leaks from ASTs; and application of chemicals for weed control. Historical site activities are discussed in Section 1.3.3. However, all of these potential sources were removed after closure of NAS Alameda in 1997. Groundwater contamination at IR Site 34 appears to be confined to several specific areas. Many of the specific areas have multiple chemicals at concentrations above PRGs. EPA tap water PRGs are an overly conservative comparison criterion for groundwater at IR Site 34 given groundwater beneath the site is not considered a drinking water source, the intended future site use as a golf course, and the restriction of residential use of tidelands trust areas. The list below

indicates which chemicals were detected above the EPA tap water PRGs at each of the contamination areas and identifies likely historical sources of the contaminants.

- In the area north of former Building 331: arsenic, manganese, 1,2-DCA, 1,2-dichloropropane, and naphthalene were detected at or above PRGs. TPH as diesel and TPH as motor oil were detected at this location. Chemicals in groundwater in this area appear to be related to historical releases from former AST 331 and use of oils and solvents for woodwork at the former building.
- Former Buildings 474, 476, 477, and 604 and GAP 78 near the central portion of the site: arsenic, chromium, manganese, and TCE were detected above PRGs. TPH as diesel and TPH as motor oil also were detected at this location. Contamination in groundwater in this area appears to be related to use of oils and solvents for sheet metal fabrication at former Building 474, paint storage and use at former Buildings 476 and 477, paint removal activities at former Building 604, and accumulation of waste paints and solvents at GAP 78.
- Near the former fuel pipeline in the southwest portion of IR Site 34: arsenic and PAHs were detected above PRGs. TPH as diesel and TPH as motor oil also were detected at this location. Chemicals in groundwater in this area appear to be related to historical releases of petroleum from the former fuel pipeline.
- The open area in the western-central portion of the site: arsenic, iron, PAHs, and TCE were detected above PRGs. This area is downgradient from the former fuel pipeline. Chemicals in groundwater in this area appear to be related to historical releases of petroleum from the former fuel pipeline. Historical sources for TCE at this location are not apparent.
- Samples from former ASTs 330B, 331, 344A, 344B, and 344D: TPH as diesel and TPH as motor oil were detected.

### 4.3 NATURE AND EXTENT CONCLUSIONS

Sections 4.1 and 4.2 discussed the analytical results of soil and groundwater samples, respectively. The soil comparison criteria include EPA and California-modified residential and industrial PRGs, Water Board ESLs (for diesel, gasoline, and motor oil), background concentrations of metals (Pink Fill Area), screening level established by the Navy and agencies for PAHs as average B(a)P equivalent concentrations. The groundwater comparison criteria include EPA tap water PRGs and Water Board ESLs for evaluation of potential vapor intrusion concerns for residential land use in high-permeability vadose zone soils. Using residential PRGs and EPA tap water PRGs to evaluate the nature and extent of contamination at IR Site 34 may be an overly conservative comparison given the intended future use as a golf course and the restriction against residential use of tidelands trust areas.

The following chemicals exceeded comparison criteria for soil at IR Site 34:

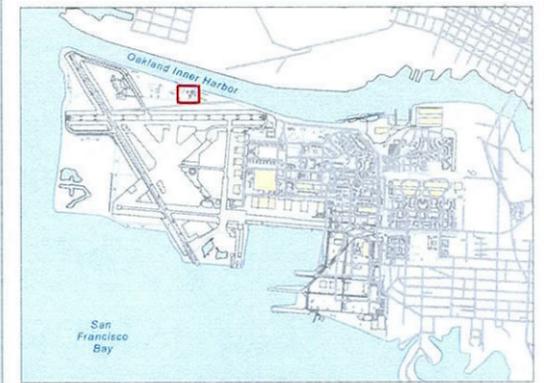

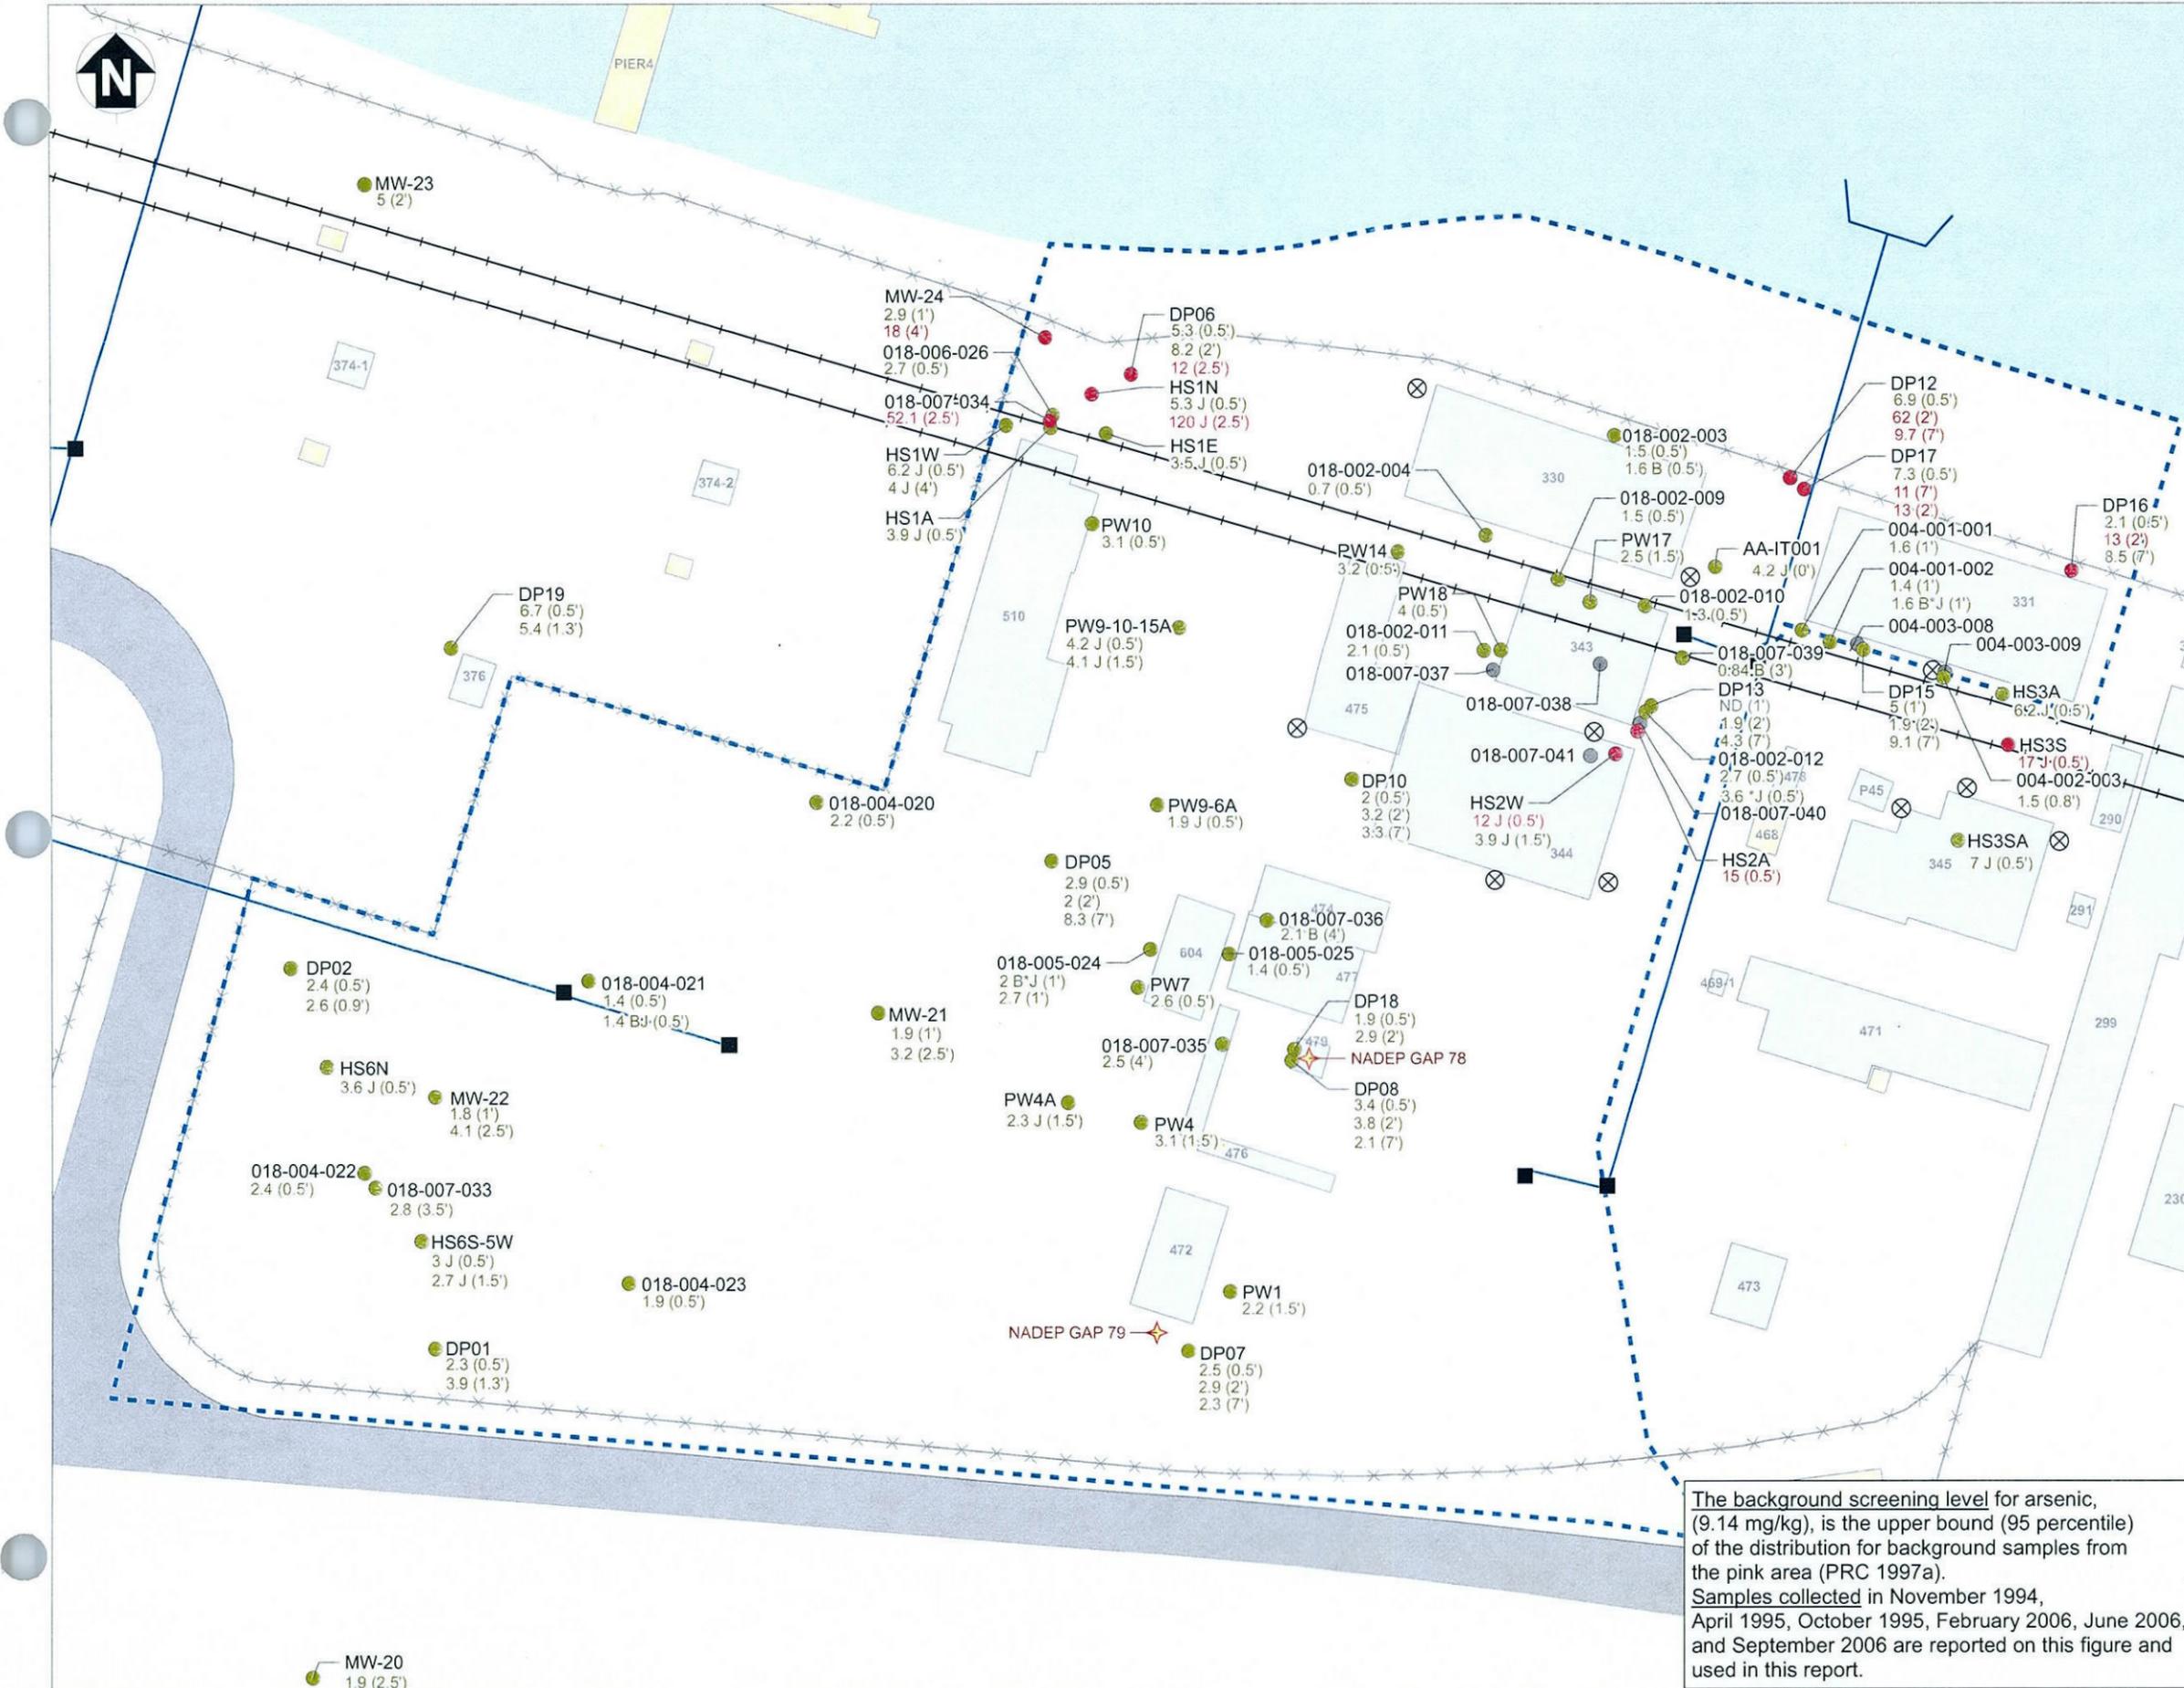

- Arsenic, cadmium, chromium, iron, lead, and vanadium
- 1,4-DCB
- Dieldrin and heptachlor epoxide
- Aroclor-1248, Aroclor-1254, Aroclor-1260, and Aroclor-1268
- TPH as diesel and motor oil

The following chemicals exceeded comparison criteria for groundwater at IR Site 34:

- Arsenic, manganese, and iron
- 1,2-DCA, 1,2-dichloropropane, chloroform, TCE, and vinyl chloride
- PAHs: B(a)P, dibenzo(a,h)anthracene, and naphthalene

The background screening level for chromium, (54.8 mg/kg), is the upper bound (95 percentile) of the distribution for background samples from the pink area (PRC 1997a). X-Ray fluorescence (XRF) was used for field screening purposes, numerical results are not shown on the figure. Twenty percent of XRF samples were also submitted to a fixed lab for analysis. XRF results for chromium appear to have a high bias relative to fixed lab results, but a statistical comparison was not performed. Samples collected in November 1994, April 1995, October 1995, February 2006, June 2006, and September 2006 are reported on this figure and used in this report. Hexavalent chromium was not detected in any of the 24 samples submitted for hexavalent chromium analysis.

The background screening level for cadmium, (1.72 mg/kg), is the upper bound (95 percentile) of the distribution for background samples from the pink area (PRC 1997a).  
 Samples collected in November 1994, April 1995, October 1995, February 2006, June 2006, and September 2006 are reported on this figure and used in this report.

**TABLE 4-1: SUMMARY OF ANALYTICAL RESULTS FOR CHEMICALS DETECTED IN SOIL SAMPLES (CONTINUED)**

Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Chemical	Number of Detections/Analyses	Range of Detected Concentrations	Range of Nondetected Concentrations	Number of Detected Concentrations Above Comparison Criteria; Above Background	Values for Comparison Criteria; Background Concentration	Average of Detected Concentrations; 95UCL of Detected Concentrations
----------	-------------------------------	----------------------------------	-------------------------------------	---	--	--

Notes:	Comparison criteria are EPA Region 9 residential PRGs unless otherwise noted
	Background concentrations are the upper bound (95 percentile) of the distribution in the pink fill area.
	All concentrations are reported in milligrams per kilogram.
a	Statistics calculated with two high outlier concentrations (180,000 mg/kg and 120,000 mg/kg) removed
b	California-modified residential PRG
c	Analyzed by EPA CLP methods, EPA Method 8260, or EPA Method AROMV
d	Analyzed by EPA CLP methods or EPA Method 8270c
e	Analyzed by EPA Method 8270c-SIM
f	Statistics calculated with one outlier concentration (8.41 mg/kg) removed
g	PRG for technical chlordane
h	PRG for endosulfan
i	PRG for endrin
j	PRG for unspecified mixture, high risk
k	San Francisco Bay Regional Water Quality Control Board environmental screening level for shallow soil that is not a source for drinking water
*	Duplicate analysis not within control limits
95UCL	95 percent upper confidence limit of the mean. Concentrations do not include X-ray fluorescence field screening data. Calculation is similar but not equal to that used in the
B	Reported value less than the contract-required detection limit, but greater than the instrument detection limit.
B(a)P equivalent	Benzo(a)pyrene-equivalent concentration. Comparison criteria are screening criteria established by the Navy and regulatory agencies (see text in Section 3.3).
BHC	Benzene hexachloride
CLP	Contract Laboratory Program
DDD	Dichlorodiphenyldichloroethane
DDE	Dichlorodiphenyldichloroethylene
DDT	Dichlorodiphenyltrichloroethane
E	Estimated because of interference
EPA	U.S. Environmental Protection Agency
J	Estimated concentration
mg/kg	Milligram per kilogram
NA	Not available (background concentrations available for metals only)
NC	Not calculated (not statistically meaningful)
P	This flag is used for gas chromatograph analysis when there is greater than 25 percent difference for detected concentrations between the two columns. The lower of the two values is reported and flagged with a "P."
PRG	Preliminary remediation goal
Z	Pattern does not resemble total petroleum hydrocarbon pattern

Vanadium	105	105	100	55	55	100	WRS	<0.001	N/A	YES
Zinc	101	105	96	54	55	98	WRS(G)	<0.001	N/A	YES

Notes:

- a TP= test of proportions (implemented using the Fisher exact test)  
 WRS= Wilcoxon rank sum test  
 WRS(G)= Gehan-Wilcoxon test  
 H<sub>0</sub> is that site ≤ background. Note that for TP, the test is comparing the frequency of detected measurements that exceed the maximum censored datum in the background data set.
- b Calculated significance level for individual statistical tests. Reject H<sub>0</sub> if Prob ≤ 0.05.
- c Conducted in cases where the WRS or WRS(G) test cannot be performed, or when H<sub>0</sub> is not rejected by these tests
- > Greater than H<sub>0</sub> Null hypothesis
- < Less than N/A Not applicable, H<sub>0</sub> was rejected based on either the WRS or WRS(G) test, or no test was performed.
- ≤ Less than or equal to NT Not tested, metal was not detected in the background data set. Conclusion is listed as EQUIVOCAL.

Zinc	23	29	79	0	65	198	33	0	TP	0.373	Site ≤ Background	NO

Notes:

- a Sample size includes high censored results
- b Number of censored results that exceed the maximum detected concentration. These results were excluded from the statistical comparison tests.
- c TP= test of proportions (implemented using the Fisher exact test)  
WRS(G)= Gehan-Wilcoxon test  
H<sub>0</sub> is that site ≤ background. Note that for TP, the test is comparing the frequency of detected measurements that exceed the maximum censored datum in the background data set.
- d Calculated significance level for individual statistical tests. Reject H<sub>0</sub> if Prob ≤ 0.05.
- e Conducted in cases where the WRS(G) test cannot be performed, or when H<sub>0</sub> is not rejected by this test
- > Greater than H<sub>0</sub> Null hypothesis
- < Less than N/A Not applicable, H<sub>0</sub> was rejected by the WRS(G) test, or no test was performed.
- ≤ Less than or equal to
- (1) Quantile test could not be conducted because one or more censored results was present in the right-hand tail of the combined site and background data set
- (2) Conclusions from the statistical tests are considered equivocal when the result for the test of proportions is nonsignificant and the quantile test cannot be conducted because of (1). In these cases, conclusions are based on qualitative evaluation of outlier box-plots and quantile probability plots, with an emphasis on comparing the range of detected results.
- (3) Conclusion is based on comparison of the detection frequencies and the maximum detected results in the site and background data sets

## 5.0 FATE AND TRANSPORT OF CHEMICALS IN SOIL AND GROUNDWATER AT IR SITE 34

This section describes the fate and transport mechanisms for the chemicals of interest (COI) in soil and groundwater at IR Site 34. Fate and transport modeling for chemicals in groundwater was not conducted; therefore, the discussion of chemical fate and transport is based on qualitative assessments. Fate and transport of chemicals in environmental media is controlled by the physical properties of the media in which the chemicals reside, such as lithologic characteristics and geochemical conditions, and physical properties of the chemicals, such as affinity for organic carbon, and tendency to volatilize. This evaluation assesses whether the chemicals identified in the nature and extent evaluation as exceeding comparison criteria have migrated or degraded, are being released from a continuing source of contamination, or are likely to be distributed by groundwater or other potential pathways.

This section includes (1) a summary of COIs at the site (this section), (2) a discussion of the primary transport processes that may mobilize these chemicals in soil and groundwater (see Section 5.1); (3) identification of the physical characteristics and primary fate processes that affect the COIs (see Section 5.2); (3) development of a conceptual model of fate and transport processes that are expected to affect the COIs at IR Site 34 (see Section 5.3); and (4) a qualitative summary of the fate and transport of the COIs (see Section 5.4).

The discussion is focused on chemicals reported in soil and groundwater samples at concentrations exceeding comparison criteria, as presented in Sections 4.1 and 4.2. Based on the analysis presented in these sections, a number of contaminants are present at IR Site 34 at levels of potential concern. These include:

The following COIs were identified for soil (see Section 4.1):

- Six metals (arsenic, cadmium, chromium, iron, lead, and vanadium)
- One VOC (1,4-DCB)
- PAHs
- Two pesticides (dieldrin and heptachlor epoxide)
- Four PCBs (Aroclors-1248, -1254, -1260, and -1268)
- Petroleum hydrocarbons (including diesel-range and motor oil-range hydrocarbons)

The following COIs were identified for groundwater (see Section 4.2):

- Three metals (arsenic, iron, and manganese)
- Five VOCs (1,2-DCA, 1,2-chloropropane, chloroform, TCE, and vinyl chloride)

- Three PAHs [B(a)P, dibenzo(a,h)anthracene, and naphthalene]
- Petroleum hydrocarbons (including diesel-range and motor oil-range hydrocarbons)

## **5.1 POTENTIAL MIGRATION PATHWAYS**

Chemicals may migrate from affected areas at IR Site 34 through several potential routes or pathways. These potential migration pathways are summarized below.

- Chemicals in soil can migrate from unpaved surfaces to different locations by particulate dispersion via airborne dust and surface water runoff.
- VOCs in soil and groundwater can volatilize into air.
- Chemicals in soil can migrate to groundwater by infiltration of surface water and by groundwater table fluctuations caused by storm events, seasonal variations, and tidal influence.
- Chemicals in groundwater can migrate to the Oakland Inner Harbor or to deeper aquifers by groundwater flow.
- Chemicals in groundwater can migrate through preferential flow pathways such as stormwater drains to the Oakland Inner Harbor.

The following subsections discuss the significance of the transport mechanisms that drive each of these potential migration pathways at IR Site 34.

### **5.1.1 Particulate Dispersion**

Particulate dispersion is the process by which solids (either adsorbed to soil particles or as residual product) are transported as airborne or waterborne particulates by mechanical processes or through human or biological agents. The amount of contaminated material transported by wind or water or biological agents depends on the extent and magnitude of contamination, and proximity of chemicals to the surface. Because the surface cover at IR Site 34 is minimal, soil erosion (as wind drift, sediment transport and surface runoff) is a likely current transport mechanism. However, the planned reuse of the site as a golf course is expected to reduce the significance of this dispersal mechanism.

### **5.1.2 Volatilization to Ambient Air**

Volatilization is the process by which liquids and solids vaporize and escape to the atmosphere. VOCs dissolved in groundwater or present in soil can volatilize and migrate into the vadose zone (soil gas) and into the atmosphere. Results of the RI sampling activities confirmed minimal concentrations of VOCs in the soil vadose zone and in groundwater. Because concentrations of

VOCs in soil and groundwater at IR Site 34 are relatively low, volatilization from soil and groundwater is considered a minor transport pathway.

### **5.1.3 Infiltrating Precipitation or Fluctuating Groundwater Table**

Another possible transport pathway at IR Site 34 is leaching from vadose zone soil into groundwater caused by infiltration of rainwater. Transport from soil to groundwater can also occur when fluctuations of the groundwater table result in groundwater coming in contact with contaminated soil, allowing chemicals to dissolve into groundwater. Tidally induced fluctuations of the water table are known to occur at IR Site 34, and may extend inland as far as 300 feet from the shoreline of the Inner Harbor.

The potential for chemicals to leach from soil to groundwater depends on the concentration and solubility of the chemicals present in soil, the soil texture, the net volume and rate of precipitation infiltration, and the frequency and duration of tidal inundation and seasonal variations. Because most of IR Site 34 is unpaved, the migration of chemicals caused by infiltrating precipitation is considered a likely transport pathway. However, most of the chemicals identified in soil at Site 34 were detected infrequently, at relatively low concentrations, and generally have low solubilities. Therefore, the leaching potential for these chemicals is low as further confirmed by the lack of their detections in groundwater. Leaching of residual chemicals from soil to groundwater as a result of fluctuation of groundwater elevations is also considered a likely transport mechanism at IR Site 34. Both seasonal and tidal fluctuations of groundwater elevation may transport chemicals from the soil to the groundwater, and tidal fluctuations have been observed at nearby IR sites with similar lithology. However, the nature and extent of soil contamination discussed in Section 4.1 indicates that most of the soil contamination present at IR Site 34 is in shallow soils outside the range of tidal fluctuations of groundwater elevation; therefore, reducing the significance of seasonal and tidal groundwater elevation fluctuations as a chemical transport mechanism.

### **5.1.4 Groundwater Migration**

Vertical or horizontal migration of chemicals dissolved in groundwater is controlled by flow velocity, dispersion, diffusion, retardation, and natural attenuation mechanisms. Groundwater of the FWBZ is present at IR Site 34 under unconfined conditions at depths ranging from approximately 2.4 to 4 feet bgs. Vertical migration of groundwater to deeper aquifers is not considered a significant transport pathway at IR Site 34 because a thick clay aquitard layer underlies the surficial fill layer at the site. Lithologic information from the deep borings at the site (wells MW7C and MW-24, 60 feet deep) indicates that up to a 15-foot-thick clay layer separates the shallow and deep aquifers at IR Site 34. At the locations of deep borings DP17 and DP-18 (see Appendix B), the aquitard layer was not encountered at 44 feet bgs (geoprobe refusal), but is likely present deeper as indicated by the boring logs for wells MW7C and MW-24. However, horizontal migration of chemicals with groundwater (with some vertical flow component due to tides) is considered a likely transport pathway for the site.

## 5.1.5 Subsurface Conduits

Pipes and pipe bedding can act as conduits that aid migration of dissolved chemicals through the subsurface. Within the saturated zone, areas with greater hydraulic conductivity will allow more rapid groundwater flow, thus they may represent a preferential pathway.

Potential preferential flow pathways at IR Site 34 include a storm sewer line west of former Buildings 331, 345, and 471 and associated outfall, a storm sewer catch basin, and a portion of a storm sewer line in the undeveloped western portion of the site that continues and outfalls beyond IR Site 34. Migration of chemicals due to groundwater flow through subsurface conduits is considered a possible transport pathway for the site. Groundwater samples were collected from DP12 and DP17 (see Figure 1-5) to evaluate the potential for the storm sewer line to act as a preferential flow pathway. Detected chemicals were either below EPA tap water PRGs or below Alameda Point background concentrations for metals. Based on the data collected from these two points and the chemical distribution at the site, it does not appear that chemicals are migrating along this pathway.

## 5.2 PHYSICAL CHARACTERISTICS AND PRIMARY FATE PROCESSES THAT AFFECT CHEMICALS OF INTEREST

Chemical fate is the tendency of a chemical to undergo transformation or degradation. Mobility is the tendency of a chemical to move along a pathway in response to a driving force. The tendency toward immobility and persistence is a function of site-specific characteristics and the physical and chemical properties of the chemicals. These properties include aqueous solubility, tendency to transform or degrade (usually described as half-life or an environmental half-life in a given medium), and chemical affinity for adsorption to solids or organic matter (usually described by a partitioning coefficient). The following chemical classes are of interest at IR Site 34 because these chemical classes were detected in soils and groundwater at IR Site 34 at concentrations above residential soil PRGs (EPA 2004e), tap water PRGs (EPA 2004e), or Water Board ESLs (Water Board 2005):

- Metals in soils and groundwater
- VOCs in soil and groundwater
- PAHs in soil and groundwater
- Pesticides in soil
- PCBs in soil
- Petroleum hydrocarbons in soils and groundwater

The persistence and mobility of organic chemicals is governed by their physicochemical properties and by transformation mechanisms that act on them. The following subsections

present the specific physicochemical properties for the COIs. As described below, the compounds in each chemical group have similar physicochemical properties that influence their mobility or persistence in the environment.

## **5.2.1 Metals**

Metals are not subject to many of the degradation reactions that affect organic chemicals because they are chemical elements rather than chemical compounds, making them naturally persistent in the environment. However, metals are strongly affected by chemical reduction and oxidation (redox) reactions that can change their ionic charge and species. Redox conditions strongly influence the transport behavior of each metal species in the environment because redox conditions control the ionic species of metals, and different ionic species have differing aqueous solubilities and determine whether the metal will be present as an immobile phase in soil or as a mobile phase dissolved in groundwater.

Metals detected in soils and groundwater at IR Site 34 include arsenic, cadmium, chromium, iron, lead, manganese, and vanadium. 95UCL concentrations of cadmium, chromium, and vanadium did not exceed either the Alameda site background concentration or their respective comparison criterion, and these metals are not discussed further. Chemical properties of arsenic, iron, lead, and manganese are discussed below.

### **5.2.1.1 Arsenic**

Arsenic occurs naturally over a wide range of concentrations and is ubiquitous in soils and groundwater in California (Shacklette and Boerngen 1984). Arsenic concentrations at IR Site 34 exceed comparison criteria in both soils and groundwater. In addition to occurring naturally in soils and groundwater in California, arsenic in soil may be attributed to dissolution of arsenic in paint chips and dust, pesticide use, and wood treatment, which may have been present in a soluble form.

Redox conditions greatly affect the transport of arsenic, because redox conditions control the ionic species of metals and different ionic species of arsenic have differing aqueous solubilities. In oxidizing conditions, the relatively insoluble arsenate species of arsenic predominates and arsenic mobility is low. In reducing conditions, the more soluble arsenite species predominates and is more likely to dissolve into the groundwater and mobilize arsenic (Van Deuren others 2002).

In soils, redox conditions are strongly controlled by microbial activity. Reducing conditions are brought about by the absence of oxygen, which may be caused when oxygen is consumed by microbial activity. Microbial biodegradation of organic chemicals such as petroleum hydrocarbons can consume the available oxygen in soil and cause the oxidation state of arsenic to change from the relatively insoluble arsenate species to the more soluble arsenite species. As a result, arsenic is likely to be mobilized in areas where the biodegradation of petroleum hydrocarbons creates reducing conditions. Arsenite, the mobile ionic species of arsenic, may

revert to the more immobile arsenate species when more oxidizing conditions are encountered outside the immediate zone where petroleum hydrocarbons are actively biodegrading.

#### **5.2.1.2 Iron**

Iron is a major constituent of soils with iron contents ranging between 0.5 percent and 5 percent (Kraemer, Kretzchmar, and Reichard 2004). Insoluble iron minerals exist as oxides, hydroxides, and oxyhydroxides and are ubiquitous in many natural soil systems. Not only is iron common, but it is also reactive and readily reflects changes in surrounding redox potential and pH conditions.

Generally, iron is relatively immobile in the environment. Sorption behavior is primarily related to pH (within the typical range of 5.0 to 8.0), and each ion has its own optimum pH range for adsorption. In groundwater systems, iron typically occurs in one of two oxidation states: reduced soluble divalent ferrous iron ( $\text{Fe}^{+2}$ ) or oxidized insoluble trivalent ferric iron ( $\text{Fe}^{+3}$ ) (Vance 2002). However,  $\text{Fe}^{+3}$  will be in solution only under very low pH (less than 3.0), while  $\text{Fe}^{+2}$  would predominate in groundwater under reducing conditions and typical pH range (Dragun 1998).

The pH measured in soil at Site 34 is predominantly neutral to basic. The pH measured in groundwater samples from wells is neutral or slightly greater than 7.0. Taking into account the pH measured in groundwater at Site 34 and likely presence of reducing conditions resulting from the microbial degradation of organic chemicals such as petroleum hydrocarbons,  $\text{Fe}^{+2}$  is expected to be prevalent in groundwater at Site 34. However, once conditions in groundwater become more oxidizing,  $\text{Fe}^{+2}$  is expected to precipitate out of solution as less soluble oxides and hydroxides of  $\text{Fe}^{+3}$ .

#### **5.2.1.3 Lead**

Lead is a naturally occurring element in soils, typically ranging from 10 to 150 mg/kg (Pierzynski, Sims, and Vance 1994). Lead is also found in many products, including fuels, paints, and batteries.

Lead has a high sorption coefficient and typically is sorbed strongly to soils, particularly fine-grained material that contains clay. Lead sorption is pH-dependant; at very low or very high pHs, lead can desorb and become mobile in groundwater. However, in most environmental conditions, lead becomes strongly sorbed to soils, where it is immobilized.

Considering predominantly neutral to basic pH measured in soil and groundwater at Site 34, lead is not expected to be mobile in soil and groundwater at Site 34.

#### **5.2.1.4 Manganese**

Manganese is a common naturally occurring element found in soils that has been detected at concentrations exceeding comparison criteria in groundwater at IR Site 34. Manganese is essential to iron and steel production, and may be found in certain aluminum alloys (United States Geological Survey [USGS] 2004). Manganese in aerobic soils is not considered very mobile. Precipitation of manganese oxides, adsorption, and ion exchange will effectively bind manganese in soils.

The chemistry of manganese in the environment is complex; manganese has several possible oxidation states in a soil-water environment (McComish and Ong 1988). Like arsenic, manganese solubility is controlled by the redox potential and the pH of the soil. Low pH or reducing conditions favor the presence of the more soluble manganese ( $Mn^{2+}$ ) state. Thus manganese is likely to be mobilized in areas where the biodegradation of petroleum hydrocarbons creates reducing conditions.

#### **5.2.2 Volatile Organic Compounds**

VOCs were detected in both soils and groundwater at IR Site 34, including the chlorinated solvents 1,4-DCB in soil and 1,2-DCA, 1,2-dichloropropane, chloroform, TCE, and vinyl chloride in groundwater. 1,2-DCE was detected in groundwater across IR Site 34, however, all detections were below PRGs, 1,2-DCE is not a COI. TCE, 1,2-DCE, and vinyl chloride are closely related degradation products, and the presence of 1,2-DCE and vinyl chloride suggest that natural microbial degradation of TCE is occurring at IR Site 34.

The physicochemical parameters that govern fate and transport of VOCs released to the environment include aqueous solubility, vapor pressure, organic-carbon-normalized partition coefficient ( $K_{oc}$ ), and Henry's law constant (Montgomery and Welkom 1989).

As discussed above, Henry's law constant represents the tendency of a dissolved gas to transfer from a dissolved phase to the atmosphere; higher Henry's law constants signify a greater tendency for compounds to transfer from an aqueous phase to a gaseous phase (Montgomery and Welkom 1989). VOCs present at IR Site 34 have relatively high Henry's Law constants, indicating that they would have a tendency to volatilize from aqueous solutions exposed to the atmosphere.

Vapor pressure is a measure of the tendency of a substance to evaporate. Higher vapor pressure indicates greater tendency to volatilize. VOCs, including those detected at IR Site 34, are a group of compounds with high vapor pressure and a high tendency to volatilize if exposed to air. Thus, if spilled on the ground surface or present in soils near the ground surface, the bulk of VOCs are expected to volatilize to the atmosphere.

The aqueous solubility of a chemical is a critical chemical property because transport is often by water. Highly soluble substances can be readily leached from soil and are generally mobile in

groundwater. Compounds detected at IR Site 34 are all relatively soluble and thus are likely to be mobilized from soil to groundwater, for example by infiltration of rainwater or tidal inundation.

The  $K_{oc}$  is a parameter that reflects the propensity of a compound to adsorb to organic matter (Montgomery and Welkom 1989). Higher  $K_{oc}$  values indicate greater sorption potential and less mobility in the saturated zone. Most soils at IR Site 34 are fine-grained sands deposited in an estuarine environment, and are expected to contain naturally occurring organic carbon, which should offer ample opportunity for adsorption. All of the compounds detected at concentrations exceeding comparison criteria at IR Site 34 have relatively high  $K_{oc}$  values, indicating that most VOCs would be expected to be slowed as they travel as a dissolved phase through the shallow aquifer. Relative to other compounds detected at concentrations exceeding comparison criteria, vinyl chloride has a lower  $K_{oc}$  value and is expected to be the most mobile.

In summary, the VOCs present at concentrations exceeding comparison criteria at IR Site 34 have properties that affect their fate and transport. Most of the compounds have relatively high vapor pressures, indicating that if spilled on the ground surface or present in soils near the ground surface, they would tend to rapidly volatilize. The relatively high aqueous solubilities of most compounds at the site indicate that the compounds are likely to dissolve into infiltrating precipitation and percolate to the groundwater table where they may be transported by advective flow of groundwater. The relatively high Henry's Law constants indicate that advectively transported compounds would tend to adsorb onto available organic carbon in the aquifer and move substantially more slowly than groundwater. Finally, the relatively high Henry's law constants of these compounds indicate that the compounds would tend to transfer from the aqueous phase to the gaseous phase if exposed to the atmosphere or to air in soil pore space.

### 5.2.3 Polycyclic Aromatic Hydrocarbons

PAHs are a group of organic chemicals containing two or more aromatic (benzene) rings that are produced during incomplete combustion of organic materials. PAHs are also present in asphalt used in road construction, crude oil, refined petroleum products, creosote, and roofing tar (Research Triangle Institute 1995). There are more than 100 PAHs. Those detected at IR Site 34 include benzo(a)anthracene, B(a)P, benzo(b)fluoranthene, chrysene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, indeno(1,2,3-c,d)pyrene, and naphthalene in soil; and B(a)P, dibenzo(a,h)anthracene, and naphthalene in groundwater. Of these, four are classified as probable human carcinogens, one is classified as a possible human carcinogen, and three are not classified.

The simplest PAH (naphthalene) contains two benzene rings, B(a)P contains four benzene rings, and other PAH compounds contain five or more benzene rings. In general, PAHs are hydrophobic compounds with low water solubility and high affinity for sorption to organic particles. Water solubility and Henry's Law values decrease with the increasing number of aromatic rings. Conversely,  $K_{oc}$  values for PAHs increase with the increasing number of aromatic rings (Morgan and others 1967). These general chemical characteristics of PAHs affect the environmental behavior of PAHs: naphthalene is the most mobile PAH and is most likely to

dissolve and be transported advectively with groundwater, while PAHs with more aromatic rings have a stronger tendency to sorb to soil and appear to persist longer in the environment (Morgan and Others 1990).

The biodegradation of PAHs is thought to become more difficult with increasing number of aromatic rings; high-molecular-weight, multiringed PAHs groups [such as B(a)P] are the most resistant to biodegradation and generally remain in soil longer than lower-molecular-weight PAHs with fewer aromatic rings (such as naphthalene) (Research Triangle Institute 1995).

Naphthalene consists of two benzene rings and the relatively high mobility of naphthalene results from its small size compared with other PAHs. Naphthalene is a constituent of diesel fuel and fuel oils and has been shown to biodegrade in soils. Naphthalene is the most volatile of the PAHs, and naphthalene has slight tendency to sorb to organic carbon in soils. Naphthalene also is the most water soluble of the PAHs.

Other PAHs are less soluble and more likely to sorb to organic carbon in soils. The four-, five-, and six-ring PAHs will likely accumulate in soils and sediment as a result of their tendency to strongly sorb to organic carbon (Kanaly and Harayama 2000). PAHs in soil can enter groundwater, although their low solubility in water and high affinity for sorption to soil greatly retard this process (Research Triangle Institute 1995). Although the low aqueous solubilities suggest that the four-, five-, and six-member ring PAHs will have low mobility in aqueous or soil environments, these larger PAHs may be transported in free-phase product such as diesel fuel or fuel oil.

In summary, PAHs in general have low aqueous solubility and high affinity for sorption to soils. The PAHs generally biodegrade very slowly. These properties make PAH compounds relatively persistent and immobile in the environment. Although classified as a PAH, naphthalene is the most soluble, most volatile, and least persistent of the PAHs.

#### **5.2.4 Pesticides**

Pesticides detected at IR Site 34 at concentrations exceeding comparison criteria include dieldrin and heptachlor epoxide, which were generally detected along fence lines or former fence lines at the site and may have historically been applied to control growth of weeds.

These chemicals are strong insecticides that generally persist in the environment. Their persistence, toxicity, and tendency to bioaccumulate led to the eventual banning of these insecticides for agricultural use. Low vapor pressures and Henry's Law values for these pesticides suggest that residues will not volatilize rapidly, and low aqueous solubilities indicate that the chemicals will not readily dissolve and be transported with groundwater (Howard 1991). The solubility of these insecticides may be enhanced by dissolved organic matter or mixtures of contaminants (co-solvent effect).

The  $K_{oc}$  for dieldrin and heptachlor epoxide data suggest these pesticides will sorb strongly to soil organic matter. Dieldrin has shown limited microbial degradation (Matsumura and Boush 1967). However, heptachlor epoxide is a metabolite of heptachlor, and the presence of heptachlor epoxide indicates that some biological degradation of heptachlor has occurred.

In summary, dieldrin and heptachlor epoxide are relatively stable compounds that are expected to be immobile and persistent in soils at IR Site 34.

### **5.2.5 Polychlorinated Biphenyls**

PCBs were detected at concentrations exceeding comparison criteria in soils at a number of locations at IR Site 34, including the western site boundary, between former Buildings 343 and 344, and around former Building 331. Isolated exceedances also were identified at former Building 604 and in off-site step-out samples near former Building 345. PCBs have excellent insulating properties, are nonflammable, and have been used widely in the past as coolants and lubricants, especially in electrical transformers. PCBs are among the most persistent manmade compounds in the environment, and can resist degradation for years (Agency for Toxic Substance and Disease Registry 2001). The manufacture of PCBs was halted in 1977 as a result of their bioaccumulation in the environment.

PCBs degrade slowly in soil in natural systems. PCBs have large molecular structures and typically bind to soil based on their size and physical characteristics. Anaerobic systems degrade PCBs more rapidly than aerobic systems. PCBs will likely persist at PCB-contaminated sites unless native microbial communities are augmented with specific microbes found to be effective in PCB degradation, or until native communities are enhanced through soil amendments.

The low mobility exhibited by these hydrophobic compounds slows their migration to groundwater, unless a mobilizing agent is introduced. At IR Site 34, PCBs are not expected to migrate to groundwater.

### **5.2.6 Petroleum Hydrocarbons**

Petroleum hydrocarbons are complex mixtures of straight-chain, branched, cyclic, and aromatic hydrocarbons that are typically analytically quantified as TPH in the diesel-, motor oil-, or gasoline-range. Petroleum hydrocarbons are normally used as fuels, solvents, or chemical intermediaries. At U.S. military bases, petroleum products are primarily used as fuels, and in limited cases, solvents.

In general, petroleum fuels are prepared by distillation that separates the hydrocarbon mixture into molecular weight fractions based on boiling point. Gasoline consists primarily of the lower-molecular-weight fractions, generally from C4 (four carbon alkane, butane) to C10 (decane), while diesel fuel and motor oil contain proportionally more higher-molecular-weight fractions that fall in the C10 to C20 range. Differences in chemical properties between the low-molecular-weight and high-molecular-weight fractions cause differences in behavior of TPH as diesel, as

motor oil, and as gasoline released to the surface or subsurface. The main chemical properties that affect the fate and transport of petroleum hydrocarbons are Henry's law constant, aqueous solubility, and sorption coefficient.

Henry's law constant is based on the equilibrium relationship between the solubility of a gas in water and the partial pressure of the gas in the atmosphere above the water. Henry's law constant represents the tendency of a dissolved gas to transfer from a dissolved phase to the atmosphere (Montgomery and Welkom 1989). Compounds present in petroleum hydrocarbons have variable Henry's Law constants. Lighter fractions of petroleum distillates—such as benzene, ethylbenzene, toluene, and xylene—tend to have high Henry's law constants, indicating the compounds would have a tendency to volatilize from aqueous solutions exposed to the atmosphere. Heavier-molecular-weight petroleum distillates such as PAHs tend to have lower Henry's Law constants and have a lesser tendency to volatilize from solution when exposed to the atmosphere.

Aqueous solubilities of petroleum hydrocarbons are variable with the low-molecular-weight hydrocarbons being somewhat soluble, while the higher-weight-hydrocarbons are less soluble (Williams and Others 2005). Because of the large differences in solubility, the lighter aromatic fraction of TPH (benzene, ethylbenzene, toluene, and xylenes) may dissolve and travel with groundwater as a dissolved phase, while the heavier-molecular-weight hydrocarbons may remain in the subsurface as a separate nonaqueous phase.

Sorption of petroleum hydrocarbons is an important fate and transport process.  $K_{oc}$  for the higher-molecular-weight hydrocarbon compounds are quite high, indicating that these compounds tend to adsorb to soils. Thus, heavier diesel-range compounds and motor oil-range compounds are expected to have a stronger tendency to adsorb to the surface of soils.

Many microorganisms in aerobic environments can use petroleum hydrocarbons as an energy source. As a result, biodegradation is probably the primary hydrocarbon removal mechanism in many aerobic soil and groundwater environments. In general, the biodegradation of petroleum products appears to be a successive process, with microorganisms first using the simple low-molecular-weight hydrocarbons, followed by higher-molecular-weight hydrocarbons. The larger four- and five-ring aromatic hydrocarbons such as PAHs appear to be biodegraded to a much lesser extent.

In summary, TPH as gasoline is expected to be the least persistent and most mobile of the three TPH fractions, and is likely to be present as a dissolved phase in groundwater. It is unlikely that TPH as gasoline will persist in soils for long periods. In contrast, TPH as motor oil is expected to be least likely to dissolve and most likely to adsorb to organic materials in soil, and thus is least likely to be present as a dissolved phase and most likely to remain adsorbed to soils. TPH as diesel is an intermediate hydrocarbon mixture that is expected to exhibit intermediate properties.

### 5.3 CONCEPTUAL SITE MODEL

This subsection summarizes the fate and transport of COIs at IR Site 34 as a CSM. The CSM is used to identify and prioritize pathways that pose the greatest potential effects to the environment. These pathways are considered further in the HHRA and SLERA presented in Sections 6.0 and 7.0.

IR Site 34 is currently unoccupied land and is considered part of the Northwest Territories. The Northwest Territories are designated as Public Open Space and Parks, and the planned reuse of this area is recreational (City of Alameda 2003). The future designated use of much of IR Site 34 is as part of a golf course (Alameda Reuse and Development Authority 2006).

Although the residential scenario was evaluated in the risk assessment to provide information to decision-makers, this scenario is unlikely for the site since the site is located in the tideland trust area where residential use is restricted. Chemicals present in soil and groundwater at IR Site 34 were summarized in Sections 4.1 and 4.2. The COIs include metals in soil and groundwater (primarily arsenic and manganese); VOCs in soil and groundwater (primarily TCE and its degradation products); PAHs in soil and groundwater; pesticides and PCBs in soil; and petroleum hydrocarbons in soil and groundwater (primarily diesel-range and motor oil-range hydrocarbons). As discussed above in Section 5.2, physicochemical properties of metals such as lead, PAHs, pesticides, and PCBs create a high probability that these contaminants will sorb to soils and become immobile.

Previous investigations indicated the most probable sources for most of the chemicals detected at IR Site 34 are sandblasting grit, waste paint material, transformers, ASTs, and chemical storage. Chemical concentrations in site soils do not indicate a likely spill area or a likely potential ongoing source of contamination. Chemicals released by these mechanisms may become dispersed from the initial site of the release by leaching from soils to groundwater by infiltrating rainwater, wind transport, entrainment with overland flow of surface water, and exfiltration from storm drains. Preferential groundwater flow pathways along utility lines also may be present. Based on the data collected from these two points and the chemical distribution at the site, it does not appear that chemicals are migrating along this pathway.

As discussed in Section 5.2 above, the primary transport pathways for contaminated soils are leaching to groundwater or direct transport of soils through wind erosion or overland flow of surface water and to a much lesser extent direct volatilization. The future reuse of the site as a golf course and park will reduce wind transport and entrainment with overland flow as chemical transport mechanisms from those portions of IR Site 34. Consequently, transport of contaminated soils by wind and water is expected to be reduced in the future, and leaching to groundwater is the pathway of most significance for contaminated soils.

Groundwater is affected by most of the chemicals present in site soils. As discussed in Section 4.2, concentrations of some chemicals in site groundwater exceeded comparison criteria, but are relatively low and do not indicate the presence of a continuing source of contamination or the presence of source material that should be addressed by a response action. Groundwater

contamination, where present, is characterized by diffuse and variable concentrations that do not indicate a primary area of release (see for example Figures 4-17 and 4-21).

In areas where natural TPH degradation in the groundwater is occurring, some metals in soil may become more soluble resulting in localized increases in their groundwater concentrations. At IR Site 34, TPH and several metals, including arsenic, iron, and manganese, were detected in groundwater at concentrations exceeding comparison criteria. However, these localized elevated concentrations are expected to return to background levels after the TPH has been completely degraded. The metals arsenic and manganese were detected in groundwater at the same general locations where TPH concentrations in soil are elevated (see for example the south and west sides of Building 331), suggesting microbial degradation of the petroleum hydrocarbons has consumed available oxygen in the subsurface and created local reducing conditions at these locations, which may have mobilized arsenic and manganese from soil to groundwater. Outside the zone where TPH is actively degrading microbially, oxidizing conditions will likely be encountered, which will transform the ionic species of arsenic and manganese to less soluble states, and reprecipitation of arsenic and manganese will likely occur.

In addition, TCE and its degradation products were detected in a diffuse groundwater plume covering the western half of the site. Observed concentrations in the TCE plume do not suggest that a continuing source area exists that should be addressed by a response action (see Figure 4-17). The presence of degradation products such as 1,2-DCE and vinyl chloride indicates that biodegradation is occurring within the TCE plume. Use of the site as a golf course is expected to reduce the potential for vapor migration by providing a greater thickness of soil between VOC-contaminated groundwater and the lower floor of new buildings or outdoor air.

As discussed in Section 2.4.2, groundwater at the IR Site 34 and surrounding sites generally flows from the center of the Alameda Point toward the shorelines of Seaplane Lagoon, San Francisco Bay, and Oakland Inner Harbor. At IR Site 34, limited available groundwater measurements from the five permanent monitoring wells at the site indicated that the site has a low hydraulic gradient and that groundwater flows from the center of the site toward the Oakland Inner Harbor with a northwestern component to the flow (see Figure 2-5). The shallow unconfined aquifer is composed primarily of fine, artificially deposited, estuarine sand fill with hydraulic conductivity characteristic of silty sands. The low hydraulic gradient and moderate hydraulic conductivity create relatively slow groundwater flow velocities. The estuarine nature of the fill material used to build Alameda Point suggests that organic carbon is likely present in the surficial aquifer, which will offer many sites for adsorption and further slow transport of chemicals through flowing groundwater. Slowly flowing groundwater with low concentrations of chemicals will ultimately discharge to Oakland Inner Harbor through subsurface recharge of surface water. The low-flow velocities of groundwater, low concentrations of chemicals in groundwater, high potential for retardation along the groundwater flow path, and tidal action and surface water flow that create a mixing zone at the interface with the Oakland Inner Harbor suggest that chemicals will not discharge to the Inner Harbor at concentrations of concern. The presence of utility corridors may create preferential flow pathways that allow more rapid flow of groundwater toward the Inner Harbor at a few locations.

The general CSM for IR Site 34 is that soils and groundwater are affected by a number of chemicals; however, the contaminants are not expected to migrate in a manner that could cause significant exposures to humans or the environment based on future use as a golf course and park. The primary chemical transport pathway would be leaching from infiltrating precipitation and transport via groundwater flow. Direct volatilization of chemicals is unlikely to represent a significant exposure pathway because VOC concentrations in groundwater are relatively low and residential use of the site is restricted because the site is located in the tideland trust area. Direct contact and entrainment of chemicals with surface runoff is expected to be mostly eliminated by the future reuse of the site as a golf course and park. Leaching and horizontal migration of chemicals in groundwater is considered a primary transport pathway for the site. The potential for chemicals to discharge to the Oakland Inner Harbor at concentrations of concern is mitigated by low concentrations of contaminants in groundwater, low flow velocities of groundwater, and high potential for retardation along the groundwater flow path.

#### 5.4 FATE AND TRANSPORT SUMMARY

A summary of the possible transport mechanisms considered for IR Site 34 is presented below.

- Particulate dispersion is the process by which chemicals are transported as airborne or waterborne particulates by wind erosion and surface runoff. Due to minimal surface cover at IR Site 34, soil erosion (as wind drift, sediment transport, and surface runoff) is a likely current transport mechanism. However, the significance of this transport mechanism is expected to be largely eliminated based on the reuse of the site as a golf course.
- Volatilization of organic chemicals from soil and groundwater is possible but probably not significant because of the relatively low levels detected in soil. Future reuse of the site as a golf course and park minimizes the possibility that direct volatilization of chemicals may represent a significant exposure pathway.
- Migration of chemicals in the subsurface caused by leaching from vadose zone soils into groundwater with infiltrating precipitation is considered a primary transport mechanism at the site. Because most of IR Site 34 is unpaved, the migration of chemicals caused by infiltrating precipitation is considered a likely transport pathway. Transport from soil to groundwater can also occur when seasonal or tidal fluctuations of groundwater elevation bring groundwater in contact with contaminated soil, allowing chemicals to dissolve into groundwater. However, the nature and extent of soil contamination discussed in Section 4.1 indicates that most of the soil contamination present at IR Site 34 is in shallow soils and outside the range of tidal fluctuations or seasonal variations in groundwater elevation, reducing the significance of water table fluctuations as a chemical transport mechanism.

- Groundwater in the surficial aquifer at IR Site 34 is present in unconfined conditions at depths ranging from approximately 2.4 to 4 feet bgs. Groundwater in the surficial aquifer is affected by most of the chemicals present in site soils, and horizontal migration of chemicals because of groundwater flow and tidal fluctuation is considered a primary transport pathway for the site. Groundwater at IR Site 34 and surrounding sites generally flows from the center of the Alameda Point toward the shoreline. The low-flow velocities of groundwater, low concentrations of chemicals in groundwater, high potential for retardation along the groundwater flow path, and tidal action and surface water flow that create a mixing zone at the interface with the Oakland Inner Harbor suggest that chemicals will not discharge to the Inner Harbor at concentrations of concern.
- Potential preferential flow pathways at IR Site 34 include a storm sewer line west of former Buildings 331, 345, and 471 and associated outfall; a storm sewer catch basin; and portion of a storm sewer line in the undeveloped western portion of the site that continues and empties through an outfall beyond IR Site 34 boundary. Migration of chemicals because of groundwater flow through subsurface conduits is considered a possible transport pathway for the site. However, based on the data collected from two borings next to the storm drain line (DP12 and DP17) and the chemical distribution at the site, it does not appear that chemicals are migrating along this pathway.
- Migration of groundwater to deeper aquifers is not considered a significant transport pathway at IR Site 34 because a thick clay aquitard layer underlies the surficial fill layer at the site. The only monitoring well screened in the deeper aquifer at IR Site 34 (MW-24) does not exhibit contamination by VOCs, although other regional chemicals such as pesticides and hydrocarbons have been detected at low concentrations in groundwater samples from this well.

## 6.0 BASELINE HUMAN HEALTH RISK ASSESSMENT

This section summarizes the risks estimated for future commercial/industrial workers, construction workers, residents, and recreational users at IR Site 34. Appendix H provides a detailed discussion of the risks in the HHRA, including the supporting calculations and the estimated risks for each COPC evaluated. Section 3.5 summarized the methodology used to estimate risks. The HHRA used a dual-tracking approach to consider both EPA and DTSC toxicity values. To satisfy federal (Navy and EPA) and state (DTSC) requirements, the HHRA prepared a set of risk assessment results using EPA toxicity values, and a separate set of risk assessment results using DTSC toxicity values. The HHRA estimated risks using EPA and DTSC toxicity values assuming both a RME scenario and a central tendency exposure (CTE) scenario. RME is intended to represent the upper end of exposure, whereas CTE represents an average exposure.

In the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), EPA defined general remedial action goals for sites in the National Priorities List (Title 40 of the *Code of Federal Regulations* Part 300.430). The goals included a range for residual cancer risk, which is "an excess upper bound life-time cancer risk to an individual of between  $10^{-4}$  and  $10^{-6}$ ," or 1 in 10,000 to 1 in 1,000,000. For that reason, the range between  $10^{-4}$  and  $10^{-6}$  is often referred to as the "risk management range". The NCP states "the  $10^{-6}$  risk level shall be used as the point of departure for determining remediation goals." Using this criteria as a general guide, the HHRA called a COPC a "risk driver" when the COPC-specific cancer risk exceeds  $1 \times 10^{-6}$  or the COPC-specific HQ exceeds 1. The RI Report evaluated each risk driver to determine whether it should be considered in an FS.

This HHRA calculated total risks, which include risks from background concentrations of metals, and incremental risks, which exclude risks from background concentrations of metals. The following section compares total risks with incremental risks. Sections 6.2 and 6.3 summarize the total risks (including background concentrations) to future workers, recreational users, and residents at IR Site 34. Section 6.4 evaluates the risk drivers identified in the HHRA as well as chemicals exceeding comparison criteria to determine whether they should be considered in an FS. Section 6.5 summarizes the analysis of uncertainties, and Section 6.6 presents the conclusions of the HHRA and the risk driver evaluations.

### 6.1 TOTAL AND INCREMENTAL RISKS

Two-population statistical tests were used to compare metals concentrations in IR Site 34 soil samples with background concentrations determined for Alameda Point. Appendix G describes the background comparison methods. Statistical tests determined that beryllium, mercury, and silver are less than background concentrations, and that all other detected metals are greater than background concentrations. To evaluate the contribution of background risks to the total risk estimates, the HHRA estimated incremental risks by calculating the risks from background concentrations of all metals detected in soil and subtracting the risks from background concentrations from the total risk estimates. Table 6-1 presents the total risks, the risks from background concentrations, and the incremental risks using EPA toxicity values. Table 6-2

presents the total risks, the risks from background concentrations, and the incremental risks using DTSC-preferred toxicity values. As shown in Table 6-1, except for the future construction worker, the incremental risks were similar to the total risks. Subtracting the contribution of background concentrations of chromium and manganese reduced the risks for the construction worker. However, the incremental cancer risk was still within the risk management range of  $10^{-4}$  and  $10^{-6}$ , and the noncancer HI estimate was still greater than the threshold HI of 1 for noncarcinogens. The following sections present the total risks, which include risks from background concentrations of metals, for future workers (commercial/industrial and construction), recreational users, and residents.

## 6.2 FUTURE WORKERS AND RECREATIONAL USERS

IR Site 34 is currently unoccupied land. Thus, no receptors are currently present at the site. The planned reuse of this area is recreational and includes the development of a golf course and park (City of Alameda 2003). Table 6-3 presents the RME and CTE risks using both EPA and DTSC toxicity values. Table 6-3 shows that RME and CTE cancer risks for future commercial/industrial and construction workers are within the risk management range of  $10^{-4}$  and  $10^{-6}$  using EPA toxicity values. Noncancer HI estimates under both the RME and CTE scenarios are greater than the threshold HI of 1 for noncarcinogens for future commercial/industrial workers. While the RME HI estimates are greater than 1 for future construction workers, the CTE HI estimates are less than 1 for future construction workers. Potential cancer risks under both the RME and CTE scenarios for recreational users were within the risk management range of  $10^{-4}$  and  $10^{-6}$  and the HI is equal to 1.

Table 6-4 presents the RME risks for each exposure pathway using EPA and DTSC toxicity values. Table 6-5 presents the CTE risks for each exposure pathway using EPA and DTSC toxicity values. These tables show that most of the potential risks to workers are associated with soil exposure pathways. Potential CTE and RME risks from groundwater exposure pathways for future workers and recreational users were less than  $1 \times 10^{-6}$  and noncancer HI estimates were less than 1. Section 6.4 discusses the risk drivers identified in soil for future workers and recreational users.

The potential for human health effects caused by lead is typically estimated on the basis of blood-lead concentrations. Although LeadSpread was designed to estimate blood-lead levels for occupational exposures, DTSC is not currently recommending the use of this model for assessment of exposure to lead under an occupational setting (DTSC 2005b). The lead EPCs for surface soil (0 to 2 feet bgs) and subsurface soil (0 to 4 feet bgs) were compared with the industrial PRG of 800 mg/kg for soil. Lead concentrations exceeded the EPA industrial PRG of 800 mg/kg in 7 soil samples, and lead concentrations were greater than the background concentration of 37.7 mg/kg in 45 samples (see Table 4-1).

### 6.3 FUTURE RESIDENTS

The HHRA evaluated potential risks for future residents. Residential development of IR Site 34 is unlikely because the planned future reuse of the area is a golf course and park. In addition, IR Site 34 has been identified as a tideland trust area that is subject to the limitations expressed in the Coastal Zone Management Act, including a restriction on residential use. Although future development of the site for residential use is hypothetical and unlikely, evaluation of this scenario provides alternative risk estimates for unrestricted reuse of the site and supports risk management decisions for the site. Table 6-3 presents the RME and CTE risks using both EPA and DTSC toxicity values. Table 6-3 shows that RME cancer risks to future residents are greater than  $10^{-4}$ . CTE cancer risks to future residents are greater than  $10^{-4}$  using DTSC toxicity values and within the risk management range of  $10^{-4}$  to  $10^{-6}$  using EPA toxicity values. The CTE and RME noncancer HI estimates are greater than the threshold HI of 1 using both EPA and DTSC toxicity values. These risk estimates, however, represent risk estimates for a hypothetical residential scenario that is unlikely. In addition, many conservative assumptions were used that may have overestimated the risks. For example, many of the VOCs accounting for most of the risks for the residential scenario are based on the maximum detected concentrations in only one soil sample (see Section 6.4.1.2).

Table 6-4 presents the RME risks for each exposure pathway using EPA and DTSC toxicity values. Table 6-5 presents the CTE risks for each exposure pathway using EPA and DTSC toxicity values. Using EPA toxicity values, Table 6-4 shows inhalation of indoor air from soil vapor intrusion accounts for 50 percent of the total cancer risk to future residents, and soil ingestion accounts for 22 percent of the total cancer risk. Inhalation of indoor air from soil vapor intrusion accounts for 74 of the total HI of 82. Using EPA toxicity values, the potential RME cancer risk and the noncancer HI from groundwater exposure pathways for future residents is  $5 \times 10^{-6}$  and 0.07, respectively. Using EPA toxicity values, the potential CTE cancer risk and the noncancer HI from groundwater exposure pathways for future residents is  $1 \times 10^{-6}$  and 0.05, respectively. Section 6.4 discusses the risk drivers identified in soil and groundwater for future residents.

The potential for human health effects caused by lead is typically estimated on the basis of blood-lead concentrations. The table below presents the estimated blood-lead concentrations.

Exposure Area	Lead EPC (mg/kg)	Predicted 99th Percentile Blood-Lead Concentration (µg/dL)	
		Adult Resident	Child Resident
Surface Soil (0 to 2 feet bgs)	2,900	111	29.5
Subsurface Soil (0 to 4 feet bgs)	2,390	92	24.5

Notes:

- 1 Soil assumed to be unprotected by pavement for this assessment
- µg/dL Microgram per deciliter
- bgs Below ground surface
- EPC Exposure point concentration
- mg/kg Milligram per kilogram

Blood-lead modeling resulted in 99th percentile concentrations greater than 10 µg/dL for the adult and child residents. Because blood lead modeling results exceeded 10 µg/dL, there is a potential for unacceptable harmful effects from exposure to lead. Lead was detected in 103 of 105 soil samples at IR Site 34. Lead concentrations ranged from 1.1 mg/kg to 21,000 mg/kg and the average was 520 mg/kg (see Table 4-1).

## **6.4 RISK DRIVERS**

The following sections discuss the risk drivers identified in soil and groundwater using EPA toxicity values. As described previously, when discussing risks in the HHRA, a COPC is termed a "risk driver" when the COPC-specific cancer risk exceeds  $1 \times 10^{-6}$  or the COPC-specific HQ exceeds 1. This section also compares the risk drivers identified in the HHRA with the chemicals exceeding comparison criteria as discussed in the nature and extent evaluation (see Section 4.0). This comparison was used to determine which chemicals should be considered in an FS. For example, this section examines the risk drivers that did not exceed EPA Region 9 residential PRGs as well as the chemicals that exceeded PRGs but were not identified as risk drivers.

### **6.4.1 Risk Drivers in Soil**

Risk drivers identified in soil include metals, VOCs, PAHs, SVOCs, pesticides, and PCBs. Table 6-6 identifies the risk drivers in soil for each receptor using EPA toxicity values. The following sections discuss the risk drivers identified in soil using EPA toxicity values.

#### **6.4.1.1 Metals**

The HHRA identified the following metals as risk drivers in soil: aluminum, arsenic, iron, lead, and manganese. These metals were detected in more than 90 percent of the soil samples, and two-population statistical tests determined these metals are greater than background concentrations (see Table 4-2).

Arsenic, iron, and lead were risk drivers that also exceeded PRGs. This RI Report recommends consideration of arsenic, iron, and lead in an FS. However, iron is only a risk driver under the residential scenario. As discussed previously, residential development of IR Site 34 is unlikely. Although iron is an essential nutrient, it has been shown to be toxic at high doses. EPA derived a provisional RfD toxicity value for iron based on a specific metabolic disorder (EPA 2004e). Incorporation of this RfD resulted in a chemical-specific HQ exceeding 1. The significance of this result is dubious because ongoing debate over this provisional RfD has not resulted in its incorporation into IRIS (EPA 2006).

Aluminum and manganese are risk drivers that did not exceed residential or industrial PRGs in soil. This is because these two metals were only risk drivers for the future construction worker, and the EPA Region 9 PRGs are not available for the construction worker scenario. Inhalation

of fugitive dust by a future hypothetical construction worker accounted for more than 95 percent of the total HI of these two metals. The estimated exposure from the inhalation of fugitive dust pathway is generally higher for construction workers than industrial workers. This is mostly because of the particulate emission factors (PEF), which relate chemical concentrations in soil to chemical concentrations in air that may be inhaled on site. The HHRA, for example, used a PEF of  $1 \times 10^6$  cubic meters per kilogram ( $m^3/kg$ ) for construction workers and  $1.32 \times 10^9 m^3/kg$  for commercial/industrial workers. The HHRA calculated concentrations in outdoor air by dividing soil concentrations by the PEF. Aluminum was detected above a background concentration of 13,960 mg/kg in 8 of 82 soil samples (see Table 4-1). Three of these samples exceeding background concentrations were collected at 7 feet bgs, which is below the depth to groundwater. Manganese was detected above a background concentration of 383 mg/kg in 11 of 82 soil samples (see Table 4-1). Historical activities and the distribution of aluminum and manganese concentrations exceeding background do not indicate aluminum and manganese are related to Navy activities at IR Site 34. Thus, the RI report does not recommend consideration of aluminum and manganese in an FS.

The maximum cadmium and vanadium concentrations exceeded residential PRGs. However, the HHRA used the 95UCL of the mean concentration to estimate potential risks, not the maximum detected concentrations. Based on the 95UCL, cadmium and vanadium are not risk drivers using EPA toxicity values. Cadmium only exceeded the residential PRG at 1 of the 105 sampling locations and vanadium at 4 of the 105 sampling locations. The RI Report does not recommend consideration of cadmium and vanadium in an FS.

#### **6.4.1.2 Volatile Organic Compounds**

The HHRA identified the following VOCs as risk drivers in soil: 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and 1,4-DCB. All five of these VOCs were only detected once and at the same location (DP2). More than 90 percent of the estimated risks for these VOCs are from the vapor intrusion pathway. As shown in Table 4-1, except for 1,4-DCB, these VOCs did not exceed PRGs in soil. This is because EPA Region 9 does not incorporate the vapor intrusion pathway when calculating PRGs for residential soil, and the vapor intrusion pathway accounts for most of the risks for these VOCs.

As described above, all five of these VOCs were only detected once and at the same location (DP2). Thus, the estimated risks for these VOCs are not representative of site-wide conditions, but rather represent the potential risks at only one soil sampling location (DP2). In addition, many of the exposure assumptions used to estimate indoor air concentrations are highly conservative and may have overestimated risks. For example, risks estimated for the vapor intrusion pathway are based on the conservative assumption that future residential and industrial buildings will be constructed at the sampling locations with the highest VOC concentrations. As discussed previously, the planned future use at IR Site 34 is a golf course and park. Residential development of IR Site 34 is unlikely. Although the estimated risks for the five VOC risk drivers is overestimated, the RI Report recommends consideration of these risk drivers in an FS because they are collocated with PCBs that are also recommended for consideration in an FS.

Although consideration of these VOCs in an FS is recommended, the risk estimates are overestimated and are for a hypothetical residential scenario that is unlikely.

#### **6.4.1.3 Semivolatile Organic Compounds**

The only SVOC identified as a risk driver in soil was bis(2-ethylhexyl)phthalate. Bis(2-ethylhexyl)phthalate was identified as a risk driver but did not exceed PRGs. Most of the risk for bis(2-ethylhexyl)phthalate is estimated from the ingestion of homegrown produce pathway, which is not a pathway that EPA considers when calculating PRGs. Ingestion of homegrown produce is a very unlikely exposure pathway since residential development at IR Site 34 is not planned. In addition, the HHRA used a conservative model to estimate plant uptake of bis(2-ethylhexyl)phthalate from soil. Bis(2-ethylhexyl)phthalate was detected in 5 of 38 soil samples collected at IR Site 34. The highest detected concentration of bis(2-ethylhexyl)phthalate (25 mg/kg) was detected in a sediment sample from AA-IT001, which is located in the northeast portion of the site. The next highest detected concentration of bis(2-ethylhexyl)phthalate was 14 mg/kg in a surface soil sample collected at location 018-004-020, which is located in the southwest portion of the site. This location is not collocated with other chemicals exceeding comparison criteria. The remaining detected concentrations of bis(2-ethylhexyl)phthalate ranged from 0.031 to 0.078 mg/kg from samples collected in the southwest corner of the site. The potential risk from bis(2-ethylhexyl)phthalate is likely overestimated. The RI Report does not recommend consideration of bis(2-ethylhexyl)phthalate in an FS.

#### **6.4.1.4 Polycyclic Aromatic Hydrocarbons**

The HHRA identified the following PAHs as risk drivers: benzo(a)anthracene, B(a)P, benzo(b)fluoranthene, dibenzo(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene. These PAHs were all detected in more than 35 percent of the soil samples and exceeded residential PRGs. Except for naphthalene, these risk drivers were identified as risk drivers based on the estimated cancer risk using EPA toxicity values. When evaluating carcinogenic PAHs, this RI Report used a screening level of 0.62 mg/kg for an average B(a)P-equivalent concentration. This criterion is based on previous agreements between the Navy and regulatory agencies (Navy 2001b). The average EPA B(a)P-equivalent concentration (0.47 mg/kg) and OEHHA B(a)P-equivalent concentration (0.52 mg/kg) are below the established screening level of 0.62 mg/kg. The site-wide average concentration is influenced by an EPA B(a)P-equivalent value of 8.4 mg/kg and an OEHHA B(a)P-equivalent value of 9.5 mg/kg in a sample of anomalous soil collected above a black clayey sand with a strong diesel odor at location DP16. The site-wide average EPA and OEHHA B(a)P-equivalent concentrations without this sample are 0.023 and 0.25 mg/kg. The wide range of concentrations for the B(a)P equivalent (and for individual PAHs) is indicative of fill at the facility rather than a release at IR Site 34. Elevated concentrations of PAHs were confined to individual sample locations and do not appear to represent large masses of contaminated media. Thus, the RI Report does not recommend further consideration of PAHs in an FS.

Naphthalene exceeded the California-modified residential PRG and was identified as a risk driver. The risk from naphthalene is based on the maximum detected concentration in one sampling location (DP16). Thus, estimated risks for naphthalene is not representative of site-wide conditions, but rather represent the potential risks at only one soil sampling location. The sample collected from this location was analyzed by three different analytical methods. The naphthalene concentration in this sample was 4.8 mg/kg using EPA analytical method 8270C-SIM, 13 mg/kg using EPA analytical method 8270C, and it was not detected using EPA analytical method 8260 with a detection limit of 0.0047 mg/kg. The difference in concentrations is probably related to the heterogeneity of the soil sample. Although the risk from naphthalene is overstated, naphthalene is recommended for consideration in an FS because it is collocated with PCBs that are also recommended for further consideration in an FS.

Benzo(k)fluoranthene and chrysene exceeded PRGs but were not identified as risk drivers using EPA toxicity values. While the maximum detected concentrations of benzo(k)fluoranthene exceeded the residential PRG, the 95UCL did not. The HHRA used EPCs based on the 95UCL to estimate risks. Chrysene exceeded the Cal/EPA-modified residential PRG, but not the EPA residential PRG. Chrysene would be a risk driver using DTSC toxicity factors.

#### **6.4.1.5 Pesticides**

Using EPA toxicity values, the HHRA identified dieldrin, and heptachlor epoxide as risk drivers. Dieldrin and heptachlor epoxide exceeded residential PRGs and were both detected in 14 of 95 soil samples. Dieldrin and heptachlor epoxide were only risk drivers for the residential scenario. As discussed previously, residential development of IR Site 34 is unlikely. Although consideration of dieldrin and heptachlor epoxide in an FS is recommended, the risk estimates for these two pesticides are for a hypothetical residential scenario that is unlikely.

#### **6.4.1.6 Polychlorinated Biphenyls**

Using EPA toxicity values, the HHRA identified Aroclor-1248, Aroclor-1254, and Aroclor-1260 as risk drivers. While Aroclor-1254 and Aroclor-1260 were detected in more than 20 percent of the samples, Aroclor-1248 was detected in only 3 of 143 soil samples. These three PCBs exceeded residential PRGs. The maximum detected concentrations of another PCB, Aroclor-1268, also exceeded residential PRGs, but was not identified as a risk driver because the HHRA used an EPC based on the 95UCL, not the maximum detected concentration. Because maximum detected concentrations of Aroclor-1248, Aroclor-1254, Aroclor-1260, and Aroclor-1268 are collocated, the RI Report recommends consideration of these four PCBs in an FS.

### **6.4.2 Risk Drivers in Groundwater**

The only risk driver identified in groundwater using EPA toxicity values is TCE. Potential risks from TCE are within the risk management range of  $10^{-4}$  to  $10^{-6}$ . TCE was only a risk driver for future residents. As discussed previously, residential development of IR Site 34 is unlikely. Many of the exposure assumptions used to estimate risks for VOCs were conservative and may

have overestimated risks. The vapor intrusion pathway, for example, accounted for 98 percent of the estimated cancer risk for TCE and the vapor intrusion model (EPA 2004b) used to estimate indoor air concentrations produces highly conservative results (see Section 6.5). In addition, the HHRA used conservative assumptions to estimate the groundwater EPCs, which were used in the vapor intrusion modeling. Grab groundwater samples were used to estimate EPCs in groundwater. TCE was detected in 8 of 30 groundwater samples. The two highest TCE concentrations (0.6 µg/L) were detected in grab groundwater samples collected using direct-push technologies. The highest TCE concentration detected in a monitoring well was an estimated value (J-qualified) of 0.2J µg/L, which was less than the reported detection limits. The HHRA used an EPA oral and inhalation SF of 0.4 (mg/kg-day)<sup>-1</sup>, which is a provisional value from the National Center for Environmental Assessment as presented in the EPA Region 9 PRG table (EPA 2004e). Section 6.5 further discusses uncertainties associated with toxicity values. Thus, no further evaluation of groundwater is required and no action is recommended.

As summarized in Section 4.2, many other chemicals besides TCE exceeded comparison criteria for groundwater such as EPA tap water PRGs. EPA Region 9 based tap water PRGs on the inhalation and ingestion of domestic water. However, as discussed in Section 2.5, groundwater at IR Site 34 is not reasonably anticipated to serve as a public drinking water supply. Accordingly, the HHRA did not quantitatively evaluate domestic use of groundwater because it considers it to be an incomplete pathway. Groundwater exposure pathways considered in the HHRA included inhalation of indoor air from groundwater vapor intrusion and inhalation of outdoor air from chemicals volatilizing from groundwater to outdoor air.

## 6.5 UNCERTAINTY ANALYSIS

Varying degrees of uncertainty at each stage of the HHRA arise from assumptions made in the risk assessment and the limitations of the data used to calculate risks. Uncertainty and variability also are inherent in the exposure assessment, toxicity values, and risk characterization. The uncertainties fall into two categories: uncertainties associated with the general risk assessment methods, and site-specific uncertainties associated with the HHRA. This section discusses some of the site-specific uncertainties associated with the HHRA. Section H9.0 of Appendix H provides additional detail on uncertainties associated with the risk assessment.

**EPCs.** For many sampling locations, the collection of samples was biased toward areas with known or suspected contamination, rather than collecting samples at equidistant intervals throughout the site. EPCs based on these biased soil and groundwater samples are likely to overestimate the concentrations at the exposure point. In addition, the maximum detected concentrations were used as EPCs for data sets with fewer than four detected measurements. This may overestimate the risks because the HHRA assumes a potential receptor will be exposed to all of these localized hot spots even though the maximum detected concentrations are not all collocated.

**Vapor Intrusion.** The HHRA used EPA's advanced vapor intrusion models for soil and groundwater to estimate indoor air concentrations from concentrations of volatile COPCs in soil and groundwater. Exposure assumptions used in the vapor intrusion model are conservative and

may overestimate risks. For example, the HHRA used the maximum detected concentrations for many VOCs as EPCs, and assumed that a future building would be constructed at the location where the maximum concentrations of volatile COPCs in soil and groundwater were detected and that exposure to all volatile COPCs from vapor intrusion occurs concurrently, even when maximum concentrations are not collocated. In addition, the vapor intrusion models assumed steady-state concentrations of volatile COPCs in the subsurface for the entire duration of exposure (25 years for future hypothetical commercial/industrial workers and 30 years for future hypothetical residents). The assumption of steady-state concentrations for extended durations is conservative because, over time, chemicals may migrate from one medium to another or from one location to another within a particular medium. In addition, the assumption of steady-state concentrations for the entire duration of exposure assumes that reductions in concentrations that would likely occur through transformation or degradation processes—such as hydrolysis, photolysis, and biodegradation—do not occur. Evans and Bedient (1995) concluded that the use of steady-state methods may over predict risk by as much as two orders of magnitude.

**TCE.** The HHRA used an EPA oral and inhalation SF of  $0.4 \text{ (mg/kg-day)}^{-1}$ , which is a provisional value from the National Center for Environmental Assessment as presented in the EPA Region 9 PRG table (EPA 2004e). EPA withdrew its previously published toxicity values from EPA's IRIS database in 1988 and has not published finalized toxicity values for TCE since the original values were withdrawn because of uncertainties relating to the science of TCE toxicity. In 2001, EPA's Office of Research and Development completed a preliminary draft reassessment of health risks posed by TCE (EPA 2001c). This preliminary draft reassessment proposes toxicity values that are much more conservative than the values withdrawn by EPA, and these suggested toxicity values are now the subject of much debate. As such, the scientific community is divided on whether to use the withdrawn values, the new suggested values, or some other values for calculating risks. EPA's National Center for Environmental Assessment has recommended several SFs for TCE, with most between  $2 \times 10^{-2}$  and  $4 \times 10^{-1}$  per mg/kg-day. The range of SFs has not been reduced to a single number, but EPA's National Center for Environmental Assessment recommends that risk assessors use the upper-end of the SF range (that is,  $4 \times 10^{-1}$  per mg/kg-day) to emphasize the possibility that different risks may exist under different circumstances. The use of the upper end of the range of SFs is conservative and may result in an overestimation of risks.

## 6.6 CONCLUSIONS

For future hypothetical workers and recreational users, potential cancer risks from groundwater exposure pathways were less than  $1 \times 10^{-6}$  and noncancer HI estimates were less than 1. Total cancer risks under the RME scenario from soil exposure pathways were greater than  $10^{-4}$  for commercial/industrial workers and were within the risk management range of  $10^{-4}$  to  $10^{-6}$  for construction workers. The total HI estimates under the RME scenario from soil exposure pathways were greater than 1 for future hypothetical workers and recreational users. For future residents, potential cancer risks from groundwater exposure pathways were within the  $10^{-6}$  to  $10^{-4}$  range for carcinogens and the HI estimates were less than 1. Total cancer risks under the RME scenario from soil exposure pathways exceeded the risk management range of  $10^{-4}$  to  $10^{-6}$  for carcinogens, and the total HI estimates were greater than 1 for future residents. As discussed

previously, the planned future use at IR Site 34 is a golf course and park. Residential development of IR Site 34 is unlikely.

The table below presents the chemicals recommended for further consideration in an FS based on the evaluation of the risk drivers presented in Section 6.4.

Chemicals in Soil Recommended for Further Consideration in an FS			
1,2,3-Trichlorobenzene	1,4-DCB	Aroclor-1260	Iron
1,2,4-Trichlorobenzene	Aroclor-1268	Arsenic	Lead
1,2,4-Trimethylbenzene	Aroclor-1248	Dieldrin	Naphthalene
1,2-DCB	Aroclor-1254	Heptachlor epoxide	

Although the RI report recommends the chemicals listed above to be considered in an FS, potential risks from these chemicals are based on very conservative assumptions that may have overestimated risks and are for hypothetical residential scenarios that are unlikely. For example, 1,2,3-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and iron were only risk drivers under the residential scenario. As discussed previously, residential development of IR Site 34 is unlikely. In addition, potential risks estimated for many of the chemicals listed above may have been overstated. For example, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and 1,4-DCB risk drivers were only detected once. Thus the estimated risks for these chemicals are not representative of site-wide conditions, but rather represent the potential risks at only one soil sampling location.

**TABLES**

---

**Table 6-1: Total, Incremental, and Background Risks by Pathway, Reasonable Maximum Exposure, Using EPA Toxicity Sources**

Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Exposure Pathway	Total EPA Cancer Risk	Cancer Risk from Background Concentrations	Incremental Cancer Risk (total - background)	Total EPA Hazard Index	Hazard Index from Background Concentrations	Incremental Hazard Index (total - background)
<b>Residential Child + Adult (0-2 ft bgs)<sup>a</sup></b>						
Ingestion of soil	6E-05	9E-06	5E-05	5	1	4
Dermal contact with soil	2E-05	9E-07	2E-05	0.6	0.02	0.6
Ingestion of homegrown produce	6E-05	3E-06	6E-05	2.1	0.3	1.8

## 7.0 SCREENING-LEVEL ECOLOGICAL RISK ASSESSMENT

A SLERA was conducted as part of this RI Report to assess potential risk posed to ecological receptors from chemicals in soil and groundwater at IR Site 34. The SLERA followed Tier 1 of the Navy policy for conducting ERAs (Navy 1999a, 2001b), which is similar to Steps 1 and 2 of the ERA Guidance for Superfund sites (EPA 1997b). This approach used data collected during previous investigations at IR Site 34 (see Section 1.3.4) and conservative assumptions on chemical exposure to evaluate whether detected chemicals pose a potential risk to ecological receptors. In Step 1, Exposure Evaluation, potentially complete exposure pathways are examined to determine if links between site chemicals and ecological receptors exist at IR Site 34. Step 2, Risk Characterization, estimates risk based on the hazard quotient (HQ) approach. If the data evaluated in Steps 1 and 2 indicate risk to receptors at IR Site 34, then the Navy initiated the risk refinement step (Step 3a) of the baseline ERA.

The methodology used to conduct the SLERA for IR Site 34 is summarized in Section 3.6 and described in detail in Appendix I. The following subsections summarize the results and conclusions of the SLERA.

### 7.1 EXPOSURE EVALUATION

Exposure evaluation is Step 1 of the eight-step ERA process described in Section 3.6. The goal of the exposure evaluation is to develop an ecological CSM that addresses:

- Environmental setting and COPECs
- Chemical fate and transport mechanisms
- Mechanisms of eco-toxicity (broad classes of COPECs)
- Potentially complete exposure pathways

The ERA process begins with an assessment of site characteristics and ecological habitats, representative organisms, and threatened and endangered species that exist or have the potential to exist at the site. IR Site 34 is 4.18 acres of open space located on the northwestern portion of Alameda Point and is bordered to the north by the Oakland Inner Harbor. The primary land use is industrial. All of the site buildings have been demolished and most of the site is paved. IR Site 34 consists of intensively developed area, which has little vegetation and less foraging habitat than is available in surrounding areas, and two potential wetland areas. Appendix I has a more detailed discussion of the potential wetlands. Land use within a 1 mile radius of the site is mostly urban, with open space, wetlands, and the Oakland Inner Harbor comprising the remaining areas. The planned future use of the site is a golf course. For the purposes of the problem formulation it was assumed that future habitat would take the form of urban vegetation (grass and ornamental trees and shrubs).

Although wetland habitat is present within a 1 mile radius of the site, the areas do not meet the habitat requirements of special-status wildlife. Also, based on a review of the California Natural Diversity Database (2007), special-status plant and animal species are not expected to occur at IR Site 34.

The analytical data gathered during previous site investigations were used to select COPECs. The previous investigations at IR Site 34 indicated metals, PAHs, pesticides, PCBs, and TPH are present in soil, and metals, VOCs, PAHs, and TPH are present in groundwater (see Section 1.3.4). Tables 7-1 and 7-2 present the soil and groundwater COPECs.

As part of the fate and transport evaluation, the physical and chemical properties of the COPECs were evaluated. Based on these properties, all of the COPECs, except for VOCs, could bind preferentially to the soil and are relatively insoluble in water. The major movement of COPECs would be through erosion processes (such as wind and surface water runoff); infiltration to subsurface soil and groundwater; and groundwater discharge to surface water. In addition to the physical transport mechanisms, metals, PAHs, pesticides, and PCBs can bioaccumulate in terrestrial food chains.

No soil pathways for VOCs were quantitatively evaluated in this SLERA for several reasons. Toxicity reference values (TRV) are not typically available to evaluate the risk of dietary ingestion, so assessing risk related to VOCs is difficult. Since VOCs volatilize rapidly and do not bioaccumulate, risk from VOCs in soil is generally insignificant. Although inhalation modeling may be used to evaluate inhalation risk; VOCs were not considered to pose a significant threat since the detection frequency of these chemicals is low.

The following complete soil exposure pathways were identified for the COPECs at IR Site 34:

- Direct exposure to soil
- Food chain exposure

The following complete groundwater exposure pathway was identified for the COPECs at Site 34:

- Indirect exposure of aquatic life to groundwater through groundwater migration to the Oakland Inner Harbor

Groundwater at IR Site 34 and surrounding sites generally flows from the center of the Alameda Point toward the shoreline. The low-flow velocities of groundwater, low concentrations of chemicals in groundwater, high potential for retardation along the groundwater flow path, and tidal action and surface water flow that create a mixing zone at the interface with the Oakland Inner Harbor suggest that chemicals will not discharge to the Inner Harbor at concentrations of concern. Even though chemicals are not expected to discharge into the Oakland Inner Harbor, groundwater COPECs were qualitatively evaluated to generate conservative estimates of the

potential effects on aquatic life. See Appendix I for further discussion on selection of complete pathways for Site 34.

Unlike HHRAs, which evaluate only one species, the ERA involves multiple species with different degrees of exposure and toxicological responses. Ecological resources may be considered to be valuable when (1) their absence would significantly impair the function of the ecosystem; (2) they provide critical resources, such as habitat or fisheries; or (3) they are perceived as being valuable such as endangered species. Useful assessment endpoints define both the valuable ecological entities at the site and a characteristic of the entity to protect such as reproductive success or reproduction per unit area. An assessment endpoint is defined by EPA as an "explicit expression of an environmental value to be protected" (EPA 1997b).

Assessment endpoints are usually not amenable to direct measurement. Instead, endpoints that are measurable and related to assessment endpoints must be developed. Since there is relatively little information about adverse effects on specific ecological receptors, a generic assessment endpoint was formulated for the SLERA: sufficient rates of survival, growth, and reproduction to sustain wildlife populations typical to the area.

Although assessment endpoints are useful for the identification of general population goals, they do not provide a means for direct measurement or quantification of effects. Therefore, measurement endpoints were developed for IR Site 34. Measurement endpoints are defined as measurable ecological characteristics that are related to the characteristic chosen as the assessment endpoint and that are measures of biological effects (such as mortality, reproduction, growth) (EPA 1997b). These endpoints measured the biological effects to reproduction and physiology for the following ecological receptors at IR Site 34:

- California ground squirrel
- Deer mouse
- Alameda song sparrow
- American robin
- Red-tailed hawk
- Aquatic receptors

Additional information on problem formulation is provided in Appendix I.

## **7.2 RISK CHARACTERIZATION**

The second part of the SLERA is the preliminary risk characterization, Step 2.

## ***Terrestrial Wildlife***

Risk calculations for each terrestrial receptor were prepared, which allowed for a quantitative estimation of risk based on exposure assumptions for the individual receptor. For each measurement endpoint and COPEC, a conservative estimate of the dose to an organism was developed using soil EPCs and either site-specific or literature-derived exposure parameters. Using risk calculations, doses were then compared with TRVs to evaluate potential risk to each ecological receptor, and a HQ (a ratio that is indicative of potential risks to ecological receptors) was derived.

For this SLERA, both a low TRV and a high TRV were used wherever possible. Using the high and low TRVs to evaluate ecological receptors provides a bounding estimate of risk to each receptor. The high TRV represents an upper bounding limit, which is the lowest concentration at which adverse effects are known to occur. The low TRV represents the lower bounding limit, which is the highest concentration a receptor can be exposed to which adverse effects are known not to occur. If the hazard quotient is greater than 1, there is assumed to be significant risk. However, if the hazard quotient is less than or equal to 1, the risk is considered to be minimal. The entire exposure estimate and risk calculations are presented in Appendix I.

The results of the SLERA (Step 2) indicated that metals, some SVOCs and PAHs, pesticides, and PCBs in soil yielded HQs greater than 1, indicating the potential for unacceptable ecological risk (see Table 7-3). No TRVs were available for iron and 9 SVOCs (see Table 7-3). The soil COPECs with the highest HQ values were lead (61,000), Aroclor-1254 (4,780), Aroclor-1248 (1,200), and Aroclor-1260 (853). Most of the COPECs only exceeded the low TRV. Seven metals, 2 SVOCs, 4 pesticides, and 4 PCBs exceeded both the low and high TRVs, but the exceedances of the high TRV were never more than 2 orders of magnitude. The only two chemicals to greatly exceed both the low and high TRVs were lead and Aroclor-1248.

## ***Aquatic Life***

For the qualitative evaluation of aquatic life, groundwater COPECs were compared to four sets of primary aquatic comparison criteria potentially applicable to the site. Based on the results of the qualitative evaluation for groundwater, the following COPECs, which either exceeded the aquatic comparison criteria or no criteria were available, were retained for further evaluation (see Table I-23 in Appendix I):

- Metals: aluminum, arsenic, cobalt, copper, manganese, mercury, nickel, and zinc
- VOCs: 2-hexanone, 4-methyl-2-pentanone, carbon disulfide, trans-1,2-DCE, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, isopropylbenzene, tert-butylbenzene, n-butylbenzene, n-propylbenzene, p-isopropyltoluene, and sec-butylbenzene
- PAHs: benzo(a)anthracene, B(a)P, benzo(b)fluoranthene, chrysene, and indeno(1,2,3-c,d)pyrene

- Pesticides: 4,4'-DDE, aldrin, beta-BHC, endrin aldehyde, heptachlor epoxide, alpha-BHC, and alpha-chlordane

No aquatic comparison criteria were available for aluminum, magnesium, manganese, 1,2,4-trimethylbenzene, 1,3,5-trimethylbenzene, 2-hexanone, 4-methyl-2-pentanone, carbon disulfide, isopropylbenzene, tert-butylbenzene, n-butylbenzene, n-propylbenzene, p-isopropyltoluene, sec-butylbenzene, trans-1,2-dichloroethene, alpha-BHC, and Beta-BHC.

### **7.3 STEP 3A RISK REFINEMENT**

In order to generate a slightly more realistic estimate of risk, while maintaining the conservative nature of the SLERA a Step 3a risk refinement was conducted. To further evaluate the COPECs that yielded HQs greater than 1 and a frequency of detection of 5 percent or greater, COPECs without TRVs, and groundwater COPECs that exceeded the four sets of aquatic threshold criteria, refined exposure estimates were developed.

#### **7.3.1 Risk Refinement for Terrestrial Wildlife**

Refined risk estimations were prepared for all soil COPECs yielding HQs greater than 1 and with a frequency of detection of 5 percent or greater. Refined risk estimates were not prepared for the following chemicals with HQs greater than 1 because their frequency of detection is less than 5 percent: pesticides (4,4'-DDD, aldrin, delta-BHC, dieldrin, endosulfan II, endosulfan sulfate, endrin aldehyde, endrin ketone, and technical chlordane) and PCBs (Aroclor-1248). HQs were also not prepared for the following chemicals because there were no TRVs: metals (iron); SVOCs (2,4-dimethylphenol, 4-methylphenol, 4-nitrophenol, 4-nitroaniline, dibenzofuran, di-n-butylphthalate, isophorone, and phenol); and pesticides (methoxychlor). Of those chemicals without TRVs, all but dibenzofuran, di-n-butylphthalate, isophorone, and phenol had a frequency of detection of less than 5 percent. Those chemicals in soil without TRVs were qualitatively evaluated.

The refined exposure estimates (Step 3a) only affected the red-tailed hawk, as the home ranges of all other receptors were smaller than the area of IR Site 34. All other exposure factors remained unchanged, maintaining the conservative nature of the screening-level exposure estimates. Several chemicals yielded refined HQs less than 1 (4 metals, 4 PAHs), indicating that ecological risk for these chemicals is minimal (see Table 7-4). Several chemicals yielded refined HQs greater than 1 (11 metals, 2 SVOCs, 2 PAHs, 2 pesticides, and 3 PCBs); therefore, these chemicals may pose an unacceptable risk to ecological receptors at IR Site 34. The COPECs with the highest refined HQ values are cadmium (140), lead (8,590), di-n-butylphthalate (103), and Aroclor-1254 (174).

Appendix I presents the detailed review of the HQs and the nature and extent of the remaining COPECs. Based on the results of further evaluation of the remaining COPECs, the following soil ecological risk driver was identified at IR Site 34:

- Lead

As discussed in Section 4.1, lead-contaminated soil appears to be present in several clusters near the former railroad track at the northwest corner of the site, around former Buildings 331, 343, 344, and 475, above the storm sewer, and isolated locations in the southwest corner of the site.

### 7.3.2 Risk Refinement for Aquatic Life

Qualitative evaluations were conducted chemical-by-chemical for those chemicals in groundwater retained from the initial screening. The evaluations included a comparison of the 95UCL and maximum concentrations of the retained COPECs to the threshold criteria, a supplemental literature search for additional criteria, consideration of sampling locations (for example, FWBZ versus SWBZ, at locations with other elevated metals), consideration of sampling dates, consideration of sample collection methods (for example, monitoring well versus direct push), and the groundwater data set (for example, EPC driven by outlier). Additional details of this qualitative evaluation are discussed in Section I6.1.2 of Appendix I, and a summary of these evaluations is presented in Table I-24 in Appendix I. No risk drivers were identified for groundwater at IR Site 34.

## 7.4 UNCERTAINTY

The SLERA process involves a large number of uncertainties and extrapolations to evaluate potential risk to ecological receptors. Many of the assumptions in the SLERA process are conservative and result in overestimates of site-specific parameters. Uncertainties associated with the SLERA conducted at IR Site 34 are identified below.

- **SUFs** – Risk calculations assumed that all of the receptors' home ranges were no larger than the site. The refined risk calculations assumed that only the small mammals and passerine ranges were no larger than the site.
- **Dietary Composition** – Receptor food composition and ingestion rates were based on literature studies and were not site-specific.
- **Bioavailability** – All COPECs were assumed to be 100 percent bioavailable to all receptors.
- **Development of TRVs** – TRVs used in risk calculations were derived from literature studies. These studies were not conducted on the receptors used in this assessment. TRVs were extrapolated using uncertainty factors to account for difference between species.
- **Qualitative Evaluations of COPECs** – Studies were not available to develop TRVs for a number of ecological receptors. Groundwater COPECs were only qualitatively evaluated.

- **Surrogate TRVs** – Surrogate TRV values were used for some chemicals, such as the use of a chlordane TRV for heptachlor and heptachlor epoxide because they are breakdown products of chlordane.

## 7.5 CONCLUSIONS

The SLERA intentionally incorporates conservative assumptions to identify any potential risk from site-related chemicals to ecological receptors. As a result, this assessment likely overestimates the risk associated with the COECs at IR Site 34. The refined risk estimation also likely overestimated risk, as many of the assumptions used in the initial risk estimation remained unchanged in the refined risk estimation.

Based on the results of the Step 3a risk refinement, the following chemical was identified as a risk driver in soil at IR Site 34.

- Lead

No risk drivers were identified in groundwater at Site 34.

Although lead may contribute to ecological risk at IR Site 34, based on the SLERA, a baseline ERA is not recommended because the SLERA likely overestimated risk, there is a lack of current suitable habitat, and future land use would not generate much ideal habitat for wildlife. IR Site 34 currently consists of predominantly Intensively Developed area and two potential wetland areas. Intensively Developed areas have little vegetation and typical urban wildlife, such as California ground squirrel, scrub jays, and American robins, may be observed in these areas but to a lesser extent than in the landscaped/developed areas, because less foraging habitat is available in these areas. The potential wetland areas provide minimal habitat to support plant and invertebrate populations and do not provide suitable habitat for small mammals. In addition, because of high marine vessel activity in the Oakland Inner Harbor it is unlikely that this area will be used by nesting birds.

Site-related chemicals in soil and groundwater at IR Site 34 are not expected to affect the potential wetland areas or the Oakland Inner Harbor for the following reasons. It is unlikely that groundwater or surface water runoff from IR Site 34 would affect the potential seasonal wetland located within the southwest corner of the site because the site topography would prevent it from reaching this potential wetland. Although surface water generally flows towards the wetland located to the north of the site, precipitation typically evaporates into the atmosphere, infiltrates to groundwater, or runs off into the storm drain system. The potential wetland is also not likely to be affected by site-related chemicals in groundwater because it lies between a series of parallel rock riprap walls that together form a terrace of land that is the shoreline and is tidally inundated at such a frequency as to not present suitable habitat for small mammals, dilution would occur as groundwater mixes with surface water (Oakland Inner Harbor), and groundwater COPECs were identified based on the assumption that no dilution, retardation, or degradation will occur between the location where the groundwater risk drivers were detected and the Oakland Inner Harbor/wetland. In addition, the low-flow velocities of groundwater, low concentrations of

VOCs in groundwater, high potential for retardation along the groundwater flow path, and tidal action and surface water flow that create a mixing zone at the interface with the Oakland Inner Harbor suggest that chemicals will not discharge to the Oakland Inner Harbor at concentrations of concern.

Following further evaluation of the COPECs, this assessment was determined to likely overestimate risk to terrestrial and aquatic receptors (including the wetland); therefore, further investigation or assessment of ecological risk from soils and groundwater at IR Site 34 is not recommended.

## **8.0 CONCLUSIONS AND RECOMMENDATIONS**

This RI Report was prepared to (1) collect data to eliminate previously identified data gaps, (2) evaluate the nature and extent of soil and groundwater contamination, (3) evaluate the fate and transport, and (4) assess the risk to human health and the environment at IR Site 34. The following sections present conclusions and recommendations for IR Site 34 based on the evaluation results of the RI.

### **8.1 CONCLUSIONS**

Data collected at IR Site 34 during previous investigations and the RI were found to be sufficient to eliminate previously identified data gaps, describe the nature and extent of soil and groundwater contamination at IR Site 34, and conduct a baseline HHRA and SLERA. The following sections present the conclusions drawn from the evaluations that were conducted during the RI at IR Site 34; those evaluations included the nature and extent of contamination, fate and transport of chemicals, HHRA, and SLERA and risk refinement.

#### **8.1.1 Nature and Extent Conclusions**

The nature and extent evaluation used the physical features of IR Site 34, along with specific details on the hazardous waste generated and past disposal and storage practices associated with these wastes, to identify potential sources of CERCLA chemicals. The following physical features of IR Site 34 were evaluated:

- Former Buildings 330, 331, 343, 344, 472, 474, 475, 476, 477, 479, 510, and 604
- Former ASTs 330A, 330B, 344A, 344B, 344C, 344D, and 331
- Former GAPs 78 and 79
- Former petroleum fuel lines
- Former transformers
- Open space
- Storm sewers AA and BB

Environmental investigations were conducted in these areas (see Section 1.3.4) to identify and assess the extent of CERCLA chemicals in soil and groundwater, and the analytical results were evaluated (see Section 4.0). The results of these investigations are presented separately for soil and groundwater.

### 8.1.1.1 Nature and Extent Soil Results

For the purposes of this RI, contamination is defined as a chemical detected in an environmental sample at IR Site 34 at a concentration exceeding comparison criteria. Metals, VOCs, PAHs, pesticides, PCBs, and TPH were detected at concentrations above comparison criteria in soil samples collected at IR Site 34. Only the following seven chemicals were detected above comparison criteria in more than 10 percent of the samples:

- Metals (arsenic, iron, lead)
- PCBs (Aroclor-1254, Aroclor-1260)
- TPH (as diesel, as motor oil)

Although PAHs were detected above comparison criteria in less than 10 percent of the samples and the evaluation of PAHs relative to B(a)P equivalents showed the site-wide average B(a)P equivalent concentration is below the comparison criteria of 0.62 mg/kg, the site-wide average concentration is influenced by an EPA B(a)P-equivalent value of 8.4 mg/kg and an OEHHA B(a)P-equivalent value of 9.5 mg/kg in a sample of anomalous soil collected above a black clayey sand with a strong diesel odor at location DP16 (north of Building 331).

In addition to exceeding comparison criteria in more than 10 percent of the samples, these seven chemicals, and the following additional chemicals were determined to likely pose potential risk, based on a residential exposure (see the HHRA, Section 6.0)

- PCBs (Aroclor-1248, 1268)
- Pesticides (dieldrin, heptachlor epoxide),
- SVOC (naphthalene)
- VOCs (1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and 1,4-DCB)

After taking into consideration that further evaluation in an FS is based on the risk assessments and reviewing the distribution of concentrations for those chemicals driving risk, residual soil contamination appears to be collocated and limited to six specific areas of concern at IR Site 34 (AOC). The list below (as shown on Figure 4-14) indicates which chemicals are present at each AOC at concentrations potentially posing risk and the likely historical sources of the contaminants.

- **Northwest corner of the site, near the former railroad and former Building 510:** arsenic, PCBs, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to site use and historical sandblasting in former Building 510. Oils and solvents may have been released from sandblasting equipment.

- **North of Building 331:** arsenic, lead, PCBs, naphthalene, and TPH as diesel. Residual contamination in this area appears to be related to use of oils and solvents for woodwork at the former building and metal working at Building 330 to the west.
- **Along the former railroad and south of former Building 331:** lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to site use, historical releases from former AST 331, and use of oils and solvents for woodwork at the former building.
- **Southwest corner of former Building 343 and east of former Building 475:** PCBs. Residual contamination in this area appears to be related to the transformer formerly located in Building 475 and the release of oils from sandblasting equipment.
- **Southeast corner of former Building 343 and northeast corner of former Building 344:** iron, lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to historical releases from former AST 344D, sandblasting of lead-based paints, and lubricants used for sheet metal fabrication. The floor of former Building 343 was rusted, which may have released metals to nearby soil.
- **Southwest corner of the site:** pesticides, PCBs, and VOCs. This area was used between 1995 and 1997 for temporary storage of PCB- and lead-contaminated soil excavated from IR Site 15 (see Section 1.3.3.1). Residual contamination in this area may be related to operation of the TSTA and application of pesticides for weed control.

#### **8.1.1.2 Nature and Extent Groundwater Results**

Arsenic, manganese, iron, 1,2-DCA, 1,2-dichloropropane, chloroform, naphthalene, TCE, vinyl chloride, and PAHs were detected in groundwater samples at concentrations exceeding EPA tap water PRGs. No detected concentrations exceeded ESLs. Diesel- and motor oil-range petroleum hydrocarbons had a greater than 50 percent detection frequency across IR Site 34. The most likely sources of these chemicals are from the disposal of used sandblasting and paint grit; painting activities; chemical storage; sheet metal fabrication; spills near the GAP; leaks from ASTs; and application of chemicals for weed control. However, all of these potential sources were removed after closure of NAS Alameda in 1997. Groundwater contamination at IR Site 34 appears to be confined to several specific areas, as listed below.

- Near the open area in the western-central portion of the site
- Near former Buildings 331, 474, 476, and 604; former GAP 78; the former petroleum fuel pipeline in the southwest corner of the site; and former ASTs 330B, 331, 344A, 344B, and 344D.

These areas have been defined using EPA tap water PRGs, which is unlikely since groundwater beneath IR Site 34 is not a potential drinking water source.

### **8.1.2 Chemical Fate and Transport Conclusions**

The fate and transport evaluation identified the following potential transport mechanisms that may allow the migration of chemicals in soil and groundwater at IR Site 34: direct volatilization, direct transport of soils through erosion by wind and water, and leaching from soils and contaminant migration with flowing groundwater. At IR Site 34 soils and groundwater are affected by a number of chemicals; however, the contaminants are not expected to migrate in a manner that could cause significant exposures to humans or the environment based on future use as a golf course and park.

At IR Site 34, groundwater is affected by most of the chemicals present in site soils, but concentrations are relatively low and do not indicate the presence of a primary source of contamination or the presence of source material. Groundwater contamination, where present, is characterized by diffuse and variable concentrations that do not indicate a primary area of release. Groundwater at IR Site 34 and surrounding sites generally flows from the middle of the Alameda Point peninsula toward the shoreline. Low hydraulic gradients and moderate hydraulic conductivity create relatively slow groundwater flow velocities at IR Site 34. The low-flow velocities of groundwater, low concentrations of chemicals in groundwater, high potential for retardation along the groundwater flow path, and tidal action and surface water flow—which create a mixing zone at the interface with the Oakland Inner Harbor—suggest that chemicals will not discharge to the Oakland Inner Harbor at concentrations of concern.

In addition, IR Site 34 soils are affected by a number of chemicals, most of which exhibit chemical properties that will tend to immobilize them in scattered locations across the site. Primary chemicals that affect groundwater at IR Site 34 include arsenic, manganese, TCE and its degradation products, and TPH. The shallow aquifer at IR Site 34 consists of fine estuarine sand fill, and the low hydraulic gradient and likely (although undocumented) presence of organic carbon in the aquifer are expected to slow migration of these chemicals and inhibit the rate of discharge to the Oakland Inner Harbor. The presence of utility corridors such as the storm sewer west of Building 331 may offer preferential flow pathways that allow more rapid transport of chemicals to the Oakland Inner Harbor.

### **8.1.3 Human Health Risk Assessment Conclusions**

IR Site 34 is currently unoccupied land and so current receptors are not present at the site. The planned reuse of this area is recreational and includes the development of a golf course. IR Site 34 has been identified as a tidelands trust area that is subject to the limitations expressed in the Coastal Zone Management Act, which includes a restriction on residential use. Although planned reuse of IR Site 34 is recreational and future development of the site for residential use is unlikely, the HHRA evaluated a residential scenario to provide alternative risk estimates for unrestricted reuse of the site and to support risk management decisions for the site. The HHRA calculated risks using EPA and DTSC toxicity values assuming both a RME and CTE exposure

scenario. The HHRA also calculated total risks, which include risks from background concentrations of metals, and incremental risks, which exclude risks from background concentrations of metals. The following paragraph summarizes the total risks estimated using EPA toxicity values under a RME scenario.

For future workers and recreational users, cancer risks from groundwater exposure pathways were less than  $1 \times 10^{-6}$  and noncancer HI estimates were less than 1. Potential cancer risks from soil exposure pathways were within the risk management range of  $10^{-4}$  to  $10^{-6}$  for commercial/industrial workers, construction workers, and recreational users. The total HI estimates from soil exposure pathways were greater than 1 for future hypothetical workers and equal to 1 for recreational users. For future residents, potential cancer risks from groundwater exposure pathways were within the risk management range of  $10^{-4}$  to  $10^{-6}$  range for carcinogens and the HI estimates were less than 1. Potential cancer risks from soil exposure pathways exceeded the risk management range of  $10^{-4}$  to  $10^{-6}$  for carcinogens, and the total HI estimates were greater than 1 for future residents.

Many of these risk estimates, however, include risk estimates for a hypothetical residential scenario that is unlikely. In addition, many conservative assumptions were used that may have overestimated the risks. For example, many of the VOCs accounting for most of the risks are based on the maximum detected concentrations in only one soil sample.

#### 8.1.4 Risk Driver Evaluation

The HHRA called a COPC a “risk driver” when the COPC-specific cancer risk exceeded  $1 \times 10^{-6}$  or the COPC-specific HQ exceeded 1. The RI report evaluated each risk driver to determine whether a risk driver should be considered in an FS. As described in Section 6.4, factors considered when including or excluding chemicals for further considerations in FS included background concentrations, frequency of detection, exposure pathways, the B(a)P-equivalent screening level, and sampling methodology (grab samples). The table below lists the risk drivers not recommended for further consideration in an FS.

Risk Drivers not Recommended for Further Consideration in an FS			
	Soil		Groundwater
4-Nitroaniline	B(a)P	Dibenzo(a,h)anthracene	TCE
Aluminum	Benzo(b)fluoranthene	Indeno(1,2,3-cd)pyrene	
Benzo(a)anthracene	Bis(2-ethylhexyl)phthalate	Manganese	

These risk drivers were not recommended for further consideration in an FS for the following reasons (see Appendix H for further details):

- The detection frequency for 4-nitroaniline in soil is low (1 sample out of 35).

- Historical activities and the distribution of aluminum and manganese concentrations exceeding background do not indicate aluminum and manganese are related to Navy activities at IR Site 34.
- The average EPA B(a)P-equivalent concentration (0.47 mg/kg) and OEHHA B(a)P-equivalent concentration (0.52 mg/kg) are below the established screening level of 0.62 mg/kg.
- The potential risk from bis(2-ethylhexyl)phthalate is likely overestimated.
- TCE was only a risk driver for future residents, and, as discussed previously, residential development of IR Site 34 is unlikely. As many of the exposure assumptions used to estimate risks for VOCs were conservative and likely overestimated risks, TCE in groundwater was not recommended for further evaluation.

The table below lists the risk drivers recommended for further consideration in an FS.

<b>Risk Drivers in Soil Recommended for Further Consideration in an FS</b>			
1,2,3-Trichlorobenzene	1,4-DCB	Aroclor-1260	Iron
1,2,4-Trichlorobenzene	Aroclor-1268	Arsenic	Lead
1,2,4-Trimethylbenzene	Aroclor-1248	Dieldrin	Naphthalene
1,2-DCB	Aroclor-1254	Heptachlor epoxide	

Figure 8-1 presents the locations where risk drivers under the residential scenario were detected above risk-based concentrations, and Figure 8-2 presents the locations where risk drivers under the recreational use scenario were detected above risk-based concentrations. Although the RI recommended consideration in an FS for the chemicals listed above, potential risks for these chemicals are based on very conservative assumptions that may have overestimated risks and include risk drivers for hypothetical residential scenarios that are unlikely. For example, 1,2,3-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and iron were only risk drivers under the residential scenario. As discussed previously, residential development of IR Site 34 is unlikely. In addition, potential risks estimated for many of the chemicals listed above may have been overstated. For example, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and 1,4-DCB risk drivers were only detected once and so the estimated risks for these chemicals are not representative of site-wide conditions, but rather represent the potential risks at only one soil sampling location.

### **8.1.5 Screening-Level Ecological Risk Assessment and Risk Refinement Conclusions**

Based on the results of the Step 3a risk refinement, the following chemical was identified as a risk driver in soil at IR Site 34.

- Lead

No risk drivers were identified in groundwater at Site 34.

Although lead may contribute to ecological risk at IR Site 34, based on the SLERA, a baseline ERA is not recommended because the SLERA likely overestimated risk, there is a lack of current suitable habitat, and future land use would not generate much ideal habitat for wildlife. IR Site 34 currently consists of predominantly Intensively Developed area and two potential wetland areas. Intensively Developed areas have little vegetation and typical urban wildlife, such as California ground squirrel, scrub jays, and American robins, may be observed in these areas but to a lesser extent than in the landscaped/developed areas, because less foraging habitat is available in these areas. The potential wetland areas provide minimal habitat to support plant and invertebrate populations and do not provide suitable habitat for small mammals. In addition, because of high marine vessel activity in the Oakland Inner Harbor it is unlikely that this area will be used by nesting birds.

Site-related chemicals in soil and groundwater at IR Site 34 are not expected to affect the potential wetland areas or the Oakland Inner Harbor for the following reasons. It is unlikely that groundwater or surface water runoff from IR Site 34 would affect the potential seasonal wetland located within the southwest corner of the site because the site topography would prevent it from reaching this potential wetland. Although surface water generally flows towards the wetland located to the north of the site, precipitation typically evaporates into the atmosphere, infiltrates to groundwater, or runs off into the storm drain system. The potential wetland is also not likely to be affected by site-related chemicals in groundwater because it lies between a series of parallel rock riprap walls that together form a terrace of land that is the shoreline and is tidally inundated at such a frequency as to not present suitable habitat for small mammals, dilution would occur as groundwater mixes with surface water (Oakland Inner Harbor), and groundwater COPECs were identified based on the assumption that no dilution, retardation, or degradation will occur between the location where the groundwater risk drivers were detected and the Oakland Inner Harbor/wetland. In addition, the low-flow velocities of groundwater, low concentrations of VOCs in groundwater, high potential for retardation along the groundwater flow path, and tidal action and surface water flow that create a mixing zone at the interface with the Oakland Inner Harbor suggest that chemicals will not discharge to the Oakland Inner Harbor at concentrations of concern.

Following further evaluation of the COPECs, this assessment was determined to likely overestimate risk to terrestrial and aquatic receptors (including the wetland); therefore, further investigation or assessment of ecological risk from soils and groundwater at IR Site 34 is not recommended.

## **8.2 RECOMMENDATIONS**

Based on the conclusions of the evaluations discussed above, additional site characterization of soil or groundwater is unnecessary at IR Site 34 to complete the RI. The nature and extent of

soil and groundwater contamination has been adequately characterized and the data were found to be sufficient to conduct an HHRA and SLERA.

The Navy recommends the chemicals listed below and the five AOCs where contamination appears to be limited to be further considered in an FS (see Figure 8-3). No action is recommended for groundwater or the AOC located in the southwest corner of former Building 343 and east of former Building 475. Although PCBs were detected in samples collected within this area at concentrations greater than the residential PRGs, this area is not specifically identified for further evaluation in an FS because of the relatively low risk of PCBs based on the HHRA.

- **Northwest corner of the site, near the former railroad and former Building 510:** arsenic, PCBs, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to site use and historical sandblasting in former Building 510. Oils and solvents may have been released from sandblasting equipment.
- **North of Building 331:** arsenic, lead, PCBs, and naphthalene. Residual contamination in this area appears to be related to use of oils and solvents for woodwork at the former building.
- **Along the former railroad and south of former Building 331:** lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to site use, historical releases from former AST 331, and use of oils and solvents for woodwork at the former building.
- **Southeast corner of former Building 343 and northeast corner of former Building 344:** iron, lead, and TPH as diesel and motor oil. Residual contamination in this area appears to be related to historical releases from former AST 344D, sandblasting of lead-based paints, and lubricants used for sheet metal fabrication. The floor of former Building 343 was rusted, which may have released metals to nearby soil.
- **Southwest corner of the site:** pesticides, PCBs, and VOCs (1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-DCB, and 1,4-DCB). This area was used between 1995 and 1997 for temporary storage of PCB- and lead-contaminated soil excavated from IR Site 15 (see Section 1.3.3.1). Residual contamination in this area may be related to operation of the TSTA and application of pesticides for weed control.

The Navy recommends an FS be prepared to evaluate options to address contamination at IR Site 34 potentially posing a risk to human health. The FS should consider the future land use in evaluating these options. In addition, the Navy recommends the following additional sampling for inclusion in the FS:

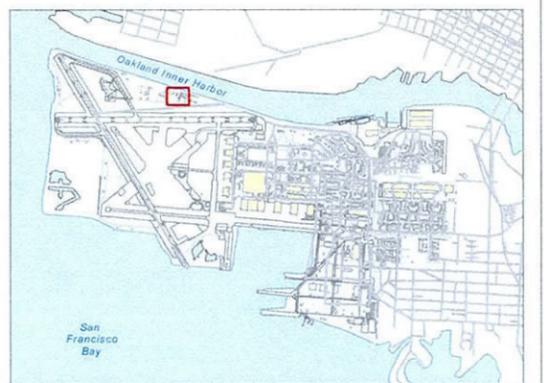

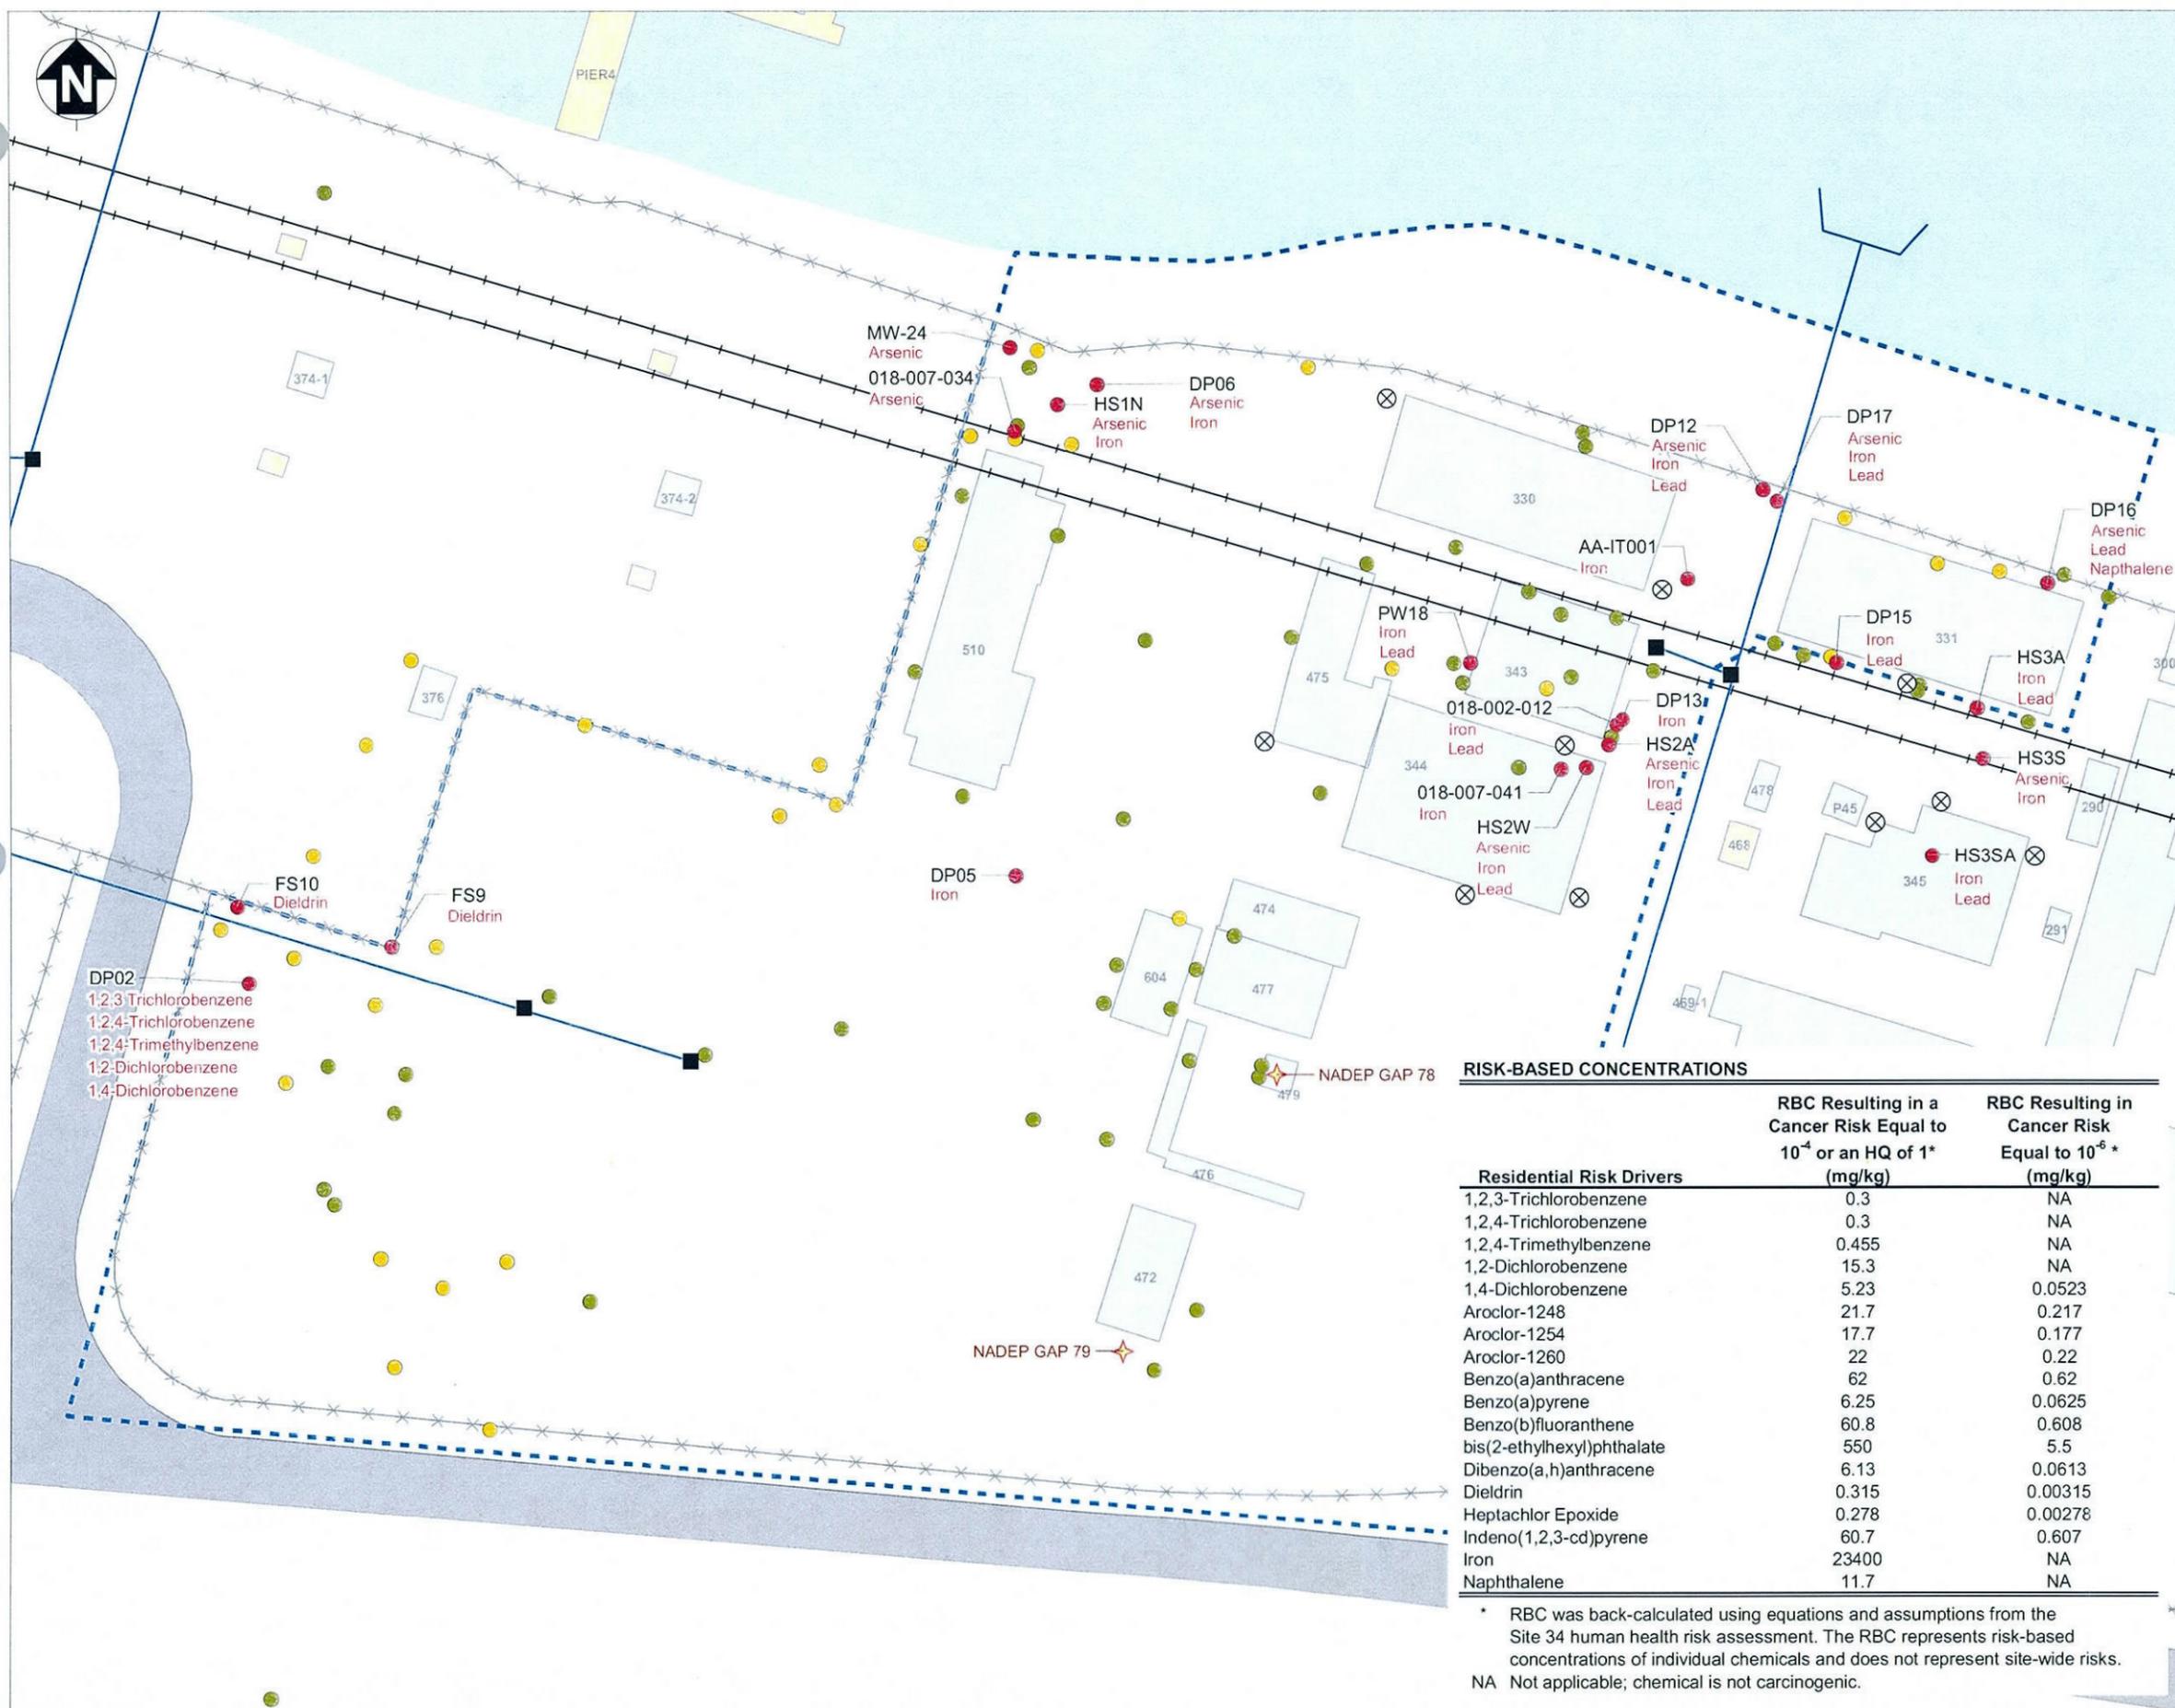

- Sampling within the vicinity of DP02 to verify previous VOC results

- Sampling of soil and groundwater for fuel-related contamination north of Building 331 and near sampling location DP16, where a layer of black sand with a strong diesel odor was identified

Additionally, concentrations of TPH were detected above the comparison criteria, and low-level concentrations of TPH were detected across IR Site 34. Although TPH is not a contaminant under CERCLA it was addressed in the nature and extent evaluation because fuels and lubricants were used at various locations across the site and an objective of this RI was to meet TPH closure requirements. At Site 34, TPH-affected soil (mostly diesel and motor oil) appears to be located at isolated locations near former ASTs and buildings where lubricants were used. Based on the current data, TPH in soil is collocated with CERCLA chemicals in soil and will be addressed with the CERCLA chemicals identified above in the FS. Further consideration of TPH-affected soil in the TPH program is not recommended.

## **A1.0 INTRODUCTION**

This appendix describes field activities performed prior to and as part of the remedial investigation (RI) of Installation Restoration (IR) Site 34, Alameda Point. The following sections summarize field methodology, quality control (QC), and any deviations from the work plan during the following investigations at IR Site 34: the Phase I environmental baseline survey (EBS) (Environmental Management Resources West, Inc. 1994), Phase 2a and 2b EBS (International Technology Corporation [IT Corp.] 2001), fuel pipeline removal action (IT 1999), site inspection (Bechtel Environmental, Inc. 2003), and remedial investigation (RI) sampling events (SulTech 2006).

## **A2.0 FIELD METHODOLOGY**

The section describes the methods used in the field activities related to installation of soil borings and monitoring wells, collection of soil and groundwater samples, and removal of fuel pipelines.

### **A2.1 UNDERGROUND UTILITY LOCATION AND CLEARANCE**

Prior to the start of field work, an underground utility survey and clearance was conducted to locate subsurface utilities within IR Site 34. The utility clearance was intended to locate any existing underground utilities, including water distribution piping, telecommunications lines, storm sewer lines, sanitary sewer lines, fire water lines, and electrical lines. The utility survey was conducted at IR Site 34 by a local, private utility locating company. Colored spray paint was used to mark the locations and types of utilities encountered.

In addition to the private utility locator, Underground Service Alert was notified 48 hours prior to drilling or removal activities.

### **A2.2 INSTALLATION OF SOIL BORINGS AND COLLECTION OF SOIL SAMPLES**

Soil samples were collected during various investigations at IR Site 34. Depending on the type of investigation, soil borings may have been completed using a hollow-stem auger with a split-spoon sampler, direct-push drilling, hand-auger, or slide hammer. In addition, some samples were field screened using x-ray fluorescence (XRF) technology to help identify appropriate soil sampling locations. Each method is discussed below.

#### **A2.2.1 Hollow-Stem Auger**

Soil borings were drilled with a truck-mounted, hollow-stem auger drill rig using an 8.25-inch outer diameter auger. Soil samples were collected by using a drop hammer to drive a split-spoon sampler into the ground. The split-spoon sampler was opened, and the soil was screened in the field using a photoionization detector (PID). Selection of soil samples for analysis was at a pre-determined depth above the water table; typically, two samples were collected from each

boring: one surface sample (0 to 2 feet below ground surface [bgs]) and a deeper sample just above the water table. Soil samples selected for analysis were placed in clean 8-ounce clear glass jars. Soil samples to be analyzed for volatile organic compounds (VOC) were collected directly from the split-spoon sampler using an EnCore<sup>®</sup> sampling device, which cored a 5-gram sample from the split-spoon sampler. The soil sample containers were labeled with unique sample identification numbers and placed in chilled coolers awaiting laboratory delivery. Chain-of-custody documents accompanied the samples to the laboratory.

Monitoring wells 34-MW20 through 34-MW24, MW07B, and MW07C were drilled using this soil boring method (see Figure A-1). The construction of these monitoring wells is described in Section A2.3.1 of this appendix. Copies of the soil boring logs and well construction diagrams are included in Appendix B of the RI Report.

### **A2.2.2 Direct-Push Drilling**

Soil borings DP05 through DP08, DP10, DP12, DP13, and DP15 through DP19 were drilled using direct-push drilling equipment consisting of a hydraulic drive-point system operated from the rear of a modified flat-bed pickup truck. Continuous soil samples were collected using a hydraulic hammer to advance a 4-foot-long, 1.5-inch-diameter, hollow core stainless steel sampler lined with a disposable acetate tube into the ground. Upon retrieval of the soil core, the inner acetate tube was pushed out of the sampler and a California state-registered geologist measured the percent recovery and logged the core in accordance with the Unified Soil Classification System.

Soil sampling depths and suites of analyses differed depending on the phase of sampling. Once the soil sample interval was collected, the acetate tube section containing the sample was cut and capped with Teflon<sup>®</sup> sheets and a plastic end cap, or the soil was placed into clean 8-ounce glass jars. For samples requiring analysis of VOCs and total petroleum hydrocarbons (TPH) as gasoline, an Encore<sup>®</sup> sampler was used to extract the sample from the deepest end of the interval before capping. The soil sample containers were labeled with unique sample identification numbers and placed in chilled coolers awaiting laboratory delivery. Chain-of-custody documents accompanied the samples to the laboratory.

The borings were backfilled with grout consisting of 5 percent bentonite-cement slurry the same day of drilling. The slurry was poured into the boring, and after settling, the boring was topped off with additional slurry to the surface grade.

### **A2.2.3 Shallow Soil and Sediment Sampling**

Small disposable scoops, shovels, steel spades, a hand auger, or a slide hammer were used to collect surface soil samples and deeper soil samples not exceeding 5 feet bgs. Samples collected from deeper than 2 feet bgs could not be reached by hand from the surface and were collected indirectly with a shovel. Disposable scoops were then used to collect soil that did not come into direct contact with the shovel. When using a stainless steel spade, the spade was used to

penetrate the top 2 inches of soil within a 6 inch by 19 inch rectangular template to collect the needed surface soil sample volume need for analysis. Soil samples from hand-auger borings were collected by advancing a hand auger to the desired depth and then extracting the soil sample from the boring.

Soil sampling depths and suites of analyses differed depending on the phase of sampling. Soil chosen for analysis was placed into clean, 8-ounce glass jars directly from the disposable scope, stainless steel spade, or hand auger. For samples collected before 2001 and requiring analysis of VOCs and TPH as gasoline, a slide hammer was used to drive brass sleeves into the undisturbed soil at the desired sampling depth. The brass sleeves were capped with Teflon<sup>®</sup> sheets and plastic end caps. Encore<sup>®</sup> samplers were used during more recent investigations to collect samples for analysis of VOCs and TPH as gasoline. The soil sample containers were labeled with unique sample identification numbers and placed in chilled coolers awaiting laboratory delivery. Chain-of-custody documents accompanied the samples to the laboratory. All shallow soil borings were backfilled with cuttings.

Shallow soil sampling methods were used to collect soil samples from the following locations: 004-001-001, 004-001-002, 004-001-003, 004-001-004, 004-003-008, 004-003-009, 004-Z03-005 through 004-Z03-007, 018-001-001, 018-001-002, 018-001-005 through 018-001-008, 018-002-003, 018-002-004, 018-002-009 through 018-002-012, 018-003-013 through 018-003-019, 018-004-020 through 018-004-023, 018-005-024, 018-005-025, 018-006-026, 018-Z03-027 through 018-Z03-030, 018-007-033 through 018-007-041, and 018-Z03-031 through 018-Z03-032 (see Figure A-1).

Sediment samples were collected from storm sewer manholes and catchment basins using plastic disposable scoops. If the sediment sample was not within reach, a clamshell grab sampler mounted on an extendable handle was used to collect the sediment sample. The sediment sample was placed into 8-ounce glass jars directly from the disposable scoop or clamshell sampler. The sediment sample containers were labeled with unique sample identification numbers and placed in chilled coolers awaiting laboratory delivery. Chain-of-custody documents accompanied the samples to the laboratory. One sediment sample was collected within IR Site 34 at location AA-IT001 (see Figure A-1).

#### **A2.2.4 X-Ray Fluorescence Sampling**

XRF technology was used to assist with identifying soil sampling locations by field screening samples for specific heavy metals. The XRF device was calibrated in the field daily using National Institute of Standards and Technology standards for chromium and lead. Surface soil samples (0 to 3 inches bgs) were collected using a clean stainless steel trowel and placed in clean zip-lock bags, and analyzed in the field for lead and chromium using the XRF device. If field analysis results showed concentrations of chromium or lead above screening criteria, then a deeper soil sample was collected from that same location. In such a case, a subsurface soil sample was collected every 1 foot (from 12 to 15 inches and 24 to 27 inches bgs) in depth with a clean, stainless steel hand-auger and placed in a zip-lock bag for XRF analysis. In addition, soil samples from each location and depth were also placed into 4-ounce glass jars, and 20 percent of

these samples were sent to an off-site laboratory for confirmatory analysis. The soil sample containers were labeled with unique sample identification numbers and placed in chilled coolers awaiting laboratory delivery. Chain-of-custody documents accompanied the samples to the laboratory.

XRF field screening occurred at the following locations: HS-1A, HS-1W, HS-1E, HS-1N, HS-2A, HS-2N, HS-2S, HS-2W, HS-3A, HS-3E, HS-3S, HS-3W, HS-4E, HS-4W, HS-5E, HS-5S, HS-5W, HS-6A, HS-6N, HS-6S, HS-6W, HS-7N, HS-7S, HS-7W, PW1 through PW18, PW 3A, PW4A, PW7A, PW7C, PW8A, PW9-10-15A, PW9-6A, and PW11A (see Figure A-1).

Samples for confirmatory analysis were collected from the following locations: HS-1A, HS-1E, HS-1N, HS-1W, HS-2A, HS-2W, HS-3A, HS-3E, HS-3SS, HS-3SA, HS-6N, HS-6S-5W, PW1, PW4, PW4A, PW7, PW8, PW10, PW14, PW17, PW18, PW9-10-15A, and PW9-6A (see Figure A-1).

### **A2.3           INSTALLATION OF MONITORING WELLS AND COLLECTION OF GROUNDWATER SAMPLES**

This section describes installation of permanent and temporary monitoring wells and collection of groundwater samples at IR Site 34. Appendix B of this RI Report contains available well construction diagrams and monitoring well sampling sheets.

#### **A2.3.1           Permanent Monitoring Well Installation**

Hollow-stem auger drilling equipment was used to advance a boring for monitoring wells 34-MW20 through 34-MW24, MW7B, and MW7C, as described in Section A2.2.1. Table A-1 presents the construction details for these monitoring wells.

The monitoring wells, except for MW7B and MW7C, were purged using low-flow-rate purging and bladder pumps until water quality parameters stabilized. Monitoring wells MW7B and MW7C were discovered during the RI field investigation; therefore, well construction information was not available. These two wells were not purged, and the groundwater samples were collected with a peristaltic pump. The water samples were collected in appropriate sample containers depending on analysis. The groundwater sample containers were labeled with unique sample identification numbers and placed in chilled coolers awaiting laboratory delivery. Chain-of-custody documents accompanied the samples to the laboratory.

#### **A2.3.2           Temporary Monitoring Well Installation**

Temporary groundwater monitoring wells were installed to depths ranging from 4 to 65 feet bgs at the following 29 locations: 004-003-008, 004-003-009, 018-007-033, 018-007-035, 018-007-036, 018-007-039, 018-007-041, 030-FLI-519, 473-002, and DP01 through DP19 (see Figure A-1). Temporary monitoring wells were constructed by inserting a 5-foot section of a 1-inch diameter polyvinyl chloride (PVC)-slotted well screen (0.01-inch slot size) fitted with

an end cap into the soil boring. The upper sections of the wells were solid PVC pipes. The temporary wells were destroyed by removing the well material and backfilling the boring with a cement and bentonite mixture.

Groundwater samples were collected from the temporary monitoring wells using a disposable bailer or a low-flow-rate peristaltic pump. The water samples were collected in appropriate sample containers depending on analysis. The groundwater sample containers were labeled with unique sample identification numbers and placed in chilled coolers awaiting laboratory delivery. Chain-of-custody documents accompanied the samples to the laboratory.

### **A2.3.3 Aquifer Test**

Aquifer tests were conducted at shallow and deep monitoring wells (34-MW20 and 34-MW24, respectively) at IR Site 34. The aquifer tests consisted of a slug withdrawal test or "rising head" tests. The slug test involved insertion (slug in) or withdrawal (slug out) of a solid cylinder into or from a well and monitoring the resulting change in water level over time.

A pressure transducer (In-Situ Inc.'s Hermit 3000 or Mini Troll Pro) was lowered into the monitoring wells to conduct the slug test. The transducer was set to collect water level readings at shorter time increments at the beginning of the test, when recovery is quick, to longer increments of time toward the end of the test, when recovery is slower. A solid slug of known volume was then instantaneously inserted (or removed), and water level readings were automatically recorded during water level recovery. The tests in each well ran for approximately 25 to 50 minutes. The slug test data were used to estimate the hydraulic properties of materials beneath the site. Appendix C of this RI Report presents the results of the slug tests.

## **A2.4 FUEL PIPELINE REMOVAL**

This section describes the fuel pipeline location and pavement removal, and the field activities associated with fuel pipeline removal and site restoration.

### **A2.4.1 Fuel Pipeline Location and Pavement Removal**

Fuel pipelines were located using radio frequency direct coupling and induction testing. The outline of the fuel pipelines and any utilities were marked with paint. If asphalt or concrete covered the fuel pipeline, it was saw cut, removed, and stockpiled on-site awaiting off-site disposal. Typically, the width of the removed asphalt or concrete was 60 inches; however, additional concrete was removed if adjacent pipelines were located several feet apart or where soil contamination required overexcavation of the fuel pipeline trench (IT Corp. 1999).

#### **A2.4.2 Fuel Pipeline Removal**

Residual product within the fuel pipelines was removed through existing valves and fitting when possible. Low points in the fuel pipelines were identified from as-built drawings and uncovered. The fuel pipelines were tapped using tapping saddles and a sealed, non-sparking, air-driven hot tapping drill to inspect line and contain any product using a vacuum truck (IT Corp. 1999).

Fuel pipeline removal involved using a backhoe to initially expose the tops of the fuel pipelines, where possible. The fuel pipelines were further exposed by hand-digging. If product was discovered during pipeline removal, the excavation trench was lined with plastic sheeting and one end of the pipe segment would be raised so that any product could drain toward the vacuum truck at the other end of the pipe. After draining, the end near the vacuum truck was capped with absorbent pads and plastic sheeting to capture any residual product.

A PID was used to monitor the petroleum hydrocarbon vapor inside the fuel pipeline. If petroleum hydrocarbon vapors were detected in quantities above 100 parts per million, additional holes were drilled in the top of the pipeline to increase ventilation. Combustible gases also were monitored inside the pipeline. When combustible gases were below 10 percent of the calibrated lower explosive limit, the pipe was deemed ready for removal (IT Corp. 1999). After the fuel pipeline was determined to be free of product, petroleum hydrocarbon vapors, and combustible gas, a backhoe was used to remove the pipe by pinching the steel pipeline until the metal failed and split apart. The pipeline sections were placed in a storage bin for transportation and off-site disposal.

During removal of the fuel pipelines, soil samples were collected from the bottom of the excavations; only one sample (030-FLI-122) was collected within the boundaries of IR Site 34 (see Figure A-1). Prior to collecting the soil sample, any soil that fell into the excavation from the surface or sidewalls was removed from the bottom of the excavations with a shovel, exposing the relatively undisturbed material beneath. Soil samples were collected directly from the backhoe bucket with small, disposable plastic scoops. Soil samples that were to be analyzed for VOCs and TPH as gasoline were collected directly from the backhoe bucket using brass sleeves. One groundwater sample (030-FLI-519) was collected from the excavation trench (see Figure A-1). The soil sample containers were labeled with unique sample identification numbers and placed in chilled coolers. Chain-of-custody documents accompanied the samples to the laboratory.

#### **A2.4.3 Fuel Pipeline Site Restoration**

Site restoration after the fuel pipeline removal and abandonment included backfilling excavation trenches, compacting the soil, and replacing the asphalt or concrete. Backfill was placed in the trenches in 8-inch to 12-inch lifts and compacted. Compaction tests were randomly conducted on the completed lifts (IT Corp. 1999). After backfilling, the surface of the trench areas was resurfaced to natural conditions by reestablishing roadways with asphalt pavement, lawns, or open areas with topsoil and grass seed, and sidewalks with concrete.

## **A2.5 SURVEY**

The locations of all new monitoring wells were surveyed to an accuracy of plus or minus 0.1 foot horizontally and plus or minus 0.01 foot vertically. Horizontal coordinates are reported in accordance with the California State Planar Coordinate System, and vertical coordinates were reported as feet above Alameda Point mean lowest low water level.

## **A2.6 DECONTAMINATION AND MANAGEMENT OF INVESTIGATION-DERIVED WASTE**

This section describes procedures for decontamination of sampling equipment and management of investigation-derived waste (IDW).

### **A2.6.1 Decontamination Sampling Equipment**

Decontamination procedures used during collection of soil samples included steam-cleaning augers, rods, bits, the back end of the drill rig, split-spoon sampler, and core barrel sampling device both before work began and between activities at different boring locations. The hand-auger, slide hammer, and stainless steel trowels and shovels were cleaned with a brush before work began and between activities at different boring locations.

Groundwater samples were collected from temporary monitoring wells using disposable bailers or a peristaltic pump with disposable tubing; therefore, decontamination was not necessary. However, groundwater samples were collected from permanent monitoring wells using a reusable bladder pumps and electric sounders were used to measure water levels. The bladder pumps and electric sounder were decontaminated before and after use at each permanent monitoring well. Decontamination was performed by rinsing the reusable equipment with deionized water, washing with a trisodium phosphate detergent, rinsing with deionized water, and wiping the reusable equipment before reuse.

### **A2.6.2 Management of Investigation-Derived Waste**

IDW generated during field activities included soil cuttings from borings and monitoring wells, contaminated soil excavated during removal of pipelines, groundwater from monitoring well purging, wastewater from decontamination procedures, and product from inactive fuel pipelines. Soil cuttings, groundwater, and wastewater were containerized in 55-gallon drums or roll-off bins and then transported to a temporary storage area at Alameda Point. Free product removed from the fuel pipelines was transferred to temporary on-site storage tanks. Composite samples were collected from the IDW to characterize the waste for disposal off site at an appropriate waste facility.

## **A3.0 QUALITY CONTROL**

In general, QC samples collected during field activities included field duplicates for groundwater, equipment rinsate samples, and trip blanks. The following sections discuss the field QC samples and laboratory QC samples. The use of field duplicates for soils and laboratory QC also is discussed in this section.

### **A3.1 EQUIPMENT RINSATE SAMPLES**

Equipment rinsate samples demonstrate whether decontamination procedures are effective in removing chemicals from the field sampling equipment. The presence of contamination in equipment rinsate samples indicates that cleaning procedures were not effective, allowing for the possibility of cross-contamination. Equipment rinsate samples were collected once per sampling event.

### **A3.2 MATRIX SPIKE AND MATRIX SPIKE DUPLICATES**

Matrix spike (MS) and MS duplicate (MSD) samples are aliquots of a sample spiked in the analytical laboratory with known quantities of target compounds, and analyzed using the same procedures as for field samples. The MS recovery provides information about the accuracy of the analysis process, whereas the relative percent difference (RPD) of the MS/MSD recoveries is used to assess matrix-specific precision. Typically, additional sample volume is collected for 1 sample in every batch of 20 samples.

### **A3.3 FIELD DUPLICATES**

Field duplicate pairs consist of two samples of the same matrix (an original and a duplicate) collected at the same time and location (to the extent possible), using the same sampling techniques. Field duplicate samples are collected at the same time and from the same source as environmental samples and then submitted as separate samples to the laboratory for analysis.

Combined field and laboratory precision are evaluated by collecting and analyzing field duplicates and then calculating the variance between the samples, as follows:

$$RPD = \frac{|A-B|}{(A+B)/2} \times 100$$

where

- A = First duplicate concentration
- B = Second duplicate concentration

Groundwater field duplicate samples were collected at a frequency of 10 percent and were analyzed for the same chemicals as their corresponding original samples. Duplicate samples were not collected for waste samples.

#### **A3.4 TRIP BLANKS**

Trip blanks were prepared in the laboratory by pouring carbon-free (or distilled) water into the appropriate sample containers and including all appropriate preservative chemicals. The trip blank then traveled with the cooler and other sample containers from the laboratory to the field and back to the laboratory. The purpose of the trip blank sample is to monitor for introduced contamination of VOCs and TPH as gasoline between the field and the laboratory.

#### **A3.5 SOURCE WATER BLANK SAMPLES**

Source water blanks were collected during each sampling event. Source blanks consisted of the deionized water used for equipment decontamination and for the collection of equipment rinsates. The purpose of the source blank sample is to monitor the source of water used during field activities.

#### **A3.6 INSTRUMENT CALIBRATION AND FREQUENCY**

All field equipment was operated, maintained, calibrated, and standardized in accordance with U.S. Environmental Protection Agency's (EPA) and manufacturer's recommended procedures. The equipment was calibrated at the beginning of each day and checked throughout the day as warranted. Laboratory instrument and equipment testing, inspection, and maintenance followed the EPA Contract Laboratory Program Statement of Work for Organic Analysis (EPA 1999).

#### **A3.7 LABORATORY DATA VALIDATION**

A data validation review was completed for the soil and groundwater sampling events. Appendix F to this RI Report presents the QC summary report for these sampling events. Of the data collected at IR Site 34, all but 0.1 percent were considered usable and data quality was within acceptable limits.

#### **A4.0 DEVIATIONS FROM THE WORK PLAN/SAMPLING AND ANALYSIS PLAN**

Table A-2 lists the deviations from the work plan and sampling and analysis plan. The deviations did not impact the investigation.

**TABLE A-2: SUMMARY OF DEVIATIONS FROM THE WORK PLAN AND SAMPLING AND ANALYSIS PLAN**  
 Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Original Work Statement	Deviation	Media	Work Plan/SAP Section	Reason for Deviation	Benefit of Deviation	Sampling Locations Affected	Effect on Data
None	Existing monitoring wells (MW7B and MW7C) were found at IR Site 34 during the field investigation. A purge line was placed approximately 3 feet below the groundwater surface at the existing monitoring wells. Samples were collected with a peristaltic pump. The field team did not purge the well or collect water quality parameters.	Groundwater	NA	To qualitatively assess water quality in unknown historic monitoring wells.	A field team was already present at the site and had the appropriate equipment on hand. However, the field team did not have well construction details, thus they could not properly purge the well so water quality results should be considered qualitative and not quantitative. Data obtained from these monitoring wells will help with the qualitative assessment of deeper aquifers at the site.	Addition of two groundwater monitoring well locations.	Additional data for site characterization were obtained. However, the analytical results are qualitative because proper purging could not be performed.
Step-out criteria for XRF samples was to collect four samples in a semicircle around each planned sampling location with previous chemical concentrations exceeding screening criteria.	Step-out locations were adjusted to provide more spatial coverage and eliminate redundant sampling locations.	Soil	Section 5.1, pages 25-28	The sampling plan was based on a conceptual site model where the investigation would define discrete metals hot spots. The number of planned sampling locations showed that discrete hot spots were not present and metals exceeded screening criteria in a widespread fashion.	Provided a more cost-effective method for screening site-wide metals concentrations without compromising data quality. More widespread presence of metals in soil did not require such localized delineation but a more general delineation that was provided by the amended plan.	Approximately 16	The quality of the XRF data was not compromised. The intent of the XRF investigation was to define the extent of chromium and lead at concentrations exceeding screening criteria. By altering the step-out sampling plan, a greater portion of the site could be characterized at a lower but more appropriate level of detail.
Borings will be continuously logged to assist in developing a geologic profile.	Many of the hand augered soil samples were not logged in the field because of time constraints. Boring logs were recreated from excess sample volume several weeks later and from adjacent sample descriptions.	Soil	Section 5.1, Page 26	Time constraints during field work.	None. However, data quality was not substantially compromised.	All subsurface hand augered soil samples.	All of the boring logs were recreated after the field event based on excess sample volume and field notes. Distinct interfaces in the soil were not recorded. However, the general soil descriptions were not compromised.
Groundwater samples will be collected from each direct push boring location. These groundwater samples will be analyzed for VOCs, TPH-purgable, TPH-extractable, SVOCs, PAHs, PCBs, pesticides, and metals.	At direct push location DP19 the groundwater sample was not analyzed for PAHs or PCBs.	Groundwater	Section 2.1.1, Page 30	Groundwater recharge at this location was very slow, resulting in insufficient sample volume being collected from this sample location.	None.	One location, DP19.	Data quality was not substantially compromised since PAH constituents are reported under SVOC analysis and PCBs were not detected above detection limits at IR Site 34.

Notes:

SulTech. 2006. "Final Remedial Investigation Work Plan, Installation Restoration Site 34, Alameda Point, Alameda, California." January.

IR	Installation Restoration	VOCs	Volatile organic compounds
NA	Not applicable	XRF	X-ray fluorescence
PAHs	Polycyclic aromatic hydrocarbons		
PCBs	Polychlorinated biphenyls		
SVOCs	Semivolatile organic compounds		
SAP	Sampling and analysis plan		
TPH	Total petroleum hydrocarbons

## C1.0 INTRODUCTION

On behalf of the Navy, SulTech conducted slug tests in two monitoring wells at Installation Restoration (IR) Site 34 at Alameda Point, Alameda, California. The slug tests were used to estimate the hydraulic properties of materials beneath the site. This appendix summarizes the methods used to conduct and interpret the slug tests (Section C2.0), presents the estimated hydraulic parameters for IR Site 34 (Section C3.0), and presents the conclusions based on the slug test results (Section C4.0).

## C2.0 METHODS

The slug tests were performed at two monitoring wells (34-MW20 and 34-MW24) on July 7, 2006, and March 1, 2007; these wells are shown on Figure C-1. The slug tests were performed in accordance with the U.S. Environmental Protection Agency (EPA) Standard Operating Procedure No. 2046, dated October 3, 1994 (EPA 1994).

To avoid damaging the field transducer, the senior hydrogeologist in the field recommended that slug withdrawal tests only be conducted in well 34-MW20; three tests were performed. Two slug injection tests and two slug withdrawal tests were conducted in well 34-MW24. Background water level readings were taken in well 34-MW24 to evaluate whether conditions are likely to change during a slug test in response to barometric pressure or tides. However, the data collected during this background test were not useable because the transducer malfunctioned presenting little or no change in barometric pressure even though water level readings showed that on average 3 feet of water was displaced. However, the transducer did function as required during all of the other slug tests.

The slug test involves insertion (slug in) or withdrawal (slug out) of a solid cylinder into or from a well and monitoring the resulting change in water level over time. The slug used in the tests was made of polyvinyl chloride pipe, with end caps and filled with sand for weight. The slug dimensions were somewhat different for each well to accommodate for well diameter and transducer cable thickness. The slugs for 2-inch wells 34-MW20 and 34-MW24 were 60 inches long, with a diameter of 0.75 and 1.5 inches (respectively), and weighed approximately 5.65 and 5.5 pounds. The theoretical displacement of water levels as a result of slug insertion or withdrawal inside the 2-inch wells 34-MW20 and 34-MW24 was estimated at 1.7 and 3 feet, respectively.

The depth to water (static water level) was measured before the tests in each well. Next, the pressure transducer (In-Situ Inc.'s Hermit 3000 or Mini Troll Pro) was set approximately 0.5 to 2 feet above the bottom of the well. The transducer was set to collect water level readings at shorter time increments at the beginning of the test, when recovery is quick, to longer increments of time toward the end of the test, when recovery is slower. The slug was then instantaneously inserted (or removed), and water level readings were automatically recorded during water level recovery. The tests in each well ran for approximately 25 to 50 minutes.

The slug test data were used to calculate the horizontal hydraulic conductivity of the fine sand fill materials in which well 34-MW20 is screened and fine sand and clay materials in which well 34-MW24 is screened. The boring logs for each well are presented in Attachment C-1. Review of the boring logs indicated well 34-MW20 is screened in a shallow unconfined unit, while well 34-MW24 is screened beneath the Bay Mud unit in a confined aquifer.

Hydraulic conductivity is a measure of the capacity of a porous medium to transmit water. It is defined as the volume of water that will move in a unit time under a unit hydraulic gradient through a unit area measured at right angles to the direction of flow. The dimensions of hydraulic conductivity are length per time or velocity. Hydraulic conductivity is governed by the size and the shape of the pores, the effectiveness of the interconnection between pores, the roughness of mineral particles, the degree of soil saturation, and the physical properties of the fluid.

For the confined aquifer represented by well 34-MW24, a determination of the storage coefficient (S) was also possible. The S of an aquifer represents a volume released from an aquifer per 1 foot surface area per 1 foot change in head. The coefficient's value characterizes the ability of an aquifer to store water. Mathematically, the S value is dimensionless (volume of water divided by a product of surface area and head change). The S value depends on whether the aquifer is confined or unconfined. In a confined aquifer setting, the load on top of an aquifer is supported by the solid rock skeleton and the hydraulic pressure exerted by water (the hydraulic pressure acts as a support mechanism). Water derived from storage of a confined aquifer results from (1) the expansion of water as the aquifer is depressurized (pumped) and (2) compression of the aquifer. Because of these variables, the S value of most confined aquifers ranges from 0.00001 to 0.001. Conversely, in an unconfined aquifer setting, the predominant source of water is from gravity drainage and the expansion of water and compaction of the rock skeleton is negligible. Thus, the S value is approximately equal to a value of specific yield and ranges from 0.1 to about 0.3.

Based on review of the boring logs, well 34-MW20 was interpreted to fully penetrate the sand fill materials, while well 34-MW24 partially penetrates the fine sand unit. The Bouwer and Rice method (Bouwer and Rice 1976) for a slug test in an unconfined aquifer was used to interpret slug test data from the shallow well 34-MW20. For the deep well 34-MW24, which better represents confined aquifer conditions, the following two methods for a slug test in a confined aquifer were used: Bouwer and Rice (1976) and Cooper, Bredehoeft, and Papadopulos (1967). The analysis was performed using computer program AQTESOLV Pro 3.0 (Hydrosolve, Inc. 2000), which uses a suite of analytical solutions to assess aquifer properties from pumping tests and slug tests. The Bouwer and Rice method allows for calculation of hydraulic conductivities. In addition, the Cooper, Bredehoeft, Papadopulos method allows for calculation of the aquifer S value (Hydrosolve, Inc. 2000).

Before evaluating the hydraulic parameters, data from pressure transducers were graphed to evaluate its suitability for analysis. The graphs indicated that water level data for both wells are suitable for analysis. Prior to importing the water level data from transducers into the AQTESOLV, the data were normalized by shifting a peak response (or trough for slug out) for

the displacement to mark the beginning of the test (time zero). The water level prior to insertion (or extraction for slug out) of the slug was used as the initial level for calculation of the initial displacement.

When analyzing the water level displacement-over-time data in the AQTESOLV, the matching of the straight-line or curvilinear solutions to displacement-time data was done first using the automatic feature in the program. If deemed necessary, the initial estimate of hydraulic conductivity was then adjusted using visual matching of solution to displacement-time data.

### **C3.0 RESULTS**

This section discusses the estimated hydraulic parameters for the unconfined unit in the fine sand fill materials (well 34-MW20) and for the confined aquifer (well 34-MW24). The hydraulic conductivities estimated by using the Bouwer and Rice and Cooper, Bredehoeft, and Papadopulos methods for each monitoring well are summarized in Table C-1. Attachment C-2 provides the AQTESOLV printouts of the details of slug test interpretations. Attachment C-3 contains the pressure transducer data.

As shown in Attachment C-2, the displacement-versus-time data were plotted on semi-logarithmic axes and the straight-line Bouwer and Rice or curvilinear Cooper, Bredehoeft, and Papadopulos solutions were matched to the data. The resulting estimates of hydraulic conductivity are provided at the bottom of each page that summarizes the interpretation of each individual slug test. The results of interpretation of the slug tests in well 34-MW24 using the Cooper, Bredehoeft, and Papadopulos solution include transmissivity and aquifer coefficients values. The hydraulic conductivity for this solution was obtained by dividing transmissivity by 10 feet (a portion of thickness of confined unit in which well 34-MW24 is screened).

There is one page per slug test for well 34-MW20 and two pages of the results for each of the four tests conducted in well 34-MW24 for each interpretation method. The first page presents the results of interpretation using the Bouwer and Rice method and the second presents the results obtained by the Cooper, Bredehoeft, and Papadopulos method.

The estimated average hydraulic conductivity based on three slug out tests in well 34-MW20 is 22.3 feet per day (ft/day). This estimate is typical of sandy materials (see Table C-1). The estimated average hydraulic conductivity based on two slug-in and two slug-out tests in well 34-MW24 is 0.06 ft/day (Bouwer and Rice method) and 0.05 ft/day (Cooper, Bredehoeft, and Papadopulos method). Based on averaging the results from both methods, the hydraulic conductivity for well 34-MW24 is 0.052 ft/day. The average aquifer coefficients value was estimated at 0.002. The estimated hydraulic conductivity for well 34-MW24 is representative of fine and silty sands; the estimated S value corresponds to the higher-end estimates for a confined aquifer.

#### **C4.0 CONCLUSIONS**

The slug tests conducted in wells 34-MW20 and 34-MW24 provided the estimates of hydraulic parameters of fine sand fill materials and confined unit of fine sand beneath the site, respectively. The average hydraulic conductivity for fill materials is estimated at 22.3 ft/day (well 34-MW20). The average hydraulic conductivity and S value for the confined unit of fine sand are 0.052 ft/day and 0.002, respectively (well 34-MW24).

MW-24 SLUG OUT TEST 2

Data Set: C:\...MW-24\_OUT2\_CBP.aqt

Date: 04/08/07

Time: 23:34:47

PROJECT INFORMATION

Company: Tetra Tech EM Inc.

Client: Navy

Test Location: Site 34, Alameda

Test Well: MW-24

Test Date: 07/07/2006

AQUIFER DATA

Saturated Thickness: 20. ft

Anisotropy Ratio (Kz/Kr): 1.

WELL DATA (MW-24)

Initial Displacement: 2.675 ft

Casing Radius: 0.08333 ft

Wellbore Radius: 0.3438 ft

Well Skin Radius: 0.3438 ft

Screen Length: 10. ft

Total Well Penetration Depth: 10. ft

Gravel Pack Porosity: 0.25

SOLUTION

Aquifer Model: Confined

Solution Method: Cooper et al.

T = 0.3168 ft<sup>2</sup>/day

S = 0.002951

**ATTACHMENT C-3**

**PRESSURE TRANSDUCER DATA**

Test 1 MW-20

In-Situ Inc. Hermit 3000

Report generated: 07/07/06 12:54:20  
 Report from file: C:\WIN-SITU\Data\SN45352 2006-07-07 123355 Test #3.bin  
 DataMgr Version 3.70

Serial number: 00045352  
 Firmware Version 7.10  
 Unit name: Hermit 3000

Test name: Test 1 MW-20

Test defined on: 07/07/06 12:32:45  
 Test started on: 07/07/06 12:33:55  
 Test stopped on: 07/07/06 12:58:09  
 Test extracted on: 07/07/06 12:58:21

Data gathered using Logarithmic testing  
 Maximum time between data points: 25.0000 Minutes.  
 Number of data samples: 104

TOTAL DATA SAMPLES 104

Channel number [1]  
 Measurement type: Pressure  
 Channel name: PXD-261-65491  
 Linearity: 0.2435000  
 Scale: 29.6194000  
 Offset: -0.0449000  
 Warmup: 50

Channel number [0]  
 Measurement type: Barometric Pressure  
 Channel name: Barometric  
 Linearity: 0.0000000  
 Scale: 0.0000000  
 Offset: 0.0000000  
 Warmup: 50

Mw-24 Slug Out Test 1

In-Situ Inc.

MiniTroll Pro

Report generated: 3/6/2007 9:07:53  
 Report from file: ...ISN08573 2007-03-01 112636 mw24 slugout 1.bin  
 Win-Situ Version 4.47

Serial number: 8573  
 Firmware Version 3.09  
 Unit name:

Test name: mw24 slugout 1

Test defined on: 3/1/2007 10:32:10  
 Test started on: 3/1/2007 11:26:36  
 Test stopped on: 3/1/2007 13:22:29  
 Test extracted on: N/A N/A

Data gathered using Logarithmic testing

Maximum time between data points: Seconds.  
 Number of data samples: 143

TOTAL DATA SAMPLES 143

Channel number [1]

Measurement type: Temperature  
 Channel name:

Channel number [2]

Measurement type: Pressure  
 Channel name: slugin1  
 Sensor Range: 30 PSIG.  
 Specific gravity: 1  
 Mode: TOC  
 User-defined reference: 0 Feet H2O  
 Referenced on: channel definition.  
 Pressure head at reference: 24.68 Feet H2O

Notes  
 Concentrations in milligrams per kilogram  
 \* Duplicate of sample in previous row  
 \*\* Sediment sample  
 \* Duplicate analysis not within control limits  
 B Reported value less than contract required detection limit, but greater than instrument detection limit  
 E Estimated because of interference  
 R Foot below ground surface  
 J Estimated concentration  
 N Spiked sample recovery not within control limits  
 U Not detected

**TABLE D-10. TOTAL PETROLEUM HYDROCARBONS IN SOIL (continued)**

Appendix D, Remedial Investigation Report, Installation Restoration Site 34, Alameda Point, Alameda, California

Point Name	Sample Identification	Sample Date	Sample Depth (ft)	Oil and Grease	Diesel	Jet Fuel 5	Motor Oil	Gasoline
------------	-----------------------	-------------	-------------------	----------------	--------	------------	-----------	----------

## Notes:

Concentrations in milligrams per kilogram

+	Duplicate of sample in previous row
++	Sediment sample
ft	Foot below ground surface
H	Pattern is in the heavier hydrocarbon end of the analyte's range in the standard
J	Estimated concentration
L	Pattern is in the lighter hydrocarbon end of the analyte's range in the standard
M	Pattern resembles motor oil
U	Not detected
Y	Resembles a fuel pattern but does not match the standards
Z	Pattern does not resemble total petroleum hydrocarbon pattern

## **F1.0 INTRODUCTION**

This appendix summarizes the chemical and quality control (QC) data gathered during the Remedial Investigation (RI) for Installation Restoration (IR) Site 34, at the former Naval Air Station (NAS) Alameda located in Alameda, California. This appendix discusses QC results of soil, grab groundwater, and groundwater samples collected during the 2006 and 2007 RI sampling activities. Data collected before the RI sampling activities are discussed in the project-specific reports by investigation activity, which include a Phase 1 Environmental Baseline Survey (EBS) (Environmental Resources Management-West, Inc. 1994), removal of fuel lines (IT Corporation [IT Corp.] 1999), a Phase 2a and 2b EBS (IT Corp. 2001), and a site investigation (Bechtel Environmental, Inc. 2003).

The appendix consists of the following six sections, which follow this introduction:

- Section F2.0 provides an overview of the data validation methodology.
- Sections F3.0 and F4.0 present the validated results for cursory and full review.
- Section F5.0 summarizes the precision, accuracy, representativeness, completeness, and comparability (PARCC) evaluation.
- Section F6.0 presents conclusions on the overall evaluation of the chemical data.
- Section F7.0 lists the documents used to prepare this appendix.

Tables that provide supplementary information to this appendix are presented after Section F7.0.

## **F2.0 DATA VALIDATION METHODOLOGY**

Data validation is a systematic process for reviewing and qualifying data against a set of criteria to determine if they are adequate for their intended use. Reviewing and evaluating all analytical data for their PARCC parameters verifies adequacy. The laboratory analytical data were validated according to procedures outlined in the following documents:

- U.S. Environmental Protection Agency (EPA) Contract Laboratory Program (CLP) National Functional Guidelines for Organic and Inorganic Data Review (EPA 1999, 2004)
- Data Validation Statement of Work (Tetra Tech EM Inc. [Tetra Tech] 2001)
- Remedial Investigation Work Plan, IR Site 34 (SulTech 2006)
- Documentation associated with the analytical methods for each analysis

Data validation occurred in two stages: (1) a cursory review of the analytical reports and the quality assurance (QA) and QC information was conducted on 100 percent of the chemical data, and (2) a full review of the analytical reports, the QA and QC information, and the associated raw data was conducted on 10 percent of the chemical data (see Sections F3.0 and F4.0, respectively). The cursory review evaluated the effect of the most critical QA and QC information (such as holding times, calibration requirements, and spiking accuracy) on the data. The full review evaluated additional QA and QC criteria and used the raw data to check calculations and analyte identifications. At each stage of validation, qualifiers were assigned to the results in the electronic database in accordance with EPA guidelines (EPA 1999, 2004) and the RI Work Plan (SulTech 2006).

The overall objective of data validation was to determine if the quality of the chemical data set was adequate for its intended purpose, as defined by the PARCC parameters in EPA guidance (EPA 2002). The following tasks were completed to assess PARCC parameters:

- Review precision and accuracy of laboratory QC data
- Review precision and accuracy of field QC data
- Review the overall analytical process, including holding times, calibrations, analytical or matrix performance, and analyte identification and quantitation
- Assign qualifiers to data affected when QA and QC criteria were not achieved
- Review and summarize implications of the frequency and severity of qualifiers in the validated data

This appendix includes the validation findings for the following samples collected during the 2006 and 2007 RI sampling activities:

- 132 soil samples
- 19 grab groundwater samples
- 10 groundwater monitoring well samples

In addition to the soil and groundwater samples, QC samples were analyzed, including equipment rinsate blanks, source blanks, and trip blanks. Chemical analyses on all sample matrices were subjected to similar QA requirements and standardized methods.

The chemical analytical program for the 2006 and 2007 RI sampling activities included the following analyses and methods:

- Volatile organic compounds (VOC) by the SW-846 EPA Methods 5035 and 8260B (EPA 1996)
- Semivolatile organic compounds (SVOC) by the SW-846 EPA Method 8270C (EPA 1996)
- Polycyclic aromatic hydrocarbons (PAH) by SW-846 EPA Method 8270C Selective Ion Monitoring (EPA 1996)
- Organochlorine pesticides by SW-846 EPA Method 8081A (EPA 1996)
- Polychlorinated biphenyls (PCB) by SW-846 EPA Method 8082 (EPA 1996)
- Chlorinated herbicides by SW-846 EPA Method 8151A (EPA 1996)
- Total petroleum hydrocarbons (TPH) as purgeables (TPH-p) by the State of California Leaking Underground Fuel Tank (LUFT) Field Manual (State of California 1989) and by SW-846 Methods 5035 and 8015A (EPA 1996)
- TPH as extractables (TPH-e) according to the State of California LUFT Field Manual (State of California 1989) and by SW-846 EPA Method 8015A (EPA 1996)
- Metals by SW-846 EPA Method 6020/7470A&7471A (EPA 1996)
- Hexavalent chromium by EPA Method 7196A (EPA 1996)
- Total dissolved solids (TDS) by Methods for Chemical Analysis of Water and Wastes 160.1 (EPA 1983)

Analytical methods, sample holding times and containers, and preservation requirements are listed by sample matrix in Table F-1.

### **F3.0 CURSORY REVIEW**

Cursory review of the analytical reports for the methods included evaluating the following parameters, as applicable: holding times, initial and continuing calibrations, laboratory and field blanks, accuracy, laboratory precision, and analytical or matrix performance. An overall assessment of the data was also conducted. Cursory review components and the results of each specific review are discussed in Sections F3.1 through F3.6 of this appendix. Section F3.7 discusses results reported below the contract-required quantitation and detection limits (CRQL and CRDL, respectively). Tables summarizing the data validation criteria, findings, and evaluation follow Section F7.0 of this appendix. Only chemicals with qualified data are included in the tables that present data qualification findings.

### **F3.1 HOLDING TIMES**

One objective of data validation was to assess the validity of the chemical data set based on compliance with technical holding times: the maximum time allowable between sample collection and, as applicable, sample extraction, preparation, and analysis. The Clean Water Act of 1984 (Title 40 *Code of Federal Regulations* Part 136) established technical requirements for water holding times and preservation. For methods not covered by Title 40 *Code of Federal Regulations* Part 136, the holding times used for validation purposes were either recommended in the CLP guidelines for data review (EPA 1999, 2004) or were specified in the RI Work Plan (SulTech 2006). Table F-2 summarizes all applicable technical holding time requirements by analysis and matrix, and identifies criteria for estimating and rejecting analytical results.

For analytical methods with required holding times greater than 1 week, samples extracted, prepared, or analyzed outside of specified holding times were qualified as “Jh” (indicating the results were estimated values) (EPA 1999, 2004). When these holding times were grossly exceeded (more than double the specified holding time), nondetected results were qualified as “Rh” (indicating the results were rejected), while detected results were qualified as estimated (Jh). For analytical methods with required holding times of less than 1 week, samples extracted, prepared, or analyzed outside of specified holding times were again qualified as estimated (Jh). When these holding times were exceeded by more than 1 week (usually more than double the specified holding time), nondetected results were rejected (Rh) and detected results were estimated (Jh).

Table F-3 summarizes the holding time exceedances for the soil samples. Of all 2006 and 2007 analytical data from IR Site 34, 0.27 percent was qualified as estimated due to holding times outside of the specified criteria. The extraction holding time for one soil sample for pesticides and PCB analysis was exceeded. For groundwater analysis, the extraction holding time for analysis of five water samples for TPH-e was exceeded. No 2006 or 2007 data were qualified as rejected because of holding time exceedances.

### **F3.2 CALIBRATION**

Laboratory instrument calibration requirements were established to confirm the analytical instruments could produce acceptable qualitative and quantitative data for target chemicals. Initial calibration demonstrates the instrument is capable of acceptable performance at the beginning of an analytical run while producing a linear curve. Continuing calibration demonstrates the instrument is capable of repeating the performance established in the initial calibration (EPA 1999, 2004). Table F-4 summarizes all applicable calibration requirements by analysis and includes criteria for estimating and rejecting analytical results when calibration requirements are violated.

### **F3.2.1 Inorganic Analyses**

Initial calibration review for inorganic (metals) analyses included evaluating criteria for the curve's correlation coefficient and initial calibration verification (ICV) percent recoveries (%R). The ICV %R verifies the analytical system is operating within established calibration criteria at the beginning of an analytical run. Most metals were analyzed using an inductively coupled plasma (ICP) atomic emission spectrophotometer. The ICP atomic emission is inherently linear over a wide concentration range, thus it does not require multiple initial calibration standards (mandatory for most other methods). The continuing calibration review included an evaluation of the criteria for continuing calibration verification (CCV) %Rs. The CCV %R verifies the analytical system is operating within the established calibration throughout the analytical run.

Samples that were analyzed when the calibration requirements were not met were qualified as "Jc," indicating the results were estimated (EPA 2004). In general, inorganic data are not rejected because of calibration violations except in the professional judgment of the data reviewer. No 2006 or 2007 inorganic data were qualified because of calibration violations.

### **F3.2.2 Organic Analyses**

Initial calibration review for organic analyses included evaluating percent relative standard deviation (%RSD), relative response factors (RRF), and retention times. The %RSD indicates the analytical system's linearity over an established concentration range. The RRF identifies the sensitivity of the analytical system to a particular target chemical. Retention time reflects the analytical system's stability. Retention time stability is particularly important in analyses for pesticides and PCBs, for which positive identification is made when a peak falls within the specified retention time "windows" on two dissimilar columns. The continuing calibration review included an evaluation of percent difference (%D), RRFs, and retention times. The %D measures the analytical system's precision and was calculated by comparing the daily RRF with the RRF established in the initial calibration.

Samples analyzed when calibration requirements were not met were qualified as "Jc" (indicating the results were estimated) (EPA 1999). Samples with nondetected results that were analyzed when RRF requirements were not met were qualified as "Rc" (indicating the results were rejected), while detected results were "estimated Jc" (EPA 1999). Table F-5 summarizes organic and inorganic analytical data qualified because of calibration violations ("Jc" and "Rc"). Of all 2006 and 2007 organic analytical data from IR Site 34, 2.10 percent was qualified as estimated because of calibration violations. No 2006 or 2007 organic data were rejected because of calibration violations.

### F3.3

### LABORATORY AND FIELD BLANKS

Laboratory and field blank samples were analyzed to determine the existence and magnitude of contamination resulting from sample collection or laboratory activities (EPA 1999, 2004). Blanks prepared and analyzed in the laboratory consisted of calibration blanks and method and preparation blanks. Field blanks consisted of equipment rinsate blanks and source blanks. If a problem with any blank existed, all associated data were carefully evaluated to determine if the sample data were affected. The following table summarizes the purpose of each laboratory and field blank.

<b>Blank Type</b>	<b>Purpose of Blank</b>
Calibration blank	Evaluate analytical instruments for possible laboratory contamination
Method and preparation blank	Evaluate extraction or preparation procedures for possible laboratory contamination
Equipment blank	Evaluate decontamination procedures as a possible route for field contamination
Trip blank	Determine whether shipping the samples introduces contamination (for volatiles analyses)
Source blank	Evaluate source water used in equipment rinsate blanks for possible contamination

At a minimum, calibration and preparation blanks were analyzed once every analytical period for each instrument. Method and preparation blanks were extracted (or prepared) at a frequency of 1 per extraction or preparation batch per matrix or per 20 samples, whichever was greater (EPA 1999, 2004). Equipment rinsate blanks for a specified set of sample analyses were collected weekly for each sampling task because each sampling task used different sample collection devices. Equipment rinsate blanks were analyzed for the same chemicals as the samples collected with the equipment. Source blanks were collected for each new lot of water used for the equipment rinsate blanks. Trip blanks were shipped with each cooler containing water samples for VOC and TPH-purgeables analyses. Table F-6 summarizes the qualifications made to the data based on laboratory and field blanks.

When laboratory blank contamination was identified, sample results were compared with an action level of 5 times the highest level detected in the associated laboratory blank. Only detected results of less than the action level for the laboratory blank contaminant were considered nondetected either at the level of the original result or at the CRQL (organic samples only), whichever was higher (EPA 1999, 2004). The data were qualified as "UJb," indicating the results were nondetected and reflected a detection or quantitation limit that may have been raised because of low-level laboratory blank contamination. As shown in Table F-6, laboratory contamination was qualified in only 1.67 percent of the 2006 and 2007 data.

Some chemicals, including acetone, 2-butanone, methylene chloride, and phthalates, are identified as common laboratory contaminants (EPA 1999). These chemicals were qualified as “UJb,” indicating the result is considered nondetected in all samples, including field blanks, which contained levels less than 5 times the reporting limit for those chemicals (Tetra Tech 2001). As shown in Table F-6, acetone, 2-butanone, methylene chloride, bis(2-ethylhexyl)-phthalate, and di-n-butylphthalate, five common laboratory contaminants were found and qualified as nondetected in the samples.

After laboratory blank contamination was assessed, field blanks were evaluated. Where field blank contamination was identified, sample results were compared with an action level of 5 times the highest level found in the associated field blank, except for common laboratory contaminants, which were compared with an action level of 10 times the highest level found in the associated field blank. Only detected results less than the action level for the field blank contaminant were considered nondetected either at the level of the original result or at the CRQL (organic samples only), whichever was higher (EPA 1999, 2004). The data were qualified as “UJf,” indicating the results were considered nondetected and reflecting a detection or quantitation limit that may have been raised because of low-level field blank contamination.

Table F-6 summarizes analytical data qualified because of blank contamination (“UJb” and “UJf”). Of all 2006 and 2007 analytical data from IR Site 34, 1.67 percent was qualified as nondetected because of laboratory contamination and 0.05 percent was qualified as nondetected because of field contamination. Almost one half of the laboratory contamination was a result of common laboratory contaminant detections, while the remaining were mostly low-level metal detections above the method detection limit. The low percentage of chemicals qualified because of detections in field blanks indicates the field equipment decontamination procedures were effective.

### **F3.4 ACCURACY**

One objective of data validation was to assess the accuracy of the chemical data set. Laboratory accuracy was evaluated using recoveries of surrogate spikes, matrix spikes (MS), and laboratory control samples (LCS) or blank spikes. Table F-7 summarizes all applicable accuracy requirements by analysis and includes the criteria for estimating and rejecting analytical results when accuracy requirements are not met. Matrix effects frequently present unique problems in evaluating laboratory accuracy for organic analyses (EPA 1999). In some cases, professional judgment was used in qualifying the data. Any such decisions were clearly identified and documented in the data validation reports.

Organic data affected by surrogate recoveries outside QC limits were qualified as “Ja” (indicating the results were estimated), or in severe cases “Ra” (indicating the results were rejected) (EPA 1999). Table F-8 summarizes investigation analytical data qualified because of accuracy criteria violations in the surrogate spikes (“Ja” and “Ra”). Of the 2006 and 2007 organic analytical data from IR Site 34, 0.27 percent was qualified as estimated because of surrogate spike criteria violations and 0.12 percent was qualified as rejected because of surrogate

spike criteria violations. The rejected data were limited to nondetected chemical results in one pesticide sample.

Organic data affected by MS or blank spike problems were qualified “Je” (indicating the results were estimated), or “Re” (indicating severe matrix problems that resulted in rejected data). For inorganic analyses, laboratory accuracy was evaluated using LCS spike and MS recoveries. In general, data affected by LCS or MS recoveries outside QC limits were qualified as “Je” (indicating the results were estimated). In a few isolated cases where LCS or MS recoveries were very low (less than 50 and 30 percent, respectively), the affected nondetected data were qualified as “Re” (indicating the results were rejected) (EPA 2004).

Table F-9 summarizes analytical inorganic and organic data qualified because of accuracy criteria violations in MSs, LCSs, and blank spikes (“Je” and “Re”). Of all 2006 and 2007 analytical data from IR Site 34, 2.45 percent was qualified as estimated because of accuracy criteria violations. No 2006 or 2007 data were qualified as rejected due to accuracy criteria violations.

### **F3.5           PRECISION**

Another objective of data validation was to assess the precision of the chemical data set. Laboratory precision was evaluated by the relative percent differences (RPD) between the MSs and matrix spike duplicates (MSD) in organic analyses, and by the RPDs between the samples and the sample duplicates in inorganic analyses. For organic analyses, RPDs were used to evaluate overall precision and were not used specifically to qualify data. Precision goals for organic analyses can be found in the RI Work Plan (SulTech 2006). For inorganic analyses, sample and sample duplicate RPDs were used to indicate the laboratory’s analytical precision within a sample delivery group for that matrix. Inorganic sample and sample duplicates were reviewed according to the following criteria (EPA 2004):

- An RPD criterion of plus or minus 20 percent was used for aqueous sample values of greater than 5 times the reporting limit
- An RPD criterion of plus or minus 35 percent was used for nonaqueous sample values of greater than 5 times the reporting limit
- An absolute difference of plus or minus the reporting limit was used for aqueous sample values of less than 5 times the reporting limit
- An absolute difference of plus or minus 2 times the reporting limit was used for nonaqueous sample values of less than 5 times the reporting limit

Inorganic data affected by sample and sample duplicate RPDs outside QC limits were qualified as “Jd” (indicating the results were estimated) (EPA 2004). Data were not rejected based on precision criteria violations. Table F-10 summarizes analytical data qualified because of

precision criteria violations (“Jd”). Of all 2006 and 2007 analytical data from IR Site 34, 0.51 percent was qualified as estimated because of precision criteria violations.

### **F3.6 ANALYTICAL AND MATRIX PERFORMANCE**

In addition to the data quality requirements discussed, further laboratory QA and QC criteria were evaluated in the cursory review. These additional criteria were primarily related to analytical and matrix performance and are summarized in Table F-11.

For VOC and SVOC analyses, internal standard performance was evaluated. Internal standard performance criteria are used to determine if gas chromatography and mass spectroscopy (GC/MS) sensitivity and response are stable during every analytical run. Matrix effects, however, frequently present unique problems in evaluating analytical performance, and matrix effects may affect internal standard performance. Internal standard requirements are based on a comparison of the sample’s internal standard area with the same internal standard area found in the daily calibration standard. Internal standard area counts in the sample must be within 50 to 150 percent, and internal standard retention times must not vary by more than plus or minus 30 seconds from the internal standard in the associated daily calibration standard (EPA 1999).

Organic data affected by internal standard criteria violations were qualified as “Ji” (indicating the results were estimated). Organic data with any internal standard area(s) less than 10 percent of the internal standard’s area in the associated daily standard were qualified as “Ri” or “Ji.” “Ri” indicated nondetected results were rejected, and “Ji” indicated detected results were estimated. Table F-12 summarizes organic analytical data that were qualified because of internal standard performance criteria violations (“Ji” and “Ri”). Of all 2006 and 2007 analytical data from IR Site 34, 0.38 percent was qualified as estimated because of analytical or matrix performance violations. The matrix performance criteria violations were limited to low internal standard areas in seven PAH samples and two SVOC samples. Each of the samples were reanalyzed to confirm the initial result and verify matrix interference problems. No data were qualified as rejected because of analytical or matrix performance violations.

In addition to the analytical or matrix performance criteria outlined, some of the data were qualified with the general qualifiers (“Jj,” “UJj,” and “Rj”) for other analytical or matrix problems encountered, such as concentrations reported at a level slightly greater than the largest calibration standard. These results should be considered qualitatively and quantitatively reliable, even though the laboratory protocol requires sample dilution for results reported over the calibration range. The sample results were qualified during the data validation according to the professional judgment of the reviewer; these results are well documented in the validation reports.

For inorganic analysis, ICP serial dilutions were evaluated. ICP serial dilution analysis evaluated if matrix interference existed and if the accuracy of the analytical data was affected. The criterion for acceptability is a %D of less than 10 percent when the results of a five-fold dilution are compared with the results from the undiluted sample. This criterion applies only

when the concentration of the element in the undiluted sample is at least 50 times that of the instrument detection limit.

Inorganic data affected by any of the previously mentioned criteria violations were qualified as “Jj” (indicating the results were estimated). Table F-13 summarizes the inorganic and organic analytical data qualified because of analytical or matrix performance criteria violations (“Jj” and “Rj”). Of all 2006 and 2007 analytical data from IR Site 34, 0.89 percent was qualified as estimated because of analytical or matrix performance violations. No 2006 or 2007 analytical results were rejected because of analytical or matrix performance violations. Organic data qualified as “Jj” were limited to RPD exceedances in the results reported between two columns used during pesticide analysis. Inorganic data qualified as “Jj” were estimated because of metals ICP serial dilutions that exceeded QC limits. The serial dilution problems are attributed to matrix interference rather than analytical performance issues.

### **F3.7 RESULTS BELOW THE CONTRACT-REQUIRED QUANTITATION AND DETECTION LIMITS**

For organic analyses, the analytical instruments can make reliable qualitative identification of chemicals at concentrations below the CRQL. For CLP metals analysis, the ICP can make reliable qualitative identification of chemicals above the instrument detection limit but below the CRDL. Detected results below the CRQL and CRDL are considered quantitatively uncertain. Sample results below the CRQL and CRDL were reported by the laboratory with a “J” qualifier (for organic data) or a “B” qualifier (for inorganic data) and were subsequently qualified during the data validation process as “Jg” (indicating the results were estimated). Table F-14 summarizes data qualified as estimated because of results reported below the CRQL and CRDL. Of all 2006 and 2007 analytical data from IR Site 34, 4.33 percent was qualified as estimated because of detected results reported below the CRQL or CRDL.

### **F4.0 FULL REVIEW**

A full review was conducted on a random 10 percent of 2006 and 2007 chemical data for IR Site 34. Full review includes all the elements of a cursory review (see Section F3.0), plus the following additional items, as applicable:

- Method compliance, instrument performance check samples, cleanup performance, system performance check samples, system performance, ICP interference check samples, and overall assessment of the data
- Target chemical identification
- Chemical quantitation
- Detection and quantitation limit verification

Criteria for data qualification during the full review are listed in the EPA guidelines (EPA 1999, 2004), the RI Work Plan (SulTech 2006), and associated analytical methods. Sections F4.1 through F4.4 discuss the full review components and the results of each specific assessment.

#### **F4.1 ADDITIONAL ANALYTICAL AND MATRIX PERFORMANCE**

In addition to cursory review data quality requirements (see Section F3.0), full review includes additional verification of the data relative to the established QA and QC criteria. The additional full review requirements are primarily related to analytical and matrix performance. For organic analyses, the following requirements were evaluated, as applicable: instrument performance check samples and cleanup performance check samples for florisil cartridges and gel-permeation chromatography (GPC), as applicable to SVOCs, pesticides, PCBs, and TPH-extractables. Organic performance requirements are listed in Table F-11.

For VOCs and SVOCs analyses, GC/MS instrument performance check samples were analyzed to confirm mass resolution, identification, and, to some degree, sensitivity. Specifically, minimum and maximum ion abundance requirements must be met for decafluorotriphenylphosphine. Gas chromatography and electron capture detector instrument performance check samples (for pesticides and PCBs) were analyzed to verify adequate resolution and instrument sensitivity. Analytical requirements for the target chemicals and surrogates include the criteria for RPD (between the true and actual values), chromatographic resolution, and percent breakdown for 4,4'-dichlorodiphenyltrichlorethane and endrin (EPA 1996, 1999).

For SVOCs, pesticides, PCBs, and TPH-e analyses, cleanup check samples were analyzed to verify the recovery of the target chemicals through the cleanup processes. The GPC cleanup process removes matrix interferences from sample extracts before analysis. A blank spike is run through the GPC column, and the %R is calculated to check these processes. GPC is checked weekly (EPA 1996, 1999).

For inorganic analyses, the following requirements were evaluated, where applicable: ICP interference check samples, graphite furnace atomic absorption (GFAA) duplicate injections, GFAA analytical spikes, and GFAA method of standard additions. The ICP interference check sample verifies the validity of the laboratory's interelement and background correction factors. High concentrations of aluminum, iron, calcium, and magnesium can affect sample results if the interelement and background correction factors have not been optimized. Incorrect correction factors may result in false positives, false negatives, or biased results. GFAA duplicate injections and GFAA analytical spikes establish the precision and accuracy of the individual analytical determinations. Method of standard additions is used in instances where the GFAA analytical spike did not meet the required QC limits and the initial concentration of the target chemical is greater than 50 percent of the spike concentration. A linear curve is prepared using three injections of the sample plus increasing concentrations of spikes: 50 percent, 100 percent, and 150 percent of the sample's concentration. The absolute value of the x-intercept of the curve is reported as the sample concentration (EPA 1996).

In general, data affected by any of the previously mentioned criteria violations were qualified as "Jj" (indicating that the results were estimated). These data are included in Table F-13.

#### **F4.2 CHEMICAL IDENTIFICATION**

Qualitative criteria for chemical identification have been established to minimize erroneous identification of chemicals. An erroneous identification can be either a false positive (reporting a chemical present when it is not) or a false negative (not reporting a chemical that is present). For VOCs and SVOCs analyses, identification was achieved by comparing the sample's mass spectra and retention time to the standard's mass spectra and retention time. For positive identification, the chemical's mass spectra must contain all the standard's ions with relative intensities greater than 10 percent and agree within plus or minus 20 percent of the standard ion's relative intensities. In addition, the mass spectra must not contain any unaccounted ions with relative intensities greater than 10 percent. Moreover, the retention time must be within plus or minus 0.06 relative retention time units of the standard component's retention time (EPA 1996, 1999).

For pesticides, PCBs, and herbicides analyses, positive identification was made when a peak fell within the specified retention time "windows" on two dissimilar columns. Surrogates and MS/MSDs also were strictly evaluated to identify any retention time shifts. An RPD value between the two columns was calculated to verify quantitative agreement. Detected results with RPDs greater than 50 percent were qualified as "Jj" (indicating the results were estimated). Misidentified results below the CRQL were raised to the quantitation limit and considered nondetected. In some cases, professional judgment was used in qualifying the result as estimated ("Jj") or nondetected ("UJj"). Any such decisions were clearly identified and documented in the data validation reports.

For TPH-p and TPH-e, positive identification was made when a response was recorded in the appropriate retention time windows for the particular analysis. For TPH-p and TPH-e, a more definitive fingerprinting of the chromatographic peaks for the type of petroleum product was used to identify fuels. When the chromatographic peaks displayed a petroleum fuel product, such as gasoline, diesel, or motor oil, the data were qualified as "Y," indicating the results were a petroleum fuel. When a single peak or pattern was detected that did not resemble typical fuel patterns, the data were qualified as "Z." Additionally, the following qualifiers were used to identify the particular petroleum product results:

- "D," indicating a pattern resembling diesel
- "M," indicating a pattern resembling motor oil
- "G," indicating a pattern resembling gasoline

- “L,” indicating a pattern in the lighter hydrocarbon end of the chemical’s range in the standard
- “H,” indicating a pattern in the heavier hydrocarbon end of the chemical’s range in the standard

When a single peak or patterns were detected that did not resemble typical fuel patterns, the data were qualified as “Z,” indicating the results did not represent a typical fuel.

For TPH-e, diesel- and motor oil-ranges overlap. When both are present in a sample, a line is drawn between the two petroleum pattern baselines to perform quantitation. The area of each pattern is then quantitated for the particular fuel that it best represents.

For metals, hexavalent chromium, and TDS analyses, positive identification was made when the instrument registered a measurable response while operating under the method-specified analytical parameters. In these cases, the instrument’s accuracy in chemical identification is indirectly verified by assessing the instrument’s performance.

Table F-13 summarizes the analytical data qualified because of chemical identification violations (“Jj” and “UJj”) and analytical and matrix performance violations for inorganic and organic methods (see Section F3.6).

#### **F4.3 CHEMICAL QUANTITATION**

All applicable raw data were reviewed to verify positive results and the reported detection or quantitation limits. A minimum of 10 percent of the calculations were evaluated and recalculated for reproducibility. Raw data reviewed included the following sources, as applicable: extraction and preparation logbooks, cleanup logbooks, spike and standard preparation logbooks, instrument printouts, strip chart recordings, chromatograms, and quantitation reports. The following data sources also were evaluated, as applicable: sample dilutions, concentrations, analytical split samples, cleanup activities, and percent moisture. Review of the raw data showed that the chemical analytical results from 2006 and 2007 for IR Site 34 were properly quantitated.

#### **F4.4 CHEMICAL REPORTING LIMITS**

Chemical reporting limits are directly affected by dilutions and percent moisture. All soil sample results were reported with detection or quantitation limits slightly raised after correction for percent moisture. In addition, detection or quantitation limits for both soil and water samples were raised by the dilution factor when samples required dilution for analysis. Sample dilution was necessary when high levels of a chemical were present or when matrix problems occurred during sample extraction or analysis.

Review of this investigation chemical data set identified several soil samples for organic analyses requiring dilutions necessary to quantify chemicals within the calibration range of the analysis. Necessary sample dilutions increased the average soil sample quantitation limits above the reporting limit goals for metals, VOCs, SVOCs, PAHs, and pesticides, as well as SVOCs in water samples. Because these samples contained higher concentrations of chemicals, dilutions were necessary to quantitate chemical results; therefore, the data were not compromised by increased detection limits. Most of the other soil and water results did not require dilution for chemical quantitation; therefore, very few reporting detection or quantitation limits were raised for these analyses. Table F-15 summarizes the average reporting limits for this investigation and lists the reporting limits established in the RI Work Plan by matrix (SulTech 2006).

## **F5.0 EVALUATION SUMMARY**

PARCC parameters were reviewed to validate all analytical data. This section discusses the overall data quality, including the PARCC parameters, as determined by the data validation.

### **F5.1 PRECISION**

Precision is a measure of the reproducibility of an experimental value without regard to the true or reference value. The primary indicators of data precision were the RPDs between the MSs and the MSDs in organic analyses, and the RPDs between the samples and the sample duplicates in inorganic analyses. The following list summarizes the precision of the 2006 and 2007 data for IR Site 34:

- All organic MS/MSD and LCS/LCS duplicate RPDs were within QA and QC acceptance criteria, indicating that the methods were consistently sound.
- Sample and sample duplicate RPDs for metals and TDS analyses were within the QA and QC criteria for water samples. Sample and sample duplicate RPDs for hexavalent chromium were within the QA and QC criteria for soil samples. Five metals were qualified as estimated because sample duplicate RPD criteria were exceeded; however, because of the heterogeneity of soil samples and debris field samples these exceedances are not considered to have an affect on the data quality.

### **F5.2 ACCURACY**

Accuracy assesses the proximity of an experimental value to the true or reference value. The primary accuracy indicators were the recoveries of surrogate spikes, MS, and LCS spikes. The following list summarizes the accuracy of the 2006 and 2007 data for IR Site 34:

- For VOC, SVOC, PAH, herbicide, and TPH-e analyses, the surrogate spike recoveries were within QA and QC criteria. Several soil PCB and TPH-p samples were qualified as estimated because of surrogate recovery exceedances. Several groundwater pesticide, PCB, and TPH-p samples also were qualified as estimated because of surrogate recovery exceedances. The nondetected chemicals in one pesticide sample were rejected because of surrogate spike recovery violations. Only one sample was rejected for surrogate recovery exceedances, indicating the organic analyses were consistently precise.
- For VOC, PCB, pesticide, herbicide, TPH-p, and TPH-e analyses, the MS and LCS spike recoveries were within QA and QC criteria. One soil PAH sample was qualified as estimated because of MS recovery exceedances and one groundwater SVOC sample, 1-nitrophenol, was qualified as estimated because of MS recovery exceedances. Organic data were not rejected based on MS or LCS spike recovery violations, indicating the organic analyses were consistently precise.
- For inorganic analyses, several metals and TDS samples were qualified as estimated for MS or LCS spike recovery exceedances; the LCS spike and MS recoveries were generally within QA and QC criteria, indicating these methods were accurate. No inorganic data were rejected based on accuracy violations.

### **F5.3 REPRESENTATIVENESS**

Representativeness refers to the ability of sample data to reflect true environmental conditions. Determinants of representativeness include sampling locations, frequency, collection procedures, and possible compromises to sample integrity (such as cross-contamination) that can occur during collection, transport, and analysis of samples. Selection of representative sampling locations is important for obtaining samples that accurately show site conditions. Correct sample collection, transport, and analytical procedures are important to ensure the samples closely resemble the medium sampled and to minimize contamination.

For 2006 and 2007 sampling activities at IR Site 34, the sampling locations, frequency, and collection protocols were described in the RI Work Plan (SulTech 2006). The protocols followed standard accepted methods of site characterization and were approved by the regulatory agencies. Thus, with respect to accepted site characterization approaches, existing guidance, and regulatory compliance, the 2006 and 2007 sampling activities at IR Site 34 met all relevant requirements for data representativeness.

### **F5.4 COMPLETENESS**

Completeness is defined as the percentage of analytical results considered valid. Valid data are those identified as acceptable or qualified as estimated (J) during the data validation process. Data qualified as rejected (R) are considered unusable and not valid. For 2006 and 2007 data for

IR Site 34, only the nondetected results in one pesticide sample (0.12 percent of the data) was qualified as rejected during the cursory or full data validation review.

The assessment of completeness consisted of comparing the amount of acceptable and usable results with the total number of results. The data evaluated in this appendix indicate a completeness of 99.9 percent. The completeness goal of 90 percent for field samples and laboratory samples established in the RI Work Plan (SulTech 2006) was exceeded.

## **F5.5 COMPARABILITY**

Comparability is a qualitative assessment of how well one data set compares to another. The important determinants of comparability include the uniformity of sampling activities, analytical procedures, data reporting, and data validation. The use of EPA protocols, specific and well-documented analyses, approved laboratories, and the standardized process of data review and validation give the IR Site 34 data a high degree of analytical comparability. The use of well-established analytical protocols ensures the data are comparable.

## **F6.0 CONCLUSIONS FOR DATA QUALITY AND DATA USABILITY**

Although some qualifiers were added to the data, a final review of the data set with respect to the EPA data quality parameters (see Section F5.0) indicated the data are of high overall quality. The data meet all the requirements of the PARCC data quality indicators described in EPA guidance for quality assurance project plans (EPA 2002) and are usable for risk assessment. The overall assessment of the sampling program, QA and QC data, data review, and data validation results (see Sections F3.0 and F4.0) indicates that these investigation data are of acceptable PARCC. All supporting documentation and data are available upon request, including cursory and full validation reports and the database containing all sample results.

The EPA Risk Assessment Guidance for Superfund (RAGS) was used to determine the usability of the validated data (EPA 1989). Exhibit 5-5 in RAGS states that data qualified as estimated (J) based on data validation reports should be used in quantitative risk assessments. Although this guidance is specifically for human health risk assessments, the same usability criteria were used for all IR Site 34 data. Except for nondetected results in one pesticide groundwater sample that were qualified as rejected (R), all remaining data were appropriate for use in the RI Report for IR Site 34 and corresponding risk assessment.

**TABLE F-1: ANALYTICAL METHODS, SAMPLE HOLDING TIMES AND CONTAINERS, AND PRESERVATION REQUIREMENTS**  
 Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Parameter	Analytical Method (Ref.)/Technique	Matrix	Holding Time	Container	Preservation
Volatile Organic Compounds	EPA 8260B (EPA 1996)/GC/MS	Water	14 days; 7 days (for unpreserved)	Three × 40-mL vials with Teflon-lined septa caps	Cool to 4 °C ± 2 °C, HCl to pH<2
		Soil	48 hours (until preserved)	5 gram Encore™ Samplers	Cool to 4 °C ± 2 °C
Semivolatile Organic Compounds and PAHs	EPA 8270C (EPA 1996)/GC/MS with Selective Ion Monitoring	Water	7 days to extraction 40 days to analysis	Two 1-L amber glass jars with Teflon-lined lids	Cool to 4 °C ± 2 °C
		Soil	14 days to extraction 40 days to analysis	Glass jars with Teflon-lined lids or brass/acetate sleeves <sup>a</sup>	Cool to 4 °C ± 2 °C
Pesticides, PCBs, and Herbicides	EPA 8081A, 8082, and 8151A (EPA 1996)/GC/ECD	Water	7 days to extraction 40 days to analysis	Two 1-L amber glass jars with Teflon-lined lids	Cool to 4 °C ± 2 °C
		Soil	14 days to extraction 40 days to analysis	Glass jars with Teflon-lined lids or brass/acetate sleeves <sup>a</sup>	Cool to 4 °C ± 2 °C
TPH-p	EPA 8015A (EPA 1996)/LUFT Field Manual (State of California 1989)/GC/FID	Water	14 days	Three 40-mL vials with Teflon-lined septa caps	Cool to 4 °C ± 2 °C, HCl to pH<2
	EPA 5035/8015A and LUFT Field Manual (State of California 1989)/GC/FID	Soil	48 hours	Three EnCore™ Samplers	Cool to 4 °C ± 2 °C
TPH-e	EPA 8015 (EPA 1996)/LUFT Field Manual (State of California 1989)/GC/FID	Water	7 days to extraction 40 days to analysis	Two 1-L amber glass jars with Teflon-lined lids	Cool to 4 °C ± 2 °C
		Soil	14 days to extraction 40 days to analysis	Glass jars with Teflon-lined lids or brass/acetate sleeves <sup>a</sup>	Cool to 4 °C ± 2 °C
Metals	EPA 6010B and 7471A (EPA 1996)/ICPES, GFAA, and CVAA	Water	28 days for mercury 6 months for others	One 1-L polyethylene	HNO <sub>3</sub> to pH<2
		Soil	28 days for mercury 6 months for others	Glass jars with Teflon-lined lids or brass/acetate sleeves <sup>a</sup>	None
Hexavalent Chromium	EPA 7196A (EPA 1996)/Colormetric	Soil	3 days to extraction 24 hours to analysis	Glass jars with Teflon-lined lids or brass/acetate sleeves <sup>a</sup>	None
TDS	MCAWW 160.1 (EPA 1983)/Gravimetric	Water	7 days	One 1-L polyethylene	None

## TABLE F-1: ANALYTICAL METHODS, SAMPLE HOLDING TIMES AND CONTAINERS, AND PRESERVATION REQUIREMENTS (CONTINUED)

Remedial Investigation Report, Installation Restoration Site 34, Alameda Point, Alameda, California

### Notes:

a	When soil samples were collected in sleeves, the ends were covered with Teflon liners and hard plastic caps.
CVAA	Cold vapor atomic absorption
EPA	U.S. Environmental Protection Agency
GC/ECD	Gas chromatography/electron capture detector
GC/FID	Gas chromatography/flame ionization detector
GC/MS	Gas chromatography/mass spectroscopy
GFAA	Graphite furnace atomic absorption
HCl	Hydrochloric acid
HNO <sub>3</sub>	Nitric acid
ICPES	Inductively coupled plasma emission spectroscopy
L	Liter
LUFT	Leaking underground fuel tank
MCAWW	Methods for the Chemical Analysis of Water and Wastes
mL	Milliliter
PAH	Polycyclic aromatic hydrocarbon
PCB	Polychlorinated biphenyl
TDS	Total dissolved solids
TPH-e	TPH-as-extractables
TPH-p	TPH-as-purgeables

**TABLE F-2: HOLDING TIME REQUIREMENTS**

Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Analysis	Matrix	Holding Time <sup>a</sup> Requirement	Data Qualified as Estimated (Jh)	Data Qualified as Estimated (Jh) and Nondetected Data Qualified as Rejected (Rh)
VOCs and TPH-p	Water	Analysis in 14 days	Exceeded by $\leq$ 14 days	Exceeded by > 14 days
	Soil	Analysis in 48 hours Analysis in 7 days (if preserved)	Exceeded by $\leq$ 7 days	Exceeded by > 7 days
VOCs and TPH-p	Unpreserved water	Analysis in 7 days	Exceeded by $\leq$ 7 days	Exceeded by > 7 days
Semivolatile Organic Compounds, PAHs, Pesticides, PCBs, Herbicides, and TPH-e	Water	Extraction in 7 days Analysis in 40 days	Exceeded by $\leq$ 7 days (E) Exceeded by $\leq$ 40 days (A)	Exceeded by > 17 days (E) Exceeded by > 40 days (A)
	Soil	Extraction in 14 days Analysis in 40 days	Exceeded by $\leq$ 14 days (E) Exceeded by $\leq$ 40 days (A)	Exceeded by > 14 days (E) Exceeded by > 40 days (A)
Metals	Water or Soil	Analysis in 28 days for Hg Analysis in 6 months (all others)	Exceeded by $\leq$ 28 days for Hg Exceeded by $\leq$ 6 months (all others)	Exceeded by > 28 days for Hg Exceeded by > 6 months (all others)
Hexavalent Chromium	Soil	Extraction in 3 days Analysis in 24 hours	Exceeded by $\leq$ 7 days	Exceeded by > 7 days
TDS	Water	Analysis in 7 days	Exceeded by $\leq$ 7 days	Exceeded by > 7 days

## Notes:

a Holding times are specified from the date of sample collection.

A Analysis

E Extraction

Hg Mercury

Jh Qualified as estimated because of holding time violations

PAH Polycyclic aromatic hydrocarbon

PCB Polychlorinated biphenyl

Rh Qualified as rejected because of holding time violations

TDS Total dissolved solids

TPH Total petroleum hydrocarbons

TPH-e TPH-as-extractables

TPH-p TPH-as-purgeables

VOC Volatile organic compound

**TABLE F-7: ACCURACY REQUIREMENTS (CONTINUED)**

Remedial Investigation Report, Installation Restoration Site 34, Alameda Point, Alameda, California

Notes:

DCAA	2,4-Dichlorophenylacetic acid
DCB	Dichlorobenzene
Ja	Qualified as estimated because of accuracy violations
PAH	Polycyclic aromatic hydrocarbon
PCB	Polychlorinated biphenyl
Ra	Qualified as rejected because of accuracy violations
SMC	System monitoring compound
TCX	Tetrachloro-m-xylene
TPH	Total petroleum hydrocarbons
TPH-e	TPH as extractables
TPH-p	TPH as purgeables

**TABLE F-11: ANALYTICAL AND MATRIX PERFORMANCE REQUIREMENTS**

Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

Analysis	Performance Requirements	Detected Data Qualified as Estimated (Ji or Jj)	Detected and Nondetected Data Qualified as Estimated (Ji or Jj)	Detected Data Qualified as Estimated (Ji or Jj) and Nondetected Data Qualified as Rejected (Ri or Rj)
Volatile Organic and Semivolatile Organic Compoundss	Sample IS: 50-150%	Sample IS: > 150%	Sample IS: < 50%	Sample IS: < 25%
	IPCS: meet all m/z criteria for volatiles <sup>a</sup> and for semivolatiles <sup>b</sup>	NA	Criteria met for critical abundances, but not for noncritical abundances <sup>a,b</sup>	Criteria not met for all critical abundances <sup>a,b</sup>
PAHs	Sample IS: 50-200%	Sample IS: >200%	Sample IS: <50%	Sample IS: <25%
Pesticides and PCBs	RCM and PEM: meet all criteria <sup>c</sup>	NA	PEM RPD: > ± 25%	RCM %res: <60% PEM %res: <100% PEM RT: > mRT ± 0.05 PEM %break: > 20% for each PEM %break: > 30% for both <sup>d</sup>
	GPC %R: 80-110% <sup>e</sup>	GPC %R: >110%	GPC %R: <80%	GPC %R: <10%
Metals	ICPES serial dilution: %D ≤ 10%	%D > 10% (Jj)	%D > 10% (Jj)	NA

Notes:

a Bromofluorobenzene (BFB)  
 m/z 50: 8.0-40.0% of m/z 95 \*  
 m/z 75: 30.0-66.0% of m/z 95 \*  
 m/z 95: Base peak, 100%  
 m/z 96: 5.0-9.0% of m/z 95  
 m/z 173: < 2.0% of m/z 174  
 m/z 174: 50.0-120.0% of m/z 95  
 m/z 175: 4.0-9.0% of m/z 174  
 m/z 176: 93.0-101.0% of m/z 174  
 m/z 177: 5.0-9.0% of m/z 176  
 \* noncritical abundances

b Decafluorotriphenylphosphine (DFTPP)  
 m/z 51: 30.0-80.0% of m/z 198 \*  
 m/z 68: Less than 2.0% of m/z 69  
 m/z 69: Present  
 m/z 70: Less than 2.0% of m/z 69  
 m/z 127: 25.0-75.0% of m/z 198 \*  
 m/z 197: Less than 1.0% of m/z 198  
 m/z 198: Base peak, 100% relative abundance  
 m/z 199: 5.0-9.0% of m/z 198  
 m/z 275: 10.0-30.0% of m/z 198 \*  
 m/z 365: Greater than 0.75% of m/z 198  
 m/z 441: Present, but less than m/z 443  
 m/z 442: 40.0-110.0% of m/z 198  
 m/z 443: 15.0-24.0% of m/z 442  
 \* noncritical abundances

c RCM % res: > 60.0%  
 PEM % res: = 100%  
 PEM RT: = mRT ± 0.05 minutes  
 PEM %RPD: < 25%  
 PEM %break: < 20.0% (4,4'-DDT and endrin singly)  
 PEM %break: < 30.0% (4,4'-DDT and endrin together)

d Only affected nondetected data are qualified (such as unresolved or degraded compounds).

e Both apply to cleanup performance check samples.

**TABLE F-11: ANALYTICAL AND MATRIX PERFORMANCE REQUIREMENTS (CONTINUED)**  
Remedial Investigation Report, Installation Restoration Site 34, Alameda Point, Alameda, California

Notes:

%break	Percent breakdown
%D	Percent difference
%R	Percent recovery
%res	Percent resolution
DDT	Dichlorodiphenyltrichloroethane
GPC	Gel permeation chromatography
ICPES	Inductively coupled plasma emission spectrophotometer
IPCS	Instrument performance check sample
IS	Internal standard
Ji	Qualified as estimated because of internal standard performance criteria violations
Jj	Qualified as estimated because of analytical or matrix performance criteria violations
m/z	Mass ratio of the specific ion to the base peak
mRT	Mean retention time
NA	Not applicable
PAH	Polycyclic aromatic hydrocarbon
PCB	Polychlorinated biphenyl
PEM	Performance evaluation mixture
RCM	Resolution check mixture
Ri	Qualified as rejected because of internal standard performance criteria violations
Rj	Qualified as rejected because of analytical or matrix performance criteria violations
RPD	Relative percent difference
RT	Retention time

## **GLOSSARY OF TERMS**

---

**Cumulative Distribution Function (CDF)/Empirical Distribution Function (EDF).** The CDF of a set of numerical data is, for each real value of  $x$ , the fraction of observations that are less than or equal to  $x$ . Stated more formally, the CDF gives the probability that a random variable  $X$  is less than or equal to  $x$ , for every value of  $x$ . This function is expressed in mathematical notation as  $F(x) = \text{Prob}(X \leq x)$  for  $-\infty < x < \infty$ . For continuous random variables, the CDF is the integral of its probability density function, and a plot of the CDF resembles an uneven set of stairs. The width of the stairs is the spacing between adjacent data; the height of the stairs depends on how many data have exactly the same value. When the CDF is derived from the observed measurements, it is commonly referred to as the EDF.

**Exposure Point Concentration (EPC).** An estimate of the average concentration of a chemical within a specified area (the exposure unit); also referred to as the concentration term. Because of the inherent uncertainty in estimating the true, but unknown, average concentration at a site, a UCL of the sample mean is used as the EPC in risk assessments.

**Left Censored.** Censoring occurs when data are reported only as being less than a fixed value (usually a detection or reporting limit for environmental data). Data are said to be left censored if the censoring limit is an upper threshold, and the censored values are reported as “less than” the censoring limit. Censored data are also commonly referred to as “nondetect” or “ND” data. Censoring can occur at a single reporting limit or at multiple reporting (or detection) limits.

**Quantile.** Quantiles are a set of “cut points” that divide rank-ordered data into groups of equal numbers of observations. An individual quantile defines a cut point below which a certain number or percentage of the data are found (for example, 90 percent of the measurements in a set lie below the 90th quantile).

**Standard Deviation.** A measure of the spread or dispersion of a set of data. The sample standard deviation is an estimator of the population standard deviation based on a random sample from the population.

**Type I Error.** The probability that a given null hypothesis ( $H_0$ ) will be incorrectly rejected when it is true. The Type I error is represented by the symbol alpha ( $\alpha$ ).

**Upper confidence limit of the mean (UCL).** The one-sided upper confidence limit of the mean. This limit is an upper bound for a random interval and indicates that there is a fixed probability that the true population mean is no larger than this value. Following current U.S. Environmental Protection Agency guidance, the UCL can be either a 95, 97.5, or 99 percent UCL of the sample mean.

## G1.0 INTRODUCTION

This appendix summarizes the methods used for calculating descriptive statistics and **exposure point concentrations (EPC)** and for conducting background screening of soil and groundwater in support of the human health risk assessment (HHRA) and screening-level ecological risk assessment (SLERA) for Installation Restoration (IR) Site 34 at Alameda Point, Alameda, California.

Details of the HHRA and SLERA and presentation of the statistical results for the EPC calculations are provided in Appendices H and I to the IR Site 34 Remedial Investigation (RI) Report. Background screening results are provided in Table 4-2 in the IR Site 34 RI Report. Soil calculations were conducted for two depth intervals: 0 to 2 feet below ground surface [bgs], and 0 to 4 feet bgs. The approach and calculations described in this appendix follow U.S. Environmental Protection Agency (EPA) and U.S. Department of the Navy guidance (EPA 2000, 2002b, 2006, 2007a, 2007b; Navy 1998, 1999, 2002).

Section G2.0 describes the approach used for calculating descriptive statistics and EPCs, and Section G3.0 describes the approach for screening site soil and groundwater against background concentrations of metals. The Glossary of Terms before this introduction defines terms that are presented in **bold text** when they are first mentioned in the appendix. References are provided in Section G4.0, and figures and tables may be found immediately after the references.

## G2.0 CALCULATION OF DESCRIPTIVE STATISTICS AND EXPOSURE POINT CONCENTRATIONS

Initial selection of an approach for calculating descriptive statistics and EPCs was based on the relative sample size, detection frequency, and determination of the best-fit model for describing the underlying distribution of analytical results for each chemical, as shown on Figure G-1. Calculations were only performed for chemicals with a least one detected result. The EPC defaulted to the maximum detected concentration for chemicals with less than four detected results. Quality control field duplicate samples were treated following the approach described in the RI Work Plan (SulTech 2006). Censored measurements that exceeded the maximum detected concentration for each chemical were excluded from all analyses.

The approach used for calculating EPCs for chemicals with all detected results followed EPA (2002b) and recommendations provided in EPA's ProUCL 4 Technical and User Guides (EPA 2007a, 2007b). For chemicals with one or more nondetect results, the approach followed EPA's research on censored data methods (EPA 2006), as well as the updated recommendations provided in the ProUCL 4 software package (EPA 2007a, 2007b).

Section G2.1 provides details of the approach used for detected results only, and Section G2.2 describes the approach used for chemicals with both detected and censored results. Details of the approach used for distribution testing are provided in Section G2.3.

## G2.1

## CALCULATIONS FOR SAMPLES WITH DETECTED RESULTS ONLY

Summary statistics and EPCs for chemicals with detected results only were calculated following EPA (2002b) and recommendations in the ProUCL 4 Technical and User Guides (EPA 2007a, 2007b). Recommendations in ProUCL 4 are based on the results of simulation experiments conducted to determine the relative coverage probabilities (that is, likelihood that the true mean is bounded by the **upper confidence limit of the mean [UCL]**) for different mathematical models used to calculate a one-sided UCL of the mean (EPA 1997, 2002a; Singh and Nocerino 2002). In this approach, each method is applied to a series of synthetic data sets drawn from different known theoretical distributions or mixtures of distributions. Both the skewness of the underlying distributions for the parent data sets and the size of the samples drawn from each data set are manipulated as part of the experimental design. An optimal method for calculating a UCL is selected based on the overall performance of each analytical method over the range of conditions evaluated. ProUCL implements a series of decision rules to select an optimal method based on three sample properties: (1) best-fit distribution, (2) relative degree of skewness, and (3) relative sample size.

The ProUCL approach depends heavily on estimating the underlying distribution of a sample. An important update incorporated in ProUCL Version 3 is the inclusion of models to calculate a UCL based on the gamma distribution. EPA (1997) reported that UCLs calculated for data following a lognormal distribution using Land's method (EPA 1992; Gilbert 1987; Land 1975) are often inappropriately high for use in risk assessments. Other investigators have also studied alternative methods for calculating the UCL when data are skewed (Chen 1995; Schultz and Griffin 1999). EPA (2002a, 2007a, 2007b) suggests that UCL calculations based on a gamma model are more appropriate for skewed distributions that can be fit to either a gamma or lognormal model. Details of the approach used for testing the underlying distribution of analytical results for each chemical are provided in Section G2.3.

The optimal method for estimating an EPC was selected based on the recommendations provided in EPA (2007a,b), as shown on Figure G-1. Tables G-1, G-2, and G-3 provide detailed decision rules for selecting a method for calculating an appropriate UCL to represent the EPC. After a chemical-by-chemical evaluation of the sample size, underlying distribution, and degree of skewness, a UCL was calculated based on one of the parametric or nonparametric methods listed below (all methods from EPA [2007a, 2007b]).

### Parametric Methods

- Student's *t* UCL
- Approximate gamma UCL
- Adjusted gamma UCL
- Land's H-Statistic UCL
- Minimum variance unbiased estimate (MVUE)
- Chebyshev UCL

### Nonparametric Methods

- Nonparametric Chebyshev UCL
- Bootstrap *t* UCL
- Hall's bootstrap UCL

UCLs can be based on a one-sided 95, 97.5, or 99 percent UCL for EPCs calculated using the MVUE and nonparametric Chebyshev methods following EPA (2007a, 2007b). EPCs calculated using Student's *t* statistic or bootstrap approaches were based on a one-sided 95 percent UCL. The maximum detected concentration was used as the EPC for chemicals with fewer than four samples. The maximum detected concentration was also the default EPC when a particular estimate calculated using one of the methods described above exceeded the maximum detected concentration.

The following equations were used to calculate the mean, **standard deviations**, and UCL for the methods listed above. All terms in the equations below are defined on first use only. When the definition of a term is equation-specific, separate definitions are provided under each equation.

#### Equation 1 – Arithmetic Mean

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

where

$\bar{x}$	=	Sample arithmetic mean
$n$	=	Sample size
$x_i$	=	$i^{\text{th}}$ measurement in the sample

#### Equation 2 – Sample Standard Deviation

$$s = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$$

where

$s$	=	Sample standard deviation
-----	---	---------------------------

#### Equation 3 – MVUE for the Lognormal Mean

$$\hat{\mu} = [e(\bar{y})] \psi_n \left( \frac{s_y^2}{2} \right)$$

where

$\hat{\mu}$	=	MVUE for the lognormal mean
$e$	=	Euler's constant
$\bar{y}$	=	Mean of the natural logarithms of the sample data
$s_y^2$	=	Variance of the natural logarithms of the sample data
$\psi_n(t)$	=	Infinite series, calculated as follows:

$$\psi_n(t) = 1 + \frac{(n-1)t}{n} + \frac{(n-1)^3 t^2}{2! n^2 (n+1)} + \frac{(n-1)^5 t^3}{3! n^3 (n+1)(n+3)} + \frac{(n-1)^7 t^4}{4! n^4 (n+1)(n+3)(n+5)} + \dots$$

$$\text{where } t = \frac{s_y^2}{2}$$

**Equation 4 – MVUE for the Standard Deviation of the Lognormal Mean**

$$s = \sqrt{e^{(2\bar{y})} \left\{ \psi_n(2s_y^2) - \psi_n \left[ \frac{s_y^2 (n-2)}{n-1} \right] \right\}}$$

where

$$s(\hat{\mu}) = \text{MVUE for the standard deviation of the lognormal mean}$$

**Equation 5 – UCL Calculated Using Student's *t* Statistic Method**

$$UCL_{1-\alpha} = \bar{x} + t_{1-\alpha, n-1} \frac{s}{\sqrt{n}}$$

where

- $UCL_{1-\alpha}$  = 1- $\alpha$  UCL calculated using Student's *t* statistic
- $\alpha$  = Type I error rate
- $t_{1-\alpha, n-1}$  = 1- $\alpha$  quantile of Student's *t* distribution with n-1 degrees of freedom

**Equation 6 – UCL Calculated Using Land's H-Statistic Method**

$$UCL_{1-\alpha} = e \left( \bar{y} + 0.5s_y^2 + \frac{s_y H_{1-\alpha}}{\sqrt{n-1}} \right)$$

where

- $UCL_{1-\alpha}$  = 1- $\alpha$  UCL calculated using Land's H-statistic
- $s_y$  = Standard deviation of the natural logarithms of the sample data
- H = Land's H-statistic obtained from published tables (Land 1975)

**Equation 7 – UCL Calculated Using Nonparametric Chebyshev Method**

$$UCL_{1-\alpha} = \bar{x} + \sqrt{\frac{1}{\alpha} - 1} \left( \frac{s}{\sqrt{n}} \right)$$

where

- $UCL_{1-\alpha}$  = 1- $\alpha$  UCL calculated using the nonparametric Chebyshev method

**Equation 8 – UCL Calculated Using MVUE Chebyshev Method**

$$UCL_{1-\alpha} = \bar{y} + \sqrt{\left(\frac{1}{\alpha} - 1\right) s^2(\hat{\mu})}$$

where

$UCL_{1-\alpha}$  = 1- $\alpha$  UCL calculated using the MVUE Chebyshev method

**Equation 9 – UCL Calculated Using Approximate Gamma Method**

$$UCL_{1-\alpha} = \frac{2n\hat{k}^*\bar{x}}{\chi_{2n\hat{k}^*}^2(\alpha)}$$

where

$UCL_{1-\alpha}$  = 1- $\alpha$  UCL calculated using the approximate gamma method  
 $\hat{k}^*$  = Bias-corrected maximum likelihood estimate (MLE) of the shape parameter for a gamma distribution, calculated as

$$\hat{k}^* = \frac{(n-3)\hat{k}}{n} + \frac{2}{n}$$

where

$\hat{k}$  = MLE of the shape parameter  
 $\chi_{2n\hat{k}^*}^2$  = Quantile of the Chi-square distribution with  $2n\hat{k}^*$  degrees of freedom

**Equation 10 – UCL Calculated Using Adjusted Gamma Method**

$$UCL_{1-\alpha} = \frac{2n\hat{k}^*\bar{x}}{\chi_{2n\hat{k}^*}^2(\beta)}, \text{ where}$$

$UCL_{1-\alpha}$  = 1- $\alpha$  UCL calculated using the adjusted gamma method  
 $\beta$  = Adjusted value of  $\alpha$ , the Type I error rate, from the table provided in Grice and Bain (1980) and reproduced in EPA (2007a)

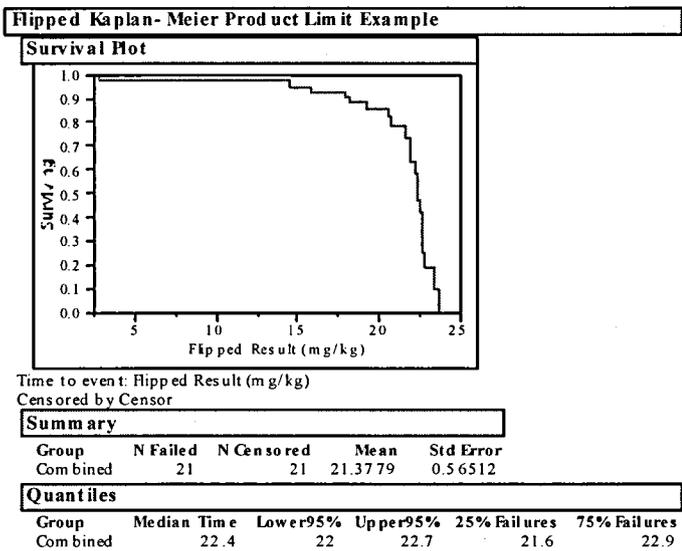

**G2.2 CALCULATIONS FOR SAMPLES WITH DETECTED AND CENSORED RESULTS**

A number of proposals have appeared in both the guidance and scientific literature for calculating a UCL of the mean when data are left censored (Helsel and Cohn 1988; Schultz and Griffin 1999; Helsel 1990, 2005a, 2005b; Ginevan and Splitstone 2002; EPA 2002b). EPA (2006) provides results of extensive Monte Carlo experiments conducted to determine the optimal model for calculating a UCL based on the relative sample size, underlying distribution (degree of skewness), and frequency of censored measurements. The recommendations provided in EPA (2006) have been incorporated in the ProUCL 4 software package (2007a, 2007b).

For IR Site 34 at Alameda, recommendations in EPA (2006, 2007a, 2007b) were followed for calculating UCLs for all chemicals with one or more censored results. The decision rules followed for selecting methods based on sample size, degree of skewness, and frequency of censorship are provided in Tables G-1, G-2, and G-3. The algorithms and numerical models used for these calculations are described in EPA (2006, 2007a) and Helsel (2005a).

All of the recommended censored UCL methods in EPA (2006) are based on the nonparametric Kaplan-Meier (K-M) product limit estimator. The K-M approach employs a well-studied method that has been used in the field of causal analysis for more than 40 years (Kaplan and Meier 1958). The K-M model is still widely used today in medical research for calculating survivorship in clinical studies and is a principal tool for conducting failure analysis in many industrial fields (Meeker and Escobar 1998). Helsel (2005a, 2005b) has proposed using a modification of the K-M estimator for treating samples with **left-censored** data. Helsel's proposed approach, termed the "flipped K-M model," uses a simple technique (subtraction of each measurement from a constant that is greater than the largest measurement) to convert left-censored data to right-censored data before the K-M model is run. Because the K-M model is a well-studied and proven technique for working with censored data, it is incorporated in most commercial statistical software packages that have platforms for calculating survival curves or for conducting failure analysis. Flipping the data is required for the analysis using software designed for right-censored data.

The K-M estimator is an empirical, nonparametric procedure that can be applied to data with multiple censoring limits (reporting or detection limits in environmental applications). Details of the underlying mathematics of the K-M model are available from a number of sources (Kaplan and Meier 1958; Meeker and Escobar 1998; Klein and Moeschberger 2003; Lee and Wang 2003). K-M results are typically presented graphically in the form of a survival curve (or conversely, as a failure curve). Survival curves generated using the K-M model follow a staircase pattern, as shown below in the example output from a popular commercial software package (JMP from SAS Institute).

All of the recommended censored UCL methods in EPA (2006, 2007a, 2007b) use the K-M approach to calculate the sample mean. The UCL of the mean is then calculated using one of the following four methods: (1) Student's *t* cutoff, (2) nonparametric Chebyshev method, (3) percentile bootstrap, or (4) bias-corrected accelerated (BCa) bootstrap. Additional details for each of these methods are provided in EPA (2006, 2007a, 2007b). It should be noted that the approach employing the K-M model and nonparametric Chebyshev method is used to calculate either a 95, 97.5, or 99 percent UCL, depending on the sample size and degree of skewness in the data (see Tables G-1, G-2, and G-3).

### G2.3 DISTRIBUTION TESTING

Both graphical methods and statistical goodness-of-fit (GOF) tests were used to assign a best-fit distribution for each chemical. Graphical methods included the preparation of **quantile** probability plots, outlier box plots, and frequency histograms for four potential fits: normal, lognormal, gamma, and nonparametric.

Distribution testing was only conducted for chemicals with at least eight detected results. Statistical GOF tests were conducted using the detected data only, although graphical presentations of the combined detected and censored results were also evaluated as an additional aid for assigning a best-fit distribution.

Formal tests were conducted using two well-established GOF tests: the Shapiro-Wilk *W* test (for normal and lognormal distributions) and the Cramer von Mises *W*<sup>2</sup> test (for gamma distributions). Figure G-3 provides examples of the graphical plots and presentation of the GOF test results used to evaluate the distribution of each data set. The statistical GOF tests are described below.

The Shapiro-Wilk W test is one of the most powerful GOF tests for evaluating whether a set of measurements follows a normal or lognormal distribution. The test relies on computing a correlation between the quantiles of the standard normal distribution and the ordered values of the observed data. When the Shapiro-Wilk W statistic is close to 1.0, the observed data will follow an essentially straight line when they are displayed using a normal probability plot. The following null ( $H_0$ ) and alternative ( $H_A$ ) hypotheses were tested using the Shapiro-Wilk W test:

$H_0$ : The data follow a normal distribution.

$H_A$ : The data do not follow a normal distribution.

Tests are conducted sequentially on data in original and natural-log transformed units. A **Type I error rate** ( $\alpha$ ) of 0.05 (equivalent to 5 percent) was used to interpret the significance of each test. A Type I error rate of 0.05 means there is a 5 percent chance that the  $H_0$  will be rejected when it is true (that is, the data are normally distributed), leading to the false conclusion that the underlying distribution is not normal. When the test is conducted using log-transformed data, failure to reject the  $H_0$  leads to the conclusion that the data follow a lognormal distribution. (Rejection of  $H_0$  indicates that the data are not lognormally distributed.)

The Cramer von Mises  $W^2$  test belongs to the quadratic class of **empirical distribution function (EDF)** statistics and is based on evaluating the squared difference between the EDF and the proposed **cumulative distribution function (CDF)**. The test statistic evaluated for the Cramer von Mises test is the  $W^2$ . When the probability of calculating a  $W^2$  greater than that shown for the observed data is less than some nominal probability (that is, 0.05), then the  $H_0$  that the data follow a gamma distribution is rejected. If the test fails to reject  $H_0$ , then it is concluded that the data follow a gamma distribution.

Final determination of the best-fit distribution was made using the results of the statistical GOF tests, as well as through examination of probability plots, outlier box plots, and frequency histograms. Best professional judgment was required to make the final determination because the power of the GOF tests is strongly affected by sample size, as well as the presence of outliers and censored measurements. Additional decision criteria were applied in cases where GOF testing indicated that a chemical followed more than one distribution. A normal distribution was selected by default in cases where the data could be fit to a normal, lognormal, or gamma distribution. If the data were not normal and could be fit to either a lognormal or gamma distribution, then the best-fit distribution was selected based on further examination of the quantile probability plots for each distribution. In this case, two criteria were evaluated in selecting the best-fit distribution: the number of measurements that depart from the linear fit of the observed data to the theoretical quantiles, and the magnitude of departure of each measurement from the linear fit. The distribution with the fewest number and smallest magnitude of departure from the fitted line in the quantile probability plots was selected as the best-fit distribution.

### G3.0 BACKGROUND SCREENING PROCESS FOR METALS IN SOIL AND GROUNDWATER

Two-population statistical tests were used to compare metal concentrations in soil and groundwater at IR Site 34 with background data sets developed for Alameda Point (PRC Environmental Management, Inc. [PRC] 1997). All methods followed Navy and EPA statistical guidance for evaluating background concentrations of chemicals in soil (Navy 1998, 1999, 2002; EPA 2002b). Results of the statistical comparison of metals concentrations in IR Site 34 soil with background are provided in (Table 4-2). Details of the background screening approach are summarized on Figure G-3 and described below.

As shown on Figure G-3, a tiered approach employing one or more statistical methods was used to conduct two-population tests. The first tier in this approach compares the median concentrations between the site and background populations using either the Wilcoxon rank sum (WRS) test, Gehan's modification to the WRS test (WRS[G]), randomization (RAN) test, or test of proportions. Selection of the specific tests depends on the relative detection frequency and sample size of each of the populations being compared. A second tier of testing is contingent on the results of the first tier tests. Second tier testing is designed to compare the right-hand tails or upper quantiles of the site and background populations using the quantile test. One-sided statistical tests are used in all cases and employ a Type I error rate of 0.05 (5 percent).

**WRS and WRS(G) tests:** Testing was performed using either the nonparametric WRS or WRS(G) test (Navy 1999, 2002) for metals with at least 60 percent detected data and at least 10 measurements in both the site and background populations.

The following  $H_0$  and  $H_A$  hypotheses were tested:

- $H_0$ : the median metal concentration for the site is less than or equal to the median concentration in the background population
- $H_A$ : the median metal concentration for the site is greater than the median concentration in the background population

The WRS test was used for samples with a single detection limit, and the WRS(G) test was used for samples with multiple detection limits, as described in Navy (1999, 2002). All censored measurements were set to a concentration slightly below the minimum detected concentration (that is, censored measurements were tied at a rank of 1) for the WRS test. The reporting limit was substituted for all censored data analyzed using the WRS(G) test. The WRS[G] test makes specific adjustments in the calculation of the rank scores to account for data with multiple detection limits. A RAN test of the medians was performed instead of the WRS or WRS(G) test for cases where either the site or background population contained fewer than 10 measurements. Details of the approach for implementing a RAN test of the median concentrations are provided in numerous technical sources on resampling (Noreen 1989; Todman 2001; Edgington 1995).

Two additional tests, the test of proportions and the quantile test, were performed in cases where the detection frequency in the site or background population was less than 60 percent. The quantile test was also performed in cases where the WRS, WRS(G), or RAN tests concluded that the site median concentration did not exceed the background median concentration (see Figure G-3). Each of these tests is described below.

**Test of Proportions:** The detection frequencies in the site and background populations were compared using the test of proportions for metals with fewer than 60 percent detected data. The test of proportions used a contingency table approach, and the significance of the test was determined using the Fisher exact test. (Note that Navy [1999, 2002] describe an approach for conducting the test of proportions using a normal approximation to the binomial distribution, which can also be used if software is not available for implementing the Fisher exact test.) Details on the Fisher exact test can be found in standard textbooks on statistics, such as Zar (1996).

The following  $H_0$  and  $H_A$  hypotheses were tested using the test of proportions:

- $H_0$ : the proportion of detected measurements greater than C at the site is less than or equal to the proportion of measurements greater than C in the background population
- $H_A$ : the proportion of detected measurements greater than C at the site is greater than the proportion of measurements greater than C in the background population

In the  $H_0$  and  $H_A$  statements above, C is defined as a concentration that is slightly larger than the maximum censored datum in the background data set.

**Quantile Test:** The quantile test (Johnson and others 1987; EPA 1994, 2000, 2002b, 2007a, 2007b; Navy 1998, 1999, 2002) was conducted for all metals with less than 60 percent detected data and for all cases where either the WRS, WRS(G), or RAN test did not reject  $H_0$ ; that is, when it was concluded that the median site and background concentrations were not significantly different.

The quantile test is a nonparametric two-population test developed for comparing the right-hand tails or upper quantiles of two distributions. The quantile test can be used when some proportion of high-value measurements (rather than the entire distribution) of one population has shifted relative to a second population. The quantile test is not as powerful as the WRS test when the distribution of site concentrations is shifted in its entirety to the right of the background distribution. However, the quantile test is more powerful than the WRS test for detecting cases where only a small number of high-value measurements are present in the upper quantile of the site distribution. For this reason, EPA and Navy guidance recommends that the quantile test be used in conjunction with the WRS test (EPA 1994, 2002b, 2007a, 2007b; Navy 1999, 2002). When applied together, these tests have more power to detect true differences between two population distributions.

The quantile test is easy to apply and consists of looking at the largest  $r$  measurements in the pooled (and ordered) site and background data sets and counting the number of  $r$  measurements that are from the site. If  $k$  or more of the  $r$  measurements are site measurements, the quantile test declares that the upper range of concentrations at the site is elevated relative to the background population. The  $H_0$  addressed by the quantile test is that  $\varepsilon \leq 0$  and  $\Delta/\sigma \leq 0$ , where  $\varepsilon$  is the proportion of site measurements that have shifted to the right and  $\Delta/\sigma$  is the magnitude (in units of standard deviation,  $\sigma$ ) of the shift.

It should be noted that the guidance for conducting the quantile test seems to present several alternatives for the treatment of nondetect or censored values when tabulating  $k$  and  $r$ . For example, EPA (1994) states that “if measurements less than the limit of detection are present in either data set, assume their value is less than the  $r^{\text{th}}$  largest measured value in the combined data set of  $N$  measurements.” This effectively ignores censored measurements, and allows conduct of the test as long as at least  $r$  detected measurements are present in the combined site and background data set. This is the approach that was used for conducting site versus background comparisons for Site 34 soil in the draft RI. The Navy’s soil background guidance (Navy 2002) states that “test may be inconclusive if less-than values are present among the largest  $r$  data values” and provides an additional note stating “ignore any less-than values when determining the largest detected  $r$  measurements.” However, release 4 of EPA’s ProUCL software package (EPA 2007a, 2007b) now includes a platform for conducting the quantile test, and takes a more conservative position with regard to the handling of nondetects. That is, ProUCL 4 takes the position that the presence of nondetects among the largest  $r$  detected measurements compromises the validity of the test, and issues a warning that the test cannot be conducted when this occurs. ProUCL 4 was released after the soil background comparisons were conducted for Site 34, but was available at the time the groundwater comparisons were being conducted. The procedure for treating nondetects from ProUCL 4 was used for conducting site versus background comparisons for Site 34 groundwater. This decision was made because ProUCL has been released as a tool for use with several EPA statistical guidance documents, and there was interest in providing test results for the quantile test that could be reproduced independently by the regulatory agencies and other reviewers.

EPA and Navy guidance provide critical values for the quantile test (EPA 1994, 2000; Navy 1999, 2002). The critical probabilities were derived using Monte Carlo simulation for cases where the sample sizes for the site or background populations exceeded the range of values provided in these tables (that is, either the site or background sample size exceeded 100) or the paired values for the site and background population did not exactly match the tabulated values. The stochastic model developed for calculating critical values of the quantile test was validated by successfully reproducing the published critical values for site and background population sizes in the range of 5 to 100.

Again, it should be noted that the WRS (or WRS[G] or RAN) test, the quantile test, and the test of proportions are applied sequentially. The quantile test and the test of proportions are also conditional tests in this scheme (see Figure G-3). That is, if  $H_0$  (site median concentration is less than or equal to background) is rejected under the WRS (or WRS[G] or RAN) test, then no further testing is necessary and the chemical is treated as a chemical of potential concern

(COPC). Failure to reject  $H_0$  triggers implementation of the quantile test. In cases where the detection frequency is less than 60 percent, both the test of proportions and quantile test are applied. Independent conclusions are reported for both the quantile test and the test of proportions, so rejection of  $H_0$  for either test can result in a conclusion that the site population exceeds background. However, in cases where the only difference between the site and background populations is based on the test of proportions, site-specific information and professional judgment are used in a weight-of-evidence process to ultimately determine whether treating a chemical as a COPC was justified. A qualifier is entered in the background screening tables and a footnote is used to indicate that caution should be exercised in cases where a chemical is determined to exceed background based only on a comparison of detection frequencies. Conclusions for the background screen are listed as "EQUIVOCAL" in the summary tables for all cases where both the WRS (or WRS[G]) and quantile tests could not be applied, and where the test of proportions indicated no significant difference between the detection frequencies. In these cases, professional judgment and examination of outlier box plots and the range of detected measurements were used to determine if a chemical should be treated as a COPC.

**TABLE G-3: EPA RECOMMENDATIONS FOR CALCULATING A UCL FOR NONPARAMETRIC DISTRIBUTIONS**

Remedial Investigation Report for Installation Restoration Site 34, Alameda Point, Alameda, California

<b>Part A – All Results Detected (EPA 2007a, 2007b)</b>		
$\hat{\sigma}$	n	Recommended Method
$\hat{\sigma} \leq 0.50$	All n	UCL <sub>95</sub> , Student's <i>t</i>
$0.50 < \hat{\sigma} \leq 1.0$	All n	UCL <sub>95</sub> , Chebyshev (nonparametric)
$1.0 < \hat{\sigma} \leq 2.0$	n < 50	UCL <sub>99</sub> , Chebyshev (nonparametric)
	n ≥ 50	UCL <sub>97.5</sub> , Chebyshev (nonparametric)
$2.0 < \hat{\sigma} \leq 3.0$	n < 10	Hall's Bootstrap (or UCL <sub>99</sub> , Chebyshev [nonparametric])
	n ≥ 10	UCL <sub>99</sub> , Chebyshev (nonparametric)
$3.0 < \hat{\sigma} \leq 3.5$	n < 30	Hall's Bootstrap (or UCL <sub>99</sub> , Chebyshev [nonparametric])
	n ≥ 30	UCL <sub>99</sub> , Chebyshev (nonparametric)
$\hat{\sigma} > 3.5$	n < 100	Hall's Bootstrap (or UCL <sub>99</sub> , Chebyshev [nonparametric])
	n ≥ 100	UCL <sub>99</sub> , Chebyshev (nonparametric)

**Part B – Detected and Censored Results (EPA 2006, 2007a, 2007b)**

Follow recommendations for lognormal distributions in Table G-2 (Part B), with the following exception:  
For  $\hat{\sigma} < 0.50$  and fewer than 8 detected measurements use UCL<sub>95</sub>, KM (Student's *t* cutoff)

Notes:

- > Greater than
- ≥ Greater than or equal to
- < Less than
- ≤ Less than or equal to
- $\hat{\sigma}$  Standard deviation of the natural logarithms of the data
- EPA U.S. Environmental Protection Agency
- UCL One-sided upper confidence limit of the mean

## ***LIST OF TABLES***

---

### **Selection of Exposure Pathways**

H-1 EPA RAGS Part D Table 1, Selection of Exposure Pathways, Commercial/Industrial Workers, Construction Workers, Residents, and Recreational Users

### **Occurrence, Distribution, and Selection of COPCs**

H-2.1 EPA RAGS Part D Table 2, Occurrence, Distribution, and Selection of Chemicals of Potential Concern, Surface Soil (0 to 2 feet bgs)

H-2.2 EPA RAGS Part D Table 2, Occurrence, Distribution, and Selection of Chemicals of Potential Concern, Surface and Subsurface Soil (0 to 4 feet bgs)

H-2.3 EPA RAGS Part D Table 2, Occurrence, Distribution, and Selection of Chemicals of Potential Concern, Groundwater

### **Exposure Point Concentration Summaries**

H-3.1 EPA RAGS Part D Table 3, Exposure Point Concentration Summary, Surface Soil (0 to 2 feet bgs)

H-3.2 EPA RAGS Part D Table 3, Exposure Point Concentration Summary, Method 1, Surface and Subsurface Soil (0 to 4 feet bgs)

H-3.3 EPA RAGS Part D Table 3, Exposure Point Concentration Summary, Groundwater

H-3.4 Exposure Point Concentration Summary, Ambient Air Concentrations via Volatilization in Surface Soil (0 to 2 feet bgs)

H-3.5 Exposure Point Concentration Summary, Ambient Air Concentrations via Volatilization in Surface and Subsurface Soil (0 to 4 feet bgs)

H-3.6 Exposure Point Concentration Summary, Ambient Air Concentrations via Volatilization in Groundwater

### **Values Used for Daily Intake**

H-4.1 EPA RAGS Part D Table 4, Values Used for Daily Intake, RME Soil Exposures

H-4.2 EPA RAGS Part D Table 4, Values Used for Daily Intake, RME Groundwater Exposures

H-4.3 EPA RAGS Part D Table 4, Values Used for Daily Intake, CTE Soil Exposures

H-4.4 EPA RAGS Part D Table 4, Values Used for Daily Intake, CTE Groundwater Exposures

### **Chemical-Specific Factors**

H-5.1 Dermal Absorption Factors

H-5.2 Chemical Data and Uptake Factors for Ingestion of Homegrown Produce Pathway

## **LIST OF TABLE (Continued)**

---

### **Toxicity Data**

#### **METHOD 1**

- H-6.1 EPA RAGS Part D Table 6.1, Noncancer Toxicity Data – Oral/Dermal, Method 1 Values (EPA Sources)
- H-6.2 EPA RAGS Part D Table 6.2, Noncancer Toxicity Data – Inhalation, Method 1 Values (EPA Sources)
- H-6.3 EPA RAGS Part D Table 6.3, Cancer Toxicity Data – Oral/Dermal, Method 1 Values (EPA Sources)
- H-6.4 EPA RAGS Part D Table 6.4, Cancer Toxicity Data – Inhalation, Method 1 Values (EPA Sources)

#### **METHOD 2**

- H-6.5 EPA RAGS Part D Table 6.5, Noncancer Toxicity Data – Oral/Dermal, Method 2 Values (DTSC-Preferred Sources)
- H-6.6 EPA RAGS Part D Table 6.6, Noncancer Toxicity Data – Inhalation, Method 2 Values (DTSC-Preferred Sources)
- H-6.7 EPA RAGS Part D Table 6.7, Cancer Toxicity Data – Oral/Dermal, Method 2 Values (DTSC-Preferred Sources)
- H-6.8 EPA RAGS Part D Table 6.8, Cancer Toxicity Data – Inhalation, Method 2 Values (DTSC-Preferred Sources)

### **RME Cancer Risks and Noncancer Hazards**

#### **METHOD 1**

- H-7.1 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Commercial/Industrial Worker, Surface Soil (0 to 2 feet bgs)
- H-7.2 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Commercial/Industrial Worker, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-7.3 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Construction Worker, Surface Soil (0 to 2 feet bgs)
- H-7.4 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Construction Worker, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-7.5 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Adult Resident, Surface Soil (0 to 2 feet bgs)
- H-7.6 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Adult Resident, Surface and Subsurface Soil (0 to 4 feet bgs)

## ***LIST OF TABLE (Continued)***

---

- H-7.7 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Child Resident, Surface Soil (0 to 2 feet bgs)
- H-7.8 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Child Resident, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-7.9 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Child + Adult Resident, Surface Soil (0 to 2 feet bgs)
- H-7.10 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Child + Adult Resident, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-7.11 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Recreational Adult, Surface Soil (0 to 2 feet bgs)
- H-7.12 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Recreational Child, Surface Soil (0 to 2 feet bgs)
- H-7.13 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from EPA Sources (Method 1), Recreational Child + Adult, Surface Soil (0 to 2 feet bgs)

### **METHOD 2**

- H-7.14 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Commercial/Industrial Worker, Surface Soil (0 to 2 feet bgs)
- H-7.15 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Commercial/Industrial Worker, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-7.16 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Construction Worker, Surface Soil (0 to 2 feet bgs)
- H-7.17 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Construction Worker, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-7.18 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Adult Resident, Surface Soil (0 to 2 feet bgs)
- H-7.19 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Adult Resident, Surface and Subsurface Soil (0 to 4 feet bgs)

## **LIST OF TABLE (Continued)**

---

- H-7.20 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Child Resident, Surface Soil (0 to 2 feet bgs)
- H-7.21 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Child Resident, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-7.22 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Child + Adult Resident, Surface Soil (0 to 2 feet bgs)
- H-7.23 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Child + Adult Resident, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-7.24 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Recreational Adult, Surface Soil (0 to 2 feet bgs)
- H-7.25 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Recreational Child, Surface Soil (0 to 2 feet bgs)
- H-7.26 EPA RAGS Part D Table 7a-b, Calculation of RME Cancer Risks and Noncancer Hazards Using Toxicity Data from DTSC-Preferred Sources (Method 2), Recreational Child + Adult, Surface Soil (0 to 2 feet bgs)

### **Summaries of RME Receptor Risks and Hazards for COPCs**

#### **METHOD 1**

- H-8.1 EPA RAGS Part D Table 9, Summary of RME Receptor Risk and Hazards for COPCs Using Toxicity Data from EPA Sources (Method 1), Commercial/Industrial Worker, Surface Soil (0 to 2 feet bgs)
- H-8.2 EPA RAGS Part D Table 9, Summary of RME Receptor Risk and Hazards for COPCs Using Toxicity Data from EPA Sources (Method 1), Commercial/Industrial Worker, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-8.3 EPA RAGS Part D Table 9, Summary of RME Receptor Risk and Hazards for COPCs Using Toxicity Data from EPA Sources (Method 1), Construction Worker, Surface Soil (0 to 2 feet bgs)
- H-8.4 EPA RAGS Part D Table 9, Summary of RME Receptor Risk and Hazards for COPCs Using Toxicity Data from EPA Sources (Method 1), Construction Worker, Surface and Subsurface Soil (0 to 4 feet bgs)
- H-8.5 EPA RAGS Part D Table 9, Summary of RME Receptor Risk and Hazards for COPCs Using Toxicity Data from EPA Sources (Method 1), Adult Resident, Surface Soil (0 to 2 feet bgs)
- H-8.6 EPA RAGS Part D Table 9, Summary of RME Receptor Risk and Hazards for COPCs Using Toxicity Data from EPA Sources (Method 1), Adult Resident, Surface and Subsurface Soil (0 to 4 feet bgs)

## ***LIST OF TABLE (Continued)***

---

- H-8.7 EPA RAGS Part D Table 9, Summary of RME Receptor Risk and Hazards for COPCs Using Toxicity Data from EPA Sources (Method 1), Child Resident, Surface Soil (0 to 2 feet bgs)
- H-8.8 EPA RAGS Part D Table 9, Summary of RME Receptor Risk and Hazards for COPCs Using Toxicity Data from EPA Sources (Method 1), Child Resident, Surface and Subsurface Soil (0 to 4 feet bgs)

**Lead Risk Assessment Results Using LeadSpread**

- H-10.1 Lead Risk Assessment Results Using LeadSpread, Residents, Surface Soil (0 to 4 feet bgs)
- H-10.2 Lead Risk Assessment Results Using LeadSpread, Residents, Surface and Subsurface Soil (0 to 4 feet bgs)

## ACRONYMS AND ABBREVIATIONS

---

$\mu\text{g/dL}$	Microgram per deciliter
$\mu\text{g/m}^3$	Microgram per cubic meter
95UCL	95 percent upper confidence limit of the mean
97.5UCL	97.5 percent upper confidence limit of the mean
99UCL	99 percent upper confidence limit of the mean
ABS	Dermal absorption fraction
AST	Aboveground storage tank
$\text{atm}\cdot\text{m}^3/\text{mol}$	Atmosphere-cubic meter per mole
bgs	Below ground surface
Cal/EPA	California Environmental Protection Agency
$\text{cm}^2$	Square centimeter
COPC	Chemical of potential concern
CSM	Conceptual site model
CTE	Central tendency exposure
dP	Pressure differences
DTSC	Department of Toxic Substances Control
EBS	Environmental Baseline Survey
EFH	Exposure Factors Handbook
EPA	U.S. Environmental Protection Agency
EPC	Exposure point concentration
$F_{oc}$	Fraction of organic carbon
$\text{g/cm}\cdot\text{s}^2$	Gram per centimeter per square second
$\text{g/day}$	Gram per day
$\text{g/kg}\cdot\text{day}$	Gram per kilogram per day
GAP	Generator Accumulation Point
GOF	Goodness-of-fit
HEAST	Health Effects Assessment Summary Tables
HHRA	Human Health Risk Assessment
HI	Hazard index
HQ	Hazard quotient
IR	Installation Restoration
IRIS	Integrated Risk Information System

## **ACRONYMS AND ABBREVIATIONS (Continued)**

---

K <sub>oc</sub>	Organic carbon-water partition coefficient
K <sub>ow</sub>	Octanol-water partition coefficient
L/min	Liter per minute
LOAEL	Lowest observed adverse effect level
m <sup>3</sup> /day	Cubic meter per day
m <sup>3</sup> /hr	Cubic meter per hour
mg/cm <sup>2</sup>	Milligram per square centimeter
mg/day	Milligram per day
mg/kg	Milligram per kilogram
NARF	Naval Air Rework Facility
NAS	Naval Air Station
NCP	National Oil and Hazardous Substances Pollution Contingency Plan
NOAEL	No observed adverse effect level
OEHHA	Office of Environmental Health Hazard Assessment
PAH	Polycyclic aromatic hydrocarbon
PCB	Polychlorinated biphenyl
PEF	Particulate emission factor
PPRTV	Provisional Peer-Reviewed Toxicity Values
PRG	Preliminary remediation goal
RAGS	Risk Assessment Guidance for Superfund
REL	Reference exposure level
RfC	Reference concentration
RfD	Reference dose
RI	Remedial Investigation
RME	Reasonable maximum exposure
SF	Slope factor
SI	Site Inspection
SVOC	Semivolatile organic compound
VF	Volatilization factor
VOC	Volatile organic compound

## H1.0 INTRODUCTION

This appendix presents the methods and the results of the baseline Human Health Risk Assessment (HHRA) conducted as part of the Remedial Investigation (RI) for Installation Restoration (IR) Site 34 (Site 34), at the former Naval Air Station (NAS) Alameda in Alameda, California. NAS Alameda is now known as Alameda Point. The HHRA has been prepared to help fulfill the objectives of the RI and incorporates guidance issued by the U.S. Department of the Navy, the U.S. Environmental Protection Agency (EPA), and the California Environmental Protection Agency's (Cal/EPA) Department of Toxic Substances Control (DTSC). The RI Report contains background information on the history of the facility and other operations conducted at IR Site 34, the physical characteristics of the area, the results of previous investigations conducted at IR Site 34, and the conceptual framework used to implement and document the RI.

HHRAs are prepared to evaluate potential health risks under current and potential future land use conditions. The specific objectives of this HHRA are presented below.

- Estimate the magnitude of potential human health risks associated with current site conditions and potential future land use scenarios.
- Identify the environmental media and chemicals that pose the primary health concerns.
- Identify the environmental media and chemicals that pose little or no threat to human health.
- Provide a foundation for assessing the need for further response actions.

## H2.0 SITE DESCRIPTION AND BACKGROUND

IR Site 34 is located in the north-central portion of Alameda Point, adjacent to the Oakland Inner Harbor (see Figure 1-2 of the RI Report). The boundary of IR Site 34 was identified during the 2003 Site Inspection (SI) in which site risks were identified based on the results of samples collected during the Environmental Baseline Survey (EBS) (Bechtel Environmental, Inc. 2003). IR Site 34 is a 4.18-acre area that is a partially paved, relatively flat open space. IR Site 34 was a Naval Air Rework Facility (NARF) used to maintain base equipment such as scaffolding and other apparatus. The site was used primarily for painting services, storage, wood and metal shop activities, and sandblasting activities. IR Site 34 formerly contained several structures, including 12 buildings (331, 330, 343, 475, 344, 510, 474, 477, 604, 476, 479, and 472) and intervening open areas; 7 aboveground storage tanks (AST) (330A, 330B, 344A, 344B, 344C, 344D, and 331); Generator Accumulation Points (GAP) 78 and 79; 15 transformers; and an aviation gasoline fuel line. All buildings, ASTs, GAPs, transformers, and fuel lines were removed between 1996 and 2000, except for concrete pads. Figure 1-3 of the RI Report shows the historical and existing site features at IR Site 34.

### **H3.0 RISK ASSESSMENT GUIDELINES AND TECHNICAL APPROACH**

This HHRA used methods based on the risk assessment framework developed by EPA and DTSC, as documented in “Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual (Part A), Interim Final” (EPA 1989) and “Supplemental Guidance for Human Health Multimedia Risk Assessments of Hazardous Waste Sites and Permitted Facilities” (DTSC 1992). In addition, the risk assessment approach was developed to satisfy Navy requirements as defined in the “Memorandum Regarding Conducting Human Health Risk Assessments under the Environmental Restoration Program” (Navy 2001).

A dual-tracking approach was used to consider both EPA and DTSC toxicity values. To satisfy federal (Navy and EPA) and state (DTSC) requirements, this HHRA prepared a set of risk assessment results using EPA toxicity values, referred to as Method 1, and a separate set of risk assessment results using DTSC toxicity values, referred to as Method 2. Section H6.0 discusses EPA and DTSC toxicity values.

This HHRA also calculated total risks, which include risks from background concentrations of metals, and incremental risks, which exclude risks from background concentrations of metals. Total and incremental risks were prepared using both EPA (Method 1) and DTSC toxicity values (Method 2).

### **H4.0 DATA EVALUATION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN**

The objective of data evaluation is to develop a list of chemicals of potential concern (COPC) for risk assessment purposes. COPCs are defined as the subset of chemicals at a site most likely to present a potential health risk. A limited COPC list is desirable when the list of detected chemicals (1) exceeds 80 detected chemicals as suggested in EPA’s “Risk Assessment Guidance for Superfund” (RAGS) (EPA 2001b) or (2) requires intensive modeling. However, based on agreement with the regulatory agencies, the HHRA quantitatively evaluated all chemicals detected in soil and groundwater, except for essential nutrients (calcium, magnesium, potassium, and sodium).

This section presents the methods used to evaluate data for inclusion in the risk assessment and the methods used to identify COPCs. Data were considered to be appropriate for use in the HHRA if they (1) were validated, (2) were not qualified as rejected (“R”), (3) met the data quality objectives for the RI described in the IR Site 34 RI Work Plan (SulTech 2006), and (4) reflect current site conditions. Section 1.3.4 of the RI Report provides a summary of the data collected during previous investigations and the RI sampling activities at IR Site 34. In general, the HHRA did not use field screening data, such as organic vapor readings measured with a photoionization detector or lead and chromium concentrations measured using a portable x-ray fluorescence unit. In addition, the HHRA did not use data collected to characterize potential historical releases physically present in paved structures such as sediment from drain piping or oil-water separators.

#### **H4.1 DATA VALIDATION**

As part of the data evaluation process, all analytical data were reviewed to verify that they meet EPA data quality criteria for use in risk assessment (EPA 1992). An independent validation contractor evaluated the data collected during the RI using EPA's Contract Laboratory Program National Functional Guidelines for Inorganic and Organic Data Review (EPA 1999, 2002a). As part of the data evaluation process, 90 percent of the analytical data underwent cursory validation, and 10 percent of the data underwent full validation to verify that they met EPA data quality criteria for use in risk assessment (EPA 1992). The Quality Control Summary Report presented in Appendix F provides the results of the data validation process.

Data used in this HHRA included data without qualifiers, data qualified as estimated (J), and data qualified as not detected (U). Section H5.4 describes the methods used to incorporate detection limits when estimating exposure point concentrations (EPC).

#### **H4.2 SOIL DATA**

This HHRA used soil data collected in 1995 as part of the EBS and in 2006 as part of the RI sampling activities. The HHRA excluded the volatile organic compound (VOC) data collected in 1995 because it was considered too old to be representative of current conditions and also the VOC data exceeded project-required reporting limits listed for the VOCs in the RI Work Plan (SulTech 2006). The only VOCs detected in the 1995 data were the common laboratory contaminants 2-butanone and methylene chloride at estimated concentrations. The HHRA also excluded the 1995 data for nondetected polycyclic aromatic hydrocarbon (PAH) results because the 1995 data exceeded the project-required reporting limits listed for PAHs in the RI Work Plan (SulTech 2006). Incorporation of these detection limits in the HHRA would have resulted in elevated risk estimates.

For several VOCs, semivolatile organic compounds (SVOC), and PAHs, analytical results were sometimes available for more than one analytical method for the same sample. For example, soil sample 105-S34-006 has naphthalene results using EPA analytical methods 8260B, 8270C, and 8270C-SIM. When more than one analytical method is available for a specific chemical for a specific sample, the Navy retained the result from the analytical method with the lowest detection limit. However, an exception was made for the naphthalene result for one sample (105-S34-047). The naphthalene concentration in this sample was 4.8 milligrams per kilogram (mg/kg) using EPA analytical method 8270C-SIM, 13 mg/kg using EPA analytical method 8270C, and it was not detected using EPA analytical method 8260 with a detection limit of 0.0047 mg/kg. The difference in concentrations is probably related to the heterogeneity of the soil sample. Thus, the maximum detected concentration of naphthalene (13 mg/kg) for sample 105-S34-047 was retained for this HHRA.

The HHRA applied the following rules whenever there were data from duplicate analyses.

- When both the original and duplicate measurement are either detected or censored (nondetect) and the results are in agreement (relative percent difference of concentrations is less than or equal to 50 percent), the original sample result will be retained and the duplicate result will be excluded.
- When one replicate measurement is detected and the other is a nondetect, the detected measurement will be retained and the nondetect result will be excluded.
- When both the original and duplicate measurements are detected or censored and the results are not in agreement, the maximum detected concentration will be used in the HHRA. The lower reporting limit will be used in the event of two censored measurements.

Validated soil analytical data were aggregated into the following subsets, corresponding to depth intervals deemed relevant for potential exposures:

- Surface soils, represented by soil samples collected from 0 to 2 feet below ground surface (bgs).
- Combined surface and subsurface soils, represented by all soil samples collected above 4 feet bgs (depth to groundwater).

### **H4.3 GROUNDWATER DATA**

This HHRA used groundwater data collected from sampling in 2006 during the RI from temporary probes DP1 through DP19 and from monitoring wells MW20 through MW24. The HHRA grouped all of the groundwater samples collected from these locations into a single data set. The HHRA excluded data collected before 2000 because it was considered too old to be representative of current site conditions. This includes the data from groundwater samples collected using a Hydropunch® in 1995 and a Geoprobe® in 1999. This HHRA applied the same rules used for soil data to address chemicals in groundwater analyzed by more than one analytical method and to address duplicate groundwater samples (see Section H4.2).

### **H4.4 SELECTION OF CHEMICALS OF POTENTIAL CONCERN**

COPCs are defined as the subset of chemicals at a site most likely to present a potential health risk. Tables H-2.1 and H-2.2 present the COPCs identified in soil, and Table H-2.3 presents the COPCs identified in groundwater. If a chemical was not detected in any of the data identified in Section H4.2 or H4.3, it was excluded as a COPC. The HHRA did not exclude any chemicals based on the frequency of detection or a comparison with screening criteria or background concentrations. Calcium, magnesium, potassium, and sodium, which are considered essential human nutrients, were excluded as COPCs. Based on the conceptual site model (CSM) for IR Site 34 and the potentially complete exposure pathways identified in Section H5.3, this HHRA only identified a chemical considered to be volatile as a COPC in groundwater.

Two-population statistical tests were used to compare metals concentrations in Site 34 soil samples with background concentrations determined for Alameda Point. The background comparison procedures are described in greater detail in Appendix G of the RI Report. The statistical tests determined that beryllium, mercury, and silver were below background concentrations and all other detected metals were above background concentrations. To evaluate the contribution of background risks to the total risk estimates, the HHRA estimated incremental risks by calculating the risks from background concentrations of metals in soil and subtracting the background risks from the total risk estimates. Section H8.4 discusses incremental risks.

## **H5.0 EXPOSURE ASSESSMENT**

The exposure assessment evaluates the nature and magnitude of potential exposures associated with IR Site 34. This assessment includes a description of the exposure setting and potential receptors, an identification of potential exposure pathways, and an estimation of EPCs and chemical intakes. The exposure assessment is based on the CSM. Figure H-1 presents the CSM for IR Site 34. The CSM summarizes information on sources of COPCs, affected environmental media, COPC release and transport mechanisms that may occur, potentially exposed receptors, and potential exposure pathways for each receptor. Sections H5.1, H5.2, and H5.3 further describe these components of the CSM.

### **H5.1 EXPOSURE SETTING AND POTENTIAL RECEPTORS**

IR Site 34 is a 4.18-acre area that is a partially paved, relatively flat open space. Except for the concrete pads, the Navy had all buildings, ASTs, GAPSs, transformers, and fuel lines removed from IR Site 34 between 1996 and 2000. IR Site 34 is currently unoccupied land. The planned reuse of this area is recreational and includes the development of a golf course. The CSM shown in Figure H-1 identifies the potential receptors evaluated in this HHRA. As described previously, recreational use is the planned reuse of the site and so future recreational users are potential receptors at IR Site 34. Although future development of the site for residential or industrial use may be unlikely, evaluation of these scenarios provides alternative risk estimates for unrestricted reuse of the site and supports risk management decisions for the site. As a conservative assumption, this HHRA also identified construction workers to be future receptors if the site is redeveloped.

Groundwater across Alameda Point is first encountered at depths between 3 to 8 feet bgs. Section 2.5 of the RI Report provides an evaluation of the groundwater use and the potential beneficial uses of groundwater beneath IR Site 34. Drinking water is currently supplied to Alameda Point by the East Bay Municipal Utilities District (Tetra Tech EM Inc. 2003). Groundwater beneath the central portions of Alameda Point (including IR Site 34) is not currently used for drinking water, irrigation, or industrial supply; and meets State Water Resources Control Board exemption criteria to de-designate the municipal supply beneficial use for portions of Alameda Point (Tetra Tech EM Inc. 2003). An evaluation of the potential beneficial uses of groundwater beneath IR Site 34 concluded groundwater beneath IR Site 34 is unlikely to be used as a potential drinking water source (see Section 2.5 of the RI Report). The EPA stated that based on (1) the shallow depth of the aquifer in this area, (2) the likelihood of

saltwater intrusion (based on directions of groundwater flow) if any significant pumping takes place, and (3) the fact that no wells currently exist within or close to this area, it seems unlikely that groundwater in this area will be a potential source of drinking water in the future (EPA 2000).

## **H5.2 POTENTIAL SOURCES OF SITE CHEMICALS**

Based on the results of previous investigations (Environmental Management Resources West, Inc. 1994; International Technology Corp. 2001; Bechtel Environmental, Inc. 2003), the most likely sources of chemicals detected at IR Site 34 are from the disposal of used sandblasting and paint grit; painting activities; chemical storage; sheet metal fabrication; spills near the GAP; leaks from ASTs; and the application of chemicals for weed control.

## **H5.3 IDENTIFICATION OF EXPOSURE PATHWAYS**

An exposure pathway is the means by which a chemical moves through the environment from the source to a receptor. Because the site is not currently used, no current receptors are present at the site. The following sections describe potentially complete exposure pathways associated with potential future receptors at IR Site 34. The CSM shown on Figure H-1 further illustrates the potentially complete exposure pathways identified for IR Site 34. Table H-1 also identifies the potentially complete exposure pathways.

### **H5.3.1 Future Commercial/Industrial Worker Exposure Pathways**

This HHRA conservatively assumed IR Site 34 may be redeveloped for commercial/industrial use in the future. This scenario assumes intrusive development of the existing site will occur and that excavation, construction, or regrading of the site may occur. Based on these conservative assumptions, the HHRA considered the following exposure pathways to be potentially complete:

- Soil ingestion
- Dermal contact with soil
- Inhalation of nonvolatile chemicals bound to airborne soil particulates
- Inhalation of volatile chemicals in indoor air that migrate from soil and/or groundwater in the vapor phase

### **H5.3.2 Future Construction Worker Exposure Pathways**

The HHRA considered the following exposure pathways to be potentially complete for future construction workers:

- Soil ingestion
- Dermal contact with soil
- Inhalation of nonvolatile chemicals bound to airborne soil particulates
- Inhalation of volatile chemicals in outdoor air from soil

Although it is acknowledged that construction workers also may have dermal contact with groundwater during excavation activities that intercept the shallow water table (located at about 3 to 8 feet bgs across the site), construction in saturated trench conditions is generally avoided and dewatering is quickly implemented for effective construction activities. Therefore, groundwater-related pathways of exposure for a construction worker are potentially complete, but are expected to be quantitatively negligible relative to all other pathways. Thus, the HHRA did not quantitatively evaluate these exposure pathways.

### **H5.3.3 Future Residential Exposure Pathways**

This HHRA conservatively assumed IR Site 34 may be redeveloped for residential use in the future. Although future development of the site for residential use may be unlikely, evaluation of this scenario will provide alternative risk estimates for unrestricted reuse of the site and will support risk management decisions for the site. This scenario assumes intrusive development of the site will occur and that excavation, construction, or regrading may occur. Based on these conservative assumptions, this HHRA considered the following exposure pathways to be potentially complete:

- Soil ingestion
- Dermal contact with soil
- Inhalation of nonvolatile chemicals bound to airborne soil particulates
- Inhalation of volatile chemicals in outdoor air
- Inhalation of volatile chemicals in indoor air that migrate from soil and/or groundwater in the vapor phase
- Ingestion of homegrown produce

Volatilization of chemicals in soil and groundwater, and the subsequent mass transport of these vapors into indoor spaces, may result in potential exposure via inhalation for residents in a future hypothetical residence. This HHRA identified volatile chemicals as those chemicals having a Henry's Law constant greater than  $10^{-5}$  (atmospheres-cubic meters per mole [atm·m<sup>3</sup>/mol]). In addition, Table 1 of DTSC guidance (2005a) lists chemicals that should be considered for the vapor intrusion pathway. As discussed in Section H5.1, groundwater at Site IR 34 is not

reasonably anticipated to serve as a public drinking water supply. Accordingly, this HHRA did not quantitatively evaluate domestic groundwater pathways because it considers groundwater ingestion and inhalation of volatiles during domestic use of groundwater to be incomplete exposure pathways.

### **H5.3.4 Future Recreational User Exposure Pathways**

Although IR Site 34 is currently vacant, the planned reuse of this area is recreational and includes the development of a golf course. The HHRA considered the following exposure pathways to be potentially complete for future recreational users:

- Soil ingestion
- Dermal contact with soil
- Inhalation of nonvolatile chemicals bound to airborne soil particulates
- Inhalation of volatile chemicals in outdoor air from soil

### **H5.4 EXPOSURE POINT CONCENTRATIONS**

Potential exposure points are identified on the basis of present and anticipated future population activity patterns and the relationship of the activities to the presence of contaminated media. A location is identified as an exposure point if a human might contact (for example, ingest) a contaminated medium (for example, soil) at that location. The chemical concentration in the medium (for example, subsurface soil) to which a receptor may be exposed is called the EPC. The HHRA calculated EPCs in soil based on data segregated into the following data sets:

- Surface Soil Data (0 to 2 feet bgs): Soil data from this depth interval were applied to commercial/industrial workers, construction workers, residents, and recreational users.
- Subsurface Soil Data (0 to 4 feet bgs): Because shallow groundwater is present at IR Site 34, soil data from the ground surface to the water table (located at approximately 4 feet bgs) were evaluated. Soil data from this depth interval were applied to commercial/industrial workers, construction workers, and residents.

EPCs were also calculated for COPCs in groundwater, outdoor air, and indoor air. The following sections describe the methods used to calculate EPCs in these media. Tables H-3.1 through H-3.6 also summarize the EPCs calculated for each medium and identify the specific methods used to calculate the EPC for each COPC.

## H5.4.1 Exposure Point Concentrations in Soil and Groundwater

This section describes the methods used to estimate EPCs in soil and groundwater. Tables H-3.1 and H-3.2 summarize the EPCs calculated for soil, and Table H-3.3 summarizes the EPCs calculated for groundwater. These tables also identify the specific methods used to calculate the EPC for each COPC. Calculations of EPCs in this HHRA followed methods recommended in EPA guidance (EPA 2004d, 2006a), as well as both standard texts on environmental statistics (Gilbert 1987) and more specialized sources dealing with the treatment of censored (nondetect) data (Helsel 2005). Appendix G provides additional detail on the equations and statistical tests used to estimate EPCs in soil and groundwater.

Initial selection of an approach for calculating descriptive statistics and EPCs was based on the relative sample size, detection frequency, and determination of the best-fit model for describing the underlying distribution of analytical results for each chemical. This HHRA used the following rules to estimate EPCs in soil and groundwater:

1. Detection frequencies were calculated for chemicals in individual data sets, and chemicals with no detected measurements were excluded from analysis. For chemicals with fewer than four detected measurements, the 95 percent upper confidence limit of the mean (95UCL) defaulted to the maximum detected concentration.
2. This HHRA did not use the laboratory detection limits to estimate EPCs if a detection limit exceeded the maximum detected concentration. Chapter 5 (Data Evaluation) in RAGS Volume I, Part A (EPA 1989), provides detailed guidelines for evaluating data usability for risk assessments, and recommends that unusually high quantification limits be removed in cases where they would cause the estimated EPCs to exceed the maximum detected datum in a sample. Helsel (2005) evaluates alternative methods for treating censored data in many routine calculations used in risk assessments, and states that these high censored measurements provide no useful information for estimating population parameters, and should always be eliminated. Tables H-2.1, H-2.2, and H-2.3 summarize the number of nondetected data that exceeded maximum detected concentrations.
3. Formal goodness-of-fit (GOF) tests were used to determine the underlying distribution for each chemical. The Shapiro-Wilk  $W$  test was used for normal and lognormal distributions, and the Cramer von Mises  $W^2$  test was used for gamma distributions. GOF tests were used only for chemicals with at least eight detected measurements. For chemicals with censored measurements, testing was conducted using detected data only. Distributions for chemicals not following a normal, lognormal, or gamma distribution, or having fewer than eight detected measurements, were treated as nonparametric. All GOF tests were evaluated at the 0.05 (5 percent) significance level.

4. For chemicals with detection frequencies of 100 percent, EPC methods were selected following recommendations in ProUCL 3.0 (EPA 2004c). In EPA (2004c), methods are selected based on the relative sample size and degree of skewness for each chemical distribution. The specific decision rules used to select the optimal method for calculating the 95UCL for normal, lognormal, gamma, and nonparametric distributions are provided in Section 5 of Appendix A (see Tables A1-A3) in EPA (2004c). Methods for calculating the 95UCL in accordance with EPA (2004c) include:

Parametric Methods

- Student's *t* UCL
- Approximate gamma UCL
- Adjusted gamma UCL
- Land's H-Statistic UCL
- Minimum variance unbiased estimate Chebyshev UCL

Nonparametric Methods

- Nonparametric Chebyshev UCL
- Bootstrap *t* UCL
- Hall's bootstrap UCL

5. For chemicals with one or more censored measurements, methods were selected following the recommendations in EPA (2006a). All methods following EPA (2006a) used the nonparametric Kaplan-Meier product limit estimator to calculate the mean. Confidence limits for the 95UCL were then estimated using one of the following methods:

- Student's *t* cutoff
- Chebyshev theorem
- Percentile bootstrap
- Bias-corrected accelerated bootstrap

6. The EPC was selected as the lesser of the 95UCL and the maximum detected concentration. It should be noted that following EPA (2004d, 2006a), the estimated 95UCL will not provide 95 percent coverage for the mean in all cases, especially for highly skewed distributions. For this reason, EPA (2004d, 2006a) suggests using estimates for the 97.5 percent upper confidence limit of the mean (97.5UCL) or 99 percent upper confidence limit of the mean (99UCL) in selected cases to ensure that the coverage is at least 95 percent. Cases where the 97.5UCL or 99UCL is more appropriate are discussed in EPA (2004d, 2006a).

#### **H5.4.2 Exposure Point Concentrations in Indoor Air**

This HHRA used EPA's vapor intrusion model for soil (EPA 2004a) and groundwater (EPA 2004b) to estimate indoor air concentrations in a future hypothetical commercial/industrial or residential building. EPA's vapor intrusion models are one-dimensional models based on the Johnson and Ettinger (1991) model that estimate convective and diffusive transport of chemical

vapors emanating from soil and groundwater into indoor spaces located directly above or near the source of contamination. The Johnson and Ettinger model assumes that all vapors from the underlying contaminated soil and groundwater have migrated vertically upward and are entering buildings through gaps and openings at seams between the subgrade walls and concrete slabs (or foundations). The model refers to these gaps as “floor-wall seam crack” (EPA 2004a, 2004b). The model ignores attenuating factors, such as biological degradation. Many of the exposure assumptions used to estimate risks from the indoor air pathway are highly conservative and may have overestimated risks. For these reasons, it is a conservative screening tool to estimate maximum indoor air concentrations and risks. Guidance by EPA (2002c, 2004d) and DTSC (2005a) provide additional details on the modeling equations and input parameters used in the vapor intrusion model. Section H9.2.5 discusses uncertainties associated with the vapor intrusion model.

Input parameters applied to the vapor intrusion models include chemical properties of the contaminant, soil and groundwater properties, and structural/dimensional properties of the buildings evaluated (EPA 2002c). The HHRA modified EPA vapor intrusion models (EPA 2004a, 2004b) by replacing the default input parameters in EPA’s vapor intrusion models with California-specific input parameters listed in DTSC’s vapor intrusion model (DTSC 2005a). Attachment H1 provides the spreadsheets of the vapor intrusion models used to calculate indoor air concentrations. Table H1-1 in Attachment H1 summarizes the input parameters used in the vapor intrusion models. Table H1-2 of Attachment H1 presents the indoor air concentrations estimated for volatile COPCs in soil, and Table H1-3 of Attachment H1 presents the indoor air concentrations estimated for volatile COPCs in groundwater. The following sections discuss the input parameters used in the vapor intrusion models.

#### **H5.4.2.1      *Chemical Properties***

This HHRA identified volatile chemicals as those chemicals having a Henry’s Law constant greater than  $10^{-5}$  atm·m<sup>3</sup>/mol. In addition, Table 1 of DTSC guidance (2005a) lists chemicals that should be considered for the vapor intrusion pathway. The EPCs estimated for volatile COPCs in subsurface soil (0 to 4 feet bgs) and groundwater were applied to the vapor intrusion models to estimate indoor air concentrations. Table H1-2 of Attachment H1 includes the EPCs for volatile COPCs in subsurface soil (0 to 4 feet bgs), and Table H1-3 of Attachment H1 includes the EPCs for volatile COPCs in groundwater.

#### **H5.4.2.2      *Soil and Groundwater Properties***

Soil and groundwater properties used in the vapor intrusion models include average soil and groundwater temperature, thickness of soil stratum evaluated, depth to groundwater, soil type, organic carbon content in soil, soil density, and total porosity. Table H1-1 of Attachment H1 presents the source and the basis for selecting the input parameters used to evaluate the vapor intrusion pathway. Soil at IR Site 34 primarily consists of poorly sorted sand. The selection of the soil type at IR Site 34 for use in the vapor modeling was based on a comparison of lithologic data, including boring logs, for IR Site 34. This HHRA used default parameters for dry bulk density, total porosity, and vadose zone soil-water filled porosity based on the soil type (sand).

For the evaluation of vapors from bulk soil sources, the soil depth below grade to the top of soil contamination for IR Site 34 was assumed to be directly under the slab, since the shallowest detected chemical is near ground surface (15 centimeters bgs). Additionally, the soil depth below grade to the bottom of contamination was assumed to be the average depth to groundwater at IR Site 34. The vapor intrusion model for soil is based on a finite source. The model is constructed in a manner that evaluates a finite source since soil contamination was assumed to extend from the surface to the soil-groundwater interface. The vapor intrusion model for groundwater is based on an infinite chemical source.

#### **H5.4.2.3 Building Properties**

For the evaluation of the future commercial/industrial worker the building dimensions of a hypothetical future building were used. The building size for the hypothetical future commercial/industrial building was based on the upper end of the range for residential structures because no default commercial/industrial values were available (EPA 2002c). Use of this building size will present a conservative exposure scenario for the future commercial/industrial worker because residences are typically smaller than most commercial/industrial buildings.

For the evaluation of the future resident the building size of a hypothetical future residence was used. The building size for the hypothetical future residence is conservative; it is based on the lower end of the range (most protective default) for residential structures (EPA 2002c). Table H1-1 in Attachment H1 presents the dimensions of the future hypothetical buildings used to evaluate the vapor intrusion pathway.

The evaluation was based on buildings with slab-on-grade construction (no basements or crawlspaces) because of the shallow depth to groundwater. The foundation was assumed to be 15 centimeters thick for the hypothetical future commercial/industrial building and 10 centimeters thick for the hypothetical future residence. The vapor intrusion model assumes that vapor infiltration is through cracks in the foundation and below-grade walls, if any exist (EPA 2002c). The area of cracks through which vapors can pass was assumed to be equal to a 0.1-centimeter-wide crack for both the hypothetical future commercial/industrial building and residence.

The building ventilation rate is another characteristic used in the vapor intrusion model. The building ventilation rates for a hypothetical future commercial/industrial building (1.0 air changes per hour) and for the hypothetical future residence (0.5 air changes per hour) were adapted from "Guidance for the Evaluation and Migration of Subsurface Vapor Intrusion to Indoor Air" (DTSC 2005a).

Buildings can develop negative pressures relative to ambient pressure as a result of temperature gradients and wind effects. These pressure differences (dP) affect contaminant flux into buildings and are considered in the vapor intrusion model. Typical dP values are 10 to 100 grams per centimeter per second squared ( $\text{g}/\text{cm}\cdot\text{s}^2$ ). The soil-building pressure differential used in this evaluation ( $40 \text{ g}/\text{cm}\cdot\text{s}^2$ ) is the recommended value from DTSC's guidance (2005a) and EPA's guidance (2002c).

The average vapor flow rate into the building (referred to as  $Q_{\text{soil}}$  in the model) is set to the model default of 10 liters per meter (L/m) for hypothetical future commercial/industrial buildings and 5 L/m for hypothetical future residences. The residential rate is recommended by EPA guidance (2002c) and DTSC guidance (2005a) for small buildings, which was proportionally increased based on building dimensions for the hypothetical future commercial/industrial buildings.

#### **H5.4.3 Outdoor Air – Chemicals in Particulates Released from Soil**

EPCs of particulates released from soil to outdoor air were estimated using soil EPCs as the source term and the methodology provided by EPA Region 9 describing the derivation of preliminary remediation goals (PRG) (EPA 2004e). To derive the EPCs in outdoor air, the soil EPC was multiplied by the reciprocal of the derived particulate emission factor (PEF). The PEF is a nonchemical-specific value that relates chemical concentrations in soil to airborne concentrations that may be inhaled. The PEF value used for commercial/industrial workers and residents was  $1.32 \times 10^9$  cubic meters per kilogram and the construction worker PEF value was  $1.00 \times 10^6$  cubic meters per kilogram. These values were based on the default value recommended by DTSC for use in risk assessments at California military facilities (DTSC 2005c). EPCs for particulate chemicals released from surface soil and subsurface to outdoor air are calculated within the intake equation shown in Table H-4.1. Therefore, a separate set of RAGS Part D standard Table 3s is not presented for outdoor air for chemicals in particulates released from soil.

#### **H5.4.4 Outdoor Air – Volatile Chemicals Released from Soil**

Chemical-specific volatilization factors (VF), which relate concentrations of volatile chemicals in soil or groundwater to airborne concentrations, were used to estimate concentrations in outdoor air from volatile COPCs released from soil. The HHRA calculated site-specific VFs using the equation provided in the EPA Region 9 PRGs (EPA 2004e). Tables H-3.4 and H-3.5 present the EPCs for ambient air for volatile chemicals released from surface soil (0 to 2 feet bgs) and subsurface soil (0 to 4 feet bgs), respectively. These tables also provide the input parameters used to estimate these EPCs. To estimate EPCs in outdoor air, the soil EPC was multiplied by the reciprocal of the VF.

#### **H5.4.5 Outdoor Air – Volatile Chemicals Released from Groundwater**

Chemical-specific VFs also were used to estimate concentrations in outdoor air from volatile COPCs released from groundwater. The HHRA calculated site-specific VFs using the equation provided in an ASTM International (1995) emission model. Table H-3.6 presents the EPCs for ambient air for volatile chemicals released from groundwater. This table also provides the equations and the input parameters used to estimate these EPCs.

## H5.5

### CHEMICAL INTAKES AND EXPOSURE PARAMETERS

Consistent with EPA guidance (1995), the HHRA calculated exposure intake estimates for central tendency exposure (CTE) and reasonable maximum exposure (RME) for commercial/industrial workers, construction workers, residents, and recreational users at IR Site 34. As indicated by EPA (1989), "actions at Superfund sites should be based on an estimate of the reasonable maximum exposure expected to occur under both current and future land-use conditions." The average exposure is the most likely exposure expected to occur at the site and is calculated using the EPC and CTE exposure parameters. This HHRA calculated chemical intakes using the EPCs described in Section H5.4 and scenario-specific assumptions and intake parameters.

EPA-derived exposure algorithms were used to estimate the chemical intakes for each route of exposure. Equation H-1 is a generic equation for calculating chemical intake (EPA 1989):

$$I = \frac{C \times CR \times EF \times ED}{BW \times AT} \quad (H-1)$$

where

- I = Intake (the amount of chemical at the exchange boundary in milligrams per kilogram per day [mg/kg-day])
- C = Chemical concentration (such as the EPC in mg/kg for soil, micrograms per liter [ $\mu\text{g/L}$ ] for groundwater, and milligrams per cubic meter [ $\text{mg/m}^3$ ] for air)
- CR = Contact rate (the amount of contaminated medium contacted per unit of time or event; may be the ingestion rate, inhalation rate, or dermal contact rate; for example, milligrams per day [mg/day] for the ingestion rate of soil)
- EF = Exposure frequency (how often the exposure occurs in days per year)
- ED = Exposure duration (the number of years in which a receptor comes in contact with the contaminated medium)
- BW = Body weight (the average body weight of the receptor over the exposure period in kilograms)
- AT = Averaging time (the period in days over which exposure is averaged; for carcinogens, the averaging time is 25,550 days on the basis of a lifetime exposure of 70 years [average life expectancy], and for noncarcinogens, the averaging time is equal to the exposure duration multiplied by the number of days in a year [365 days])

Pathway-specific variations of Equation H-1 were used to calculate intakes of COPCs. Section H5.5.1 discusses the exposure parameters common to all equations, and Section H5.5.2 discusses pathway-specific equations and exposure parameters.

### **H5.5.1 General Exposure Assumptions**

The equations and values used to calculate daily intake are summarized in RAGS Part D Standard Tables (see Tables H-4.1 through H-4.4). Exposure parameters common to all intake equations include exposure time, exposure frequency, exposure duration, body weight, and averaging time. As shown in Tables H-4.1 through H-4.4, standard EPA and Cal/EPA default exposure factors were used for exposure time, exposure frequency, exposure duration, averaging time, and body weight for future commercial/industrial workers, construction workers, and residents at Site 34 (EPA 1991; DTSC 1992, 2005c).

Currently, a golf course is the planned reuse of the IR Site 34 area. Recreational RME scenario assumptions included use of the golf course for 4.1 hours per day, 75 days a year and CTE assumptions of 3.85 hour per day, 75 days per year. RME exposure durations were based on the 95UCL time spent in active leisure (5.9 hours per week) in the Western region as cited in Table 15-153 in EPA's Exposure Factors Handbook (EPA 1997a). The RME exposure assumption for an adult would equate to a little more than 1 round of golf every week. The HHRA conservatively assumed IR Site 34 also could be developed as a park and a recreational child could spend 1 hour per day, 75 days per year at a park at IR Site 34.

### **H5.5.2 Pathway-Specific Exposure Factors**

This section summarizes the exposure factors unique to each of the exposure pathways quantified in this HHRA. Tables H-4.1 through H-4.4 also present the pathway-specific exposure factors used to quantify exposure for each receptor.

#### ***H5.5.2.1 Exposure Parameters for Inhalation of Volatile and Particulate Chemicals***

The exposure parameter specific to the assessment of the inhalation pathway is the inhalation rate. A residential inhalation rate of 0.42 cubic meters per hour ( $\text{m}^3/\text{hr}$ ) was used for the child resident and 0.83  $\text{m}^3/\text{hr}$  was used to evaluate the adult resident (EPA 1991). To estimate chemical intake from inhalation of volatile and particulate chemicals, a default value of 1.75 cubic meters per hour ( $\text{m}^3/\text{hr}$ ) (corresponding to 14 cubic meters per day [ $\text{m}^3/\text{day}$ ] for an 8-hour workday) was used for the inhalation rate for a commercial/industrial worker and a default value of 2.5  $\text{m}^3/\text{hr}$  (corresponding to 20  $\text{m}^3/\text{day}$  for an 8-hour workday) was used for the inhalation rate for a construction worker (EPA 1991; DTSC 2005c). The residential inhalation rates were used for recreational users.

#### **H5.5.2.2 Exposure Parameters for Incidental Ingestion of Soil**

Exposure parameters specific to the ingestion of soil pathway are the soil ingestion rate and the fraction of the ingested soil assumed to be contaminated. This HHRA conservatively assumed all soil contacted is contaminated (that is, the fraction ingested was set equal to 1). Estimated soil ingestion rates were 200 mg/day for the child and 100 mg/day for the adult resident. Different ingestion rates were necessitated, given children's mouthing habits, which are assumed to result in greater incidental soil intakes during the preschool years (EPA 1991, 2001c). Default soil ingestion rates were used for the workers: 100 mg/day for the commercial/industrial worker and 330 mg/day for the construction worker (EPA 1991, 2002d). The residential ingestion rates were assumed for recreational users.

#### **H5.5.2.3 Exposure Parameters for Dermal Contact with Soil**

Exposure parameters specific to the assessment of the dermal pathway are the skin surface area (the amount of skin in contact with soil), the amount of soil adhering to the skin (adherence factor), and the chemical-specific dermal absorption fraction (ABS) (that is, the fraction of chemical in contact with the skin that actually crosses the skin barrier). ABS factors are taken from DTSC (1994). In the absence of a chemical-specific ABS, a default ABS of 0.1 is assumed for SVOCs, and a default ABS of 0.01 is assumed for inorganic chemicals (DTSC 1994). Table H-5.1 presents the ABS values.

Receptor-specific values for the dermal adherence factor were provided by DTSC (2000): 0.2 milligrams per square centimeter ( $\text{mg}/\text{cm}^2$ ) for the commercial/industrial worker; 0.8  $\text{mg}/\text{cm}^2$  for the construction worker, 0.2  $\text{mg}/\text{cm}^2$  for the resident child, and 0.07  $\text{mg}/\text{cm}^2$  for resident adult.

Values for body surface area were taken from DTSC (2000): 5,700 square centimeters ( $\text{cm}^2$ ) for commercial/industrial and construction workers, 2,900  $\text{cm}^2$  for child residents, 5,700  $\text{cm}^2$  for adult residents.

In accordance with EPA guidance, the daily dermal absorption factor was not adjusted for the length of time because of a lack of scientific information on the absorption of chemicals over shorter periods than a day (EPA 2001b). Therefore, the same amount of dermal absorption is assumed for the residential and recreational scenarios.

#### **H5.5.2.4 Ingestion of Homegrown Produce**

Ingestion of COPCs that are transferred from soil to homegrown produce via uptake through plant roots was evaluated for the residential exposure scenario. Direct measurements of chemical concentrations in homegrown produce are not available for IR Site 34 because homegrown produce is not currently grown at Alameda Point. EPCs for homegrown produce were calculated based on EPCs for COPCs in soil and soil-to-plant uptake factors that estimate the root uptake of inorganic and organic chemicals in soil and translocation of chemicals to

edible plant parts (U.S. Department of Energy 1984). Table H-5.2 lists the uptake factors for each COPC in soil.

Uptake factors for inorganic COPCs were obtained from (U.S. Department of Energy 1984). The EPC for soil was multiplied by the uptake factor to estimate EPCs in homegrown produce from inorganic COPCs.

Equations from Cal/EPA were used to derive the uptake factors for nonvolatile organic COPCs (Cal/EPA 2003). These equations relate the octanol-water partition coefficient ( $K_{ow}$ ) and the organic carbon-water partition coefficient ( $K_{oc}$ ) of the contaminant and the fraction of organic carbon ( $F_{oc}$ ) in the soil to calculate the uptake factor. The equation used to calculate the uptake factor is as follows:

$$UF = \frac{(0.03 \times K_{ow}^{0.77}) + 0.82}{(K_{oc})(F_{oc})} \quad (H-2)$$

where

- $UF$  = Soil-to-plant uptake factor
- $K_{ow}$  = Octanol-water partition coefficient (cubic centimeters per gram)
- $K_{oc}$  = Organic carbon-water partition coefficient (cubic centimeters per gram)
- $F_{oc}$  = Fraction organic carbon in soil (unitless)

$F_{oc}$  was assumed to be 0.1, a value appropriate to soil used for the production of food crops (Cal/EPA 2003). If  $K_{oc}$  values are unavailable, they were estimated based on chemical-specific  $K_{ow}$  values using the following equation (Lyman and others 1990):

$$\log K_{oc} = \log K_{ow} - 0.21 \quad (H-3)$$

Consistent with EPA guidance, a correction factor was applied to lipophilic COPCs (EPA 1998). Lipophilic chemicals were defined for this HHRA as polychlorinated biphenyls (PCB), PAHs, pesticides, and SVOCs. EPA (1998) recommends a correction factor of 0.01 for lipophilic COPCs ( $\log K_{ow}$  greater than 4); that is, the uptake factor calculated for lipophilic COPCs using Equation H-2 should be multiplied by the correction factor of 0.01 to calculate a corrected uptake factor. EPA does not recommend use of a correction factor for COPCs with a  $\log K_{ow}$  less than 4. Table H-5.2 lists the uptake factors for nonvolatile organic COPCs derived using the above equations and the values and sources of the chemical data used to derive the uptake factors.

Risks associated with VOCs were not evaluated in the homegrown produce pathway. VOCs are typically low-molecular-weight chemicals that do not persist or bioaccumulate in the

environment (EPA 1994a). In addition, VOCs are expected to be lost during soil tilling, planting, and food preparation, such as peeling, cleaning, and cooking.

EPA estimates that homegrown fruits and vegetables account for 4 percent and 6.8 percent, respectively, of receptor diets (EPA 1997a). Using the 95th percentile of fruit and vegetable intakes (12 grams per kilogram per day [g/kg-day] and 10 g/kg-day, respectively) to estimate the RME homegrown produce consumption rates, a 70 kilogram adult would ingest 33.6 grams per day (g/day) of homegrown fruits and 47.6 g/day of homegrown vegetables. A child weighing 15 kilograms would ingest 7.2 and 10.2 grams per day of homegrown fruits and vegetables, respectively. Accordingly, the corresponding RME homegrown produce consumption rates (the total of fruit and vegetable consumption rates) are 81.2 g/day for the adult resident and 17.4 g/day for the child resident. To evaluate the CTE scenario, EPA recommends intake rates of 3.4 g/kg-day for fruits and 4.3 g/kg-day for vegetables. Applying the same fraction of 4 percent and 6.8 percent of homegrown fruits and vegetables, respectively, in a typical receptor diet as assumed in the RME scenario, an adult resident in a CTE scenario would ingest 9.5 g/day of fruits and 20.5 g/day of vegetables, for a total of 30 g/day. A child resident in a CTE scenario would ingest 2 g/day of fruits and 4.4 g/day of vegetables, for a total of 6.4 g/day.

## H6.0 TOXICITY ASSESSMENT

The objective of the toxicity assessment for IR Site 34 is to evaluate the relationship between dose and toxic response for each COPC identified in the COPC selection process. The toxicity assessment identifies toxicity criteria (values) for each chemical chosen for inclusion in the risk assessment and the kind of effect each chemical could produce. The toxicity values used in the HHRA are cancer slope factors (SF) (in units of [mg/kg-day]<sup>-1</sup>) for cancer effects and reference doses (RfD) (in units of mg/kg-day) for chronic exposures associated with noncancer effects.

The HHRA used a dual-tracking approach to take into consideration both EPA and DTSC toxicity values. To satisfy federal (Navy and EPA) and state (DTSC) requirements, this HHRA prepared a set of risk assessment results using EPA toxicity values, referred to as Method 1, and a separate set of risk assessment results using DTSC toxicity values, referred to as Method 2.

Toxicity factors for Method 1 were compiled from EPA-approved sources using the following hierarchy:

- EPA's Integrated Risk Information System (IRIS) Values: IRIS is an on-line database that contains EPA-approved RfDs and SFs (or reference concentrations [RfC] and unit risk factors converted to RfDs and SFs) (EPA 2007). The RfDs and SFs have undergone extensive review and have agency-wide consensus.
- EPA's Provisional Peer-Reviewed Toxicity Values (PPRTV): PPRTVs are presented in the EPA Region 9 PRG table (EPA 2004e). PPRTVs were developed by the Office of Research and Development/National Center for Environmental Assessment, and Superfund Health Risk Technical Support Center when requested by EPA's Superfund program (EPA 2004f).

- Other EPA Sources: These sources include provisional values from the National Center for Environmental Assessment as presented in the EPA Region 9 PRG table (EPA 2004e), and EPA's Health Effects Assessment Summary Tables (EPA 1997b).

Toxicity factors for Method 2 used State of California SFs developed by the Office of Environmental Health Hazard Assessment (OEHHA). These SFs are available from the "Toxicity Criteria Database" (OEHHA 2007). If an OEHHA SF was not available, the EPA hierarchy was followed to select SFs. In addition to SFs, OEHHA has developed reference exposure levels (REL) to assess noncancer endpoints of inhalation exposures (OEHHA 2005); however, RELs have not been subject to as stringent a peer review as federal RfCs available from IRIS. As a result, the HHRA used the prioritization summarized below for inhalation noncancer toxicity values in the risk characterization of COPCs selected under Method 2:

- The EPA IRIS RfC or inhalation RfD will be used if the value is based on an inhalation study.
- The OEHHA REL will be used if the EPA IRIS inhalation RfD has been extrapolated from an oral study.
- The OEHHA REL will be used if no EPA IRIS RfC or inhalation RfD value is available.
- An alternative source (such as PPRTVs, HEAST, route-extrapolated values) will be used if no EPA IRIS RfC or inhalation RfD value is available and no OEHHA REL is available.

Finally, because OEHHA has not developed its own set of toxicity values for assessing noncancer endpoints for oral or dermal exposures, the EPA hierarchy was followed to select noncancer oral and dermal toxicity values for risk characterization of the COPCs identified under Method 2.

## **H6.1 REFERENCE DOSES**

The potential for adverse noncancer health effects to result from exposure to chemicals was characterized by comparing an exposure estimate (intake) with an RfD. EPA (1989, 2006a) defines an RfD as an estimate (with uncertainty that spans perhaps an order of magnitude or more) of a daily exposure level for the human population, including sensitive subpopulations, who are likely to be without an appreciable risk of harmful effects. The RfDs are expressed as mg/kg-day and are specific to the chemical, exposure route (for example, ingestion or inhalation), and exposure duration (chronic or subchronic).

RfDs to assess oral exposures and RfCs to assess inhalation exposure are provided in the various sources for toxicity values identified in Section H6.0. The RfCs are concentrations in air expressed as mg/m<sup>3</sup> and were converted to RfDs using the following equation:

$$RfD = \frac{RfC \times IR}{BW} \quad (H-4)$$

where

RfD	=	Reference dose (mg/kg)
RfC	=	Reference concentration (mg/m <sup>3</sup> )
IR	=	Inhalation rate assumption (20 m <sup>3</sup> /day)
BW	=	Body weight assumption (70 kilograms)

Consistent with guidance from DTSC (1992), oral RfDs were used to assess dermal exposure in the absence of route-specific dermal RfDs, as detailed in Section H6.3. Chronic RfDs are developed for evaluating exposures that occur over periods of more than 7 years, and subchronic RfDs are for exposures of less than 7 years. Although the potential exposures considered in this HHRA are for periods of from 1 to 30 years, chronic RfDs were used to evaluate both chronic and subchronic exposures.

RfDs and RfCs are derived by EPA work groups. The EPA work groups review all relevant human and animal studies for each chemical and select the study (or studies) pertinent to deriving the specific RfD. RfDs are often derived from a measured or estimated no observed adverse effect level (NOAEL). The NOAEL corresponds to the dose, in mg/kg-day, that can be administered without inducing observable adverse effects. If a NOAEL cannot be established, the lowest observed adverse effect level (LOAEL) is used. The LOAEL corresponds to the lowest daily dose administered that induces an observable adverse effect. The toxic effect characterized by the LOAEL is referred to as the “critical effect.”

NOAELs are most often based on data from experimental studies in animals. Both the experimental parameters and the extrapolation of animal data to humans are potential sources of uncertainty; therefore, the NOAEL or LOAEL is divided by uncertainty factors in deriving an RfD to ensure that the RfD will be protective of human health. The uncertainty factors usually occur in multiples of 10, and each factor represents a specific area of uncertainty inherent in the extrapolation from available data. Uncertainty factors account for the following:

- Extrapolation of data from animals to humans (interspecies extrapolation)
- Variation in human sensitivity to the toxic effects of a chemical (intraspecies differences)
- Derivation of a chronic RfD based on a subchronic rather than a chronic study
- Derivation of a RfD based on a LOAEL rather than a NOAEL

Modifying factors between 0 and 10 also may be applied to accommodate other factors or additional uncertainty associated with the data. The modifying factor is 1 for most chemicals. Tables H-6.1 and H-6.2 present the Method 1 RfDs used in this HHRA, and Tables H-6.5 and H-6.6 present the Method 2 RfDs used in this HHRA.

## H6.2 SLOPE FACTORS

The toxicity information considered in the assessment of potential cancer risks includes a weight-of-evidence classification and a SF. The weight-of-evidence classification qualitatively describes the likelihood that a chemical is a human carcinogen and is based on an evaluation of the available data from human and animal studies. The EPA guidelines in "Proposed Guidelines for Carcinogen Risk Assessment" (EPA 1996b) were used to evaluate the chemicals. These chemicals were classified using an alphanumeric system in which the chemical was assigned to one of the following groups: Group A, a known human carcinogen; Groups B1 and B2, a probable human carcinogen; and Group C, a possible human carcinogen. Chemicals that could not be classified as human carcinogens because of lack of data were categorized in Group D, and chemicals for which there was evidence of noncarcinogenicity in humans were categorized in Group E. After the publication of the 1996 EPA guidelines, the chemicals evaluated by EPA were addressed using a weight-of-evidence narrative and one of the following descriptors for classifying potential carcinogenicity to humans: "known/likely," "cannot be determined," and "not likely."

A SF is an upper-bound estimate, approximating a 95UCL on the increased cancer risk from lifetime exposure to a chemical (EPA 1989). The SFs used to assess cancer risk were obtained from the sources identified in Section H6.0.

Similar to RfDs, SFs are specific to the chemical and route of exposure and are available for oral and inhalation exposures. EPA typically publishes inhalation unit risks instead of inhalation SFs. The unit risks were converted to inhalation SFs using the following equation:

$$SF = \frac{UR \times BW \times UCF}{IR} \quad (H-5)$$

where

SF	=	Slope factor (mg/kg-day) <sup>-1</sup>
UR	=	Unit risk (mg/m <sup>3</sup> )
BW	=	Body weight assumption (70 kilograms)
UCF	=	Unit conversion factor (1,000 micrograms per milligram)
IR	=	Inhalation rate assumption (20 m <sup>3</sup> /day)

As with RfDs, oral SFs were used to estimate cancer risks for exposures via the dermal route because no dermal SFs were available, as detailed in Section H6.3. Tables H-6.3 and H-6.4 present the Method 1 SFs used in this HHRA, and Tables H-6.7 and H-6.8 present the Method 2 SFs used in this HHRA.

### **H6.3 ROUTE-TO-ROUTE EXTRAPOLATION**

Toxicity values are available for only one route of exposure (that is, for only the inhalation or the oral exposure routes) for some chemicals. In some of these cases, route-to-route extrapolations were conducted so that toxicity values developed for one route of exposure (for example, the oral route) were applied to another (for example, the inhalation route). This approach assumes that toxicity is identical regardless of the route of exposure. Route-to-route extrapolations are recommended for organic chemicals by the State of California (DTSC 1992) and are used by EPA Region 9 to develop PRGs (EPA 2002b).

In this HHRA, route-to-route extrapolations were used for organic COPCs in the following cases:

- If an oral toxicity value (RfD or SF) had been assigned for an organic chemical but no inhalation toxicity value was available, the oral toxicity value also was used as the inhalation toxicity value.
- If an inhalation toxicity value had been assigned for an organic chemical but no oral toxicity value was available, the inhalation toxicity value also was used as the oral toxicity value.

These route-to-route extrapolations were not used for metals because their toxicological endpoints depend heavily on the exposure route (EPA 2004f). Route-to-route extrapolations for the RfDs and SFs used in the HHRA are denoted with an "R" (for route extrapolated) in Tables H-6.1 through H-6.8.

Oral absorption efficiency was assumed to be 100 percent for all COPCs; that is, oral toxicity values were not adjusted for absorption efficiency to evaluate the dermal pathway.

### **H6.4 SURROGATES**

Because of a lack of toxicity values for some COPCs, chemical surrogates were used to avoid data gaps in the HHRA. Chemical surrogates were selected based on similar chemical structure and are identified in Tables H-6.1 through H-6.8.

### **H6.5 LEAD**

Lead is a chemical of particular toxicological concern wherever child receptors and other sensitive subpopulations may be exposed to lead-contaminated media. However, no accepted

toxicity values are available for lead. Evaluation of lead in the HHRA is based on cancer effects. The potential for human health effects caused by lead was estimated through blood-lead concentration modeling. DTSC's LeadSpread Version 7 model (DTSC 1999) was used to estimate blood-lead concentrations in residential adults and children, and the resulting blood-lead concentrations were compared with target blood-lead levels established by DTSC.

## H7.0 RISK CHARACTERIZATION METHODS

The final step in the HHRA is the characterization of the potential risks associated with exposure to detected chemicals. Cancer risks and noncancer health hazards are characterized separately. Sections H7.1 and H7.2 present the general methodology for characterizing cancer risks and noncancer hazards. Section H7.3 presents the methodology for evaluating lead.

### H7.1 CHARACTERIZATION OF CANCER RISKS

Risks associated with exposure to chemicals classified as carcinogens are estimated as the incremental probability that an individual will develop cancer over a lifetime as a direct result of an exposure (EPA 1989). The estimated risk is expressed as a unitless probability.

In the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), EPA defined general remedial action goals for sites in the National Priorities List (Title 40 of the *Code of Federal Regulations* Part 300.430). The goals included a range for residual cancer risk, which is "an excess upper bound life-time cancer risk to an individual of between  $10^{-4}$  and  $10^{-6}$ ," or 1 in 10,000 to 1 in 1,000,000. The NCP states "the  $10^{-6}$  risk level shall be used as the point of departure for determining remediation goals." Using this criteria as a general guide, the HHRA called a COPC a "risk driver" when the COPC-specific cancer risk exceeds  $1 \times 10^{-6}$  or the COPC-specific hazard quotient (HQ) exceeds 1.

For chemicals classified as carcinogens, three steps are used in estimating cancer risks. First, to derive a cancer risk estimate for a single chemical and pathway, the chemical intake is multiplied by the chemical-specific SF. The calculation is based on the following relationship:

$$\text{Chemical-Specific Cancer Risk} = \text{Intake (mg/kg-day)} \times \text{SF (mg/kg-day)}^{-1} \quad (\text{H-7})$$

Second, to estimate the cancer risk associated with exposure to multiple carcinogens for a single exposure pathway, the individual chemical cancer risks are assumed to be additive, as follows:

$$\text{Pathway-Specific Cancer Risk} = \sum \text{Chemical-Specific Cancer Risk} \quad (\text{H-8})$$

Third, pathway-specific risks are summed to estimate the total cancer risk.

## H7.2 CHARACTERIZATION OF NONCANCER HAZARDS

For chemicals that are not classified as carcinogens and for those carcinogens known to cause adverse health effects other than cancer, the potential for exposure to result in adverse health effects other than cancer is evaluated by comparing the intake with an RfD. When calculated for a single chemical, the comparison yields a ratio termed the HQ:

$$HQ = \frac{\text{Intake (mg/kg-day)}}{\text{RfD (mg/kg-day)}} \quad (\text{H-9})$$

To evaluate the potential for adverse health effects other than cancer from simultaneous exposure to multiple chemicals, the HQs for all chemicals are summed, yielding a hazard index (HI) as follows:

$$HI = \sum HQ \quad (\text{H-10})$$

Pathway-specific HIs are then summed to estimate a total HI for each receptor. An HI of less than 1 indicates that adverse noncancer health effects are not expected. If the total HI exceeds 1, further evaluation in the form of a segregation of the HI via a target organ analysis may be performed to assess whether the noncancer HIs are a concern (EPA 1989). Target organ HIs greater than 1 may indicate a potential adverse effect. In cases where the total HI exceeded 1 and the HQ for an individual COPC also exceeded 1, a target organ analysis was not conducted because the HQ results for the individual COPC already indicate concern may be warranted.

## H7.3 HEALTH EFFECTS ASSOCIATED WITH EXPOSURE TO LEAD

No consensus-based toxicity values are available for lead, which is a chemical of particular toxicological concern wherever child receptors and other sensitive subpopulations may come into contact with lead-contaminated media. The potential for human health effects caused by lead is typically estimated on the basis of blood-lead concentrations. Mathematical models have been developed to estimate blood-lead levels on the basis of total lead uptake from exposures by diet, drinking water, air, and soil. In this case, DTSC's LeadSpread model (Version 7.0) was used to calculate blood-lead levels for a future adult and child resident at IR Site 34 (DTSC 1999). In addition to the soil EPCs for lead in soil, this HHRA used default values recommended in the DTSC Leadsread model to estimate blood lead concentrations for a resident child and adult. Default values used included the DTSC MCL of 15 µg/L in drinking water; the highest monthly average value from a California monitoring station of 0.028 micrograms per cubic meter (µg/m<sup>3</sup>) for ambient air; and a respirable dust concentration of 1.5 µg/m<sup>3</sup>, based on soil screening guidance (EPA 1996a). The homegrown produce contribution was set to the default value for residential scenarios (7 percent). It is assumed that 7 percent of the diet consists of homegrown produce, based on the Exposure Factors Handbook (EPA 1997a).

Section H8.3 presents the results of the blood lead modeling. The estimated blood-lead levels were compared with benchmark blood-lead levels established by the DTSC. DTSC recommends

using a blood-lead level of 10 micrograms per deciliter ( $\mu\text{g}/\text{dL}$ ) as a benchmark to be protective of the general population (DTSC 1999). This HHRA used the current EPA Region 9 PRG for lead of 800 mg/kg for industrial soil as a benchmark for evaluating commercial/industrial workers. Although LeadSpread was also designed to estimate blood-lead levels for occupational exposures, DTSC is not currently recommending the use of this model for assessment of exposure to lead under an occupational setting (DTSC 2005b). The lead EPCs for surface soil (0 to 2 feet bgs) and subsurface soil (0 to 4 feet bgs) were compared with the PRG of 800 mg/kg for industrial soil.

## **H8.0 RESULTS OF THE HUMAN HEALTH RISK ASSESSMENT**

This section summarizes the potential risks estimated for future commercial/industrial workers, construction workers, residents, and recreational users at IR Site 34. This HHRA used a dual-tracking approach to consider both EPA and DTSC toxicity values. To satisfy federal (Navy and EPA) and state (DTSC) requirements, the HHRA prepared a set of risk assessment results using EPA toxicity values, referred to as Method 1, and a separate set of risk assessment results using DTSC toxicity values, referred to as Method 2. This section summarizes both the Method 1 and Method 2 cancer risks and noncancer hazards for the RME scenario.

Tables H-7.1 through H-7.26; H-8.1 through H-8.26; and H-9.1 through H-9.26 provide the supporting calculations for the Method 1 and Method 2 cancer risks and HI estimates for the RME scenario (including background concentrations of metals) in formal RAGS Part D Standard Tables. Attachment H2 presents the risk estimate results in formal RAGS Part D Standard Tables for the CTE scenario for Method 1, and Attachment H3 presents the risk estimate results for the CTE scenario for Method 2. Attachment H4 presents the Method 1 and Method 2 incremental risks for the RME scenario (excluding background concentrations of metals).

In this discussion, a COPC is termed a "risk driver" when the COPC-specific cancer risk exceeds  $1 \times 10^{-6}$  or the COPC-specific HQ exceeds 1. For the commercial/industrial workers, construction workers, and residents, the HHRA evaluated risks assuming both minimal soil disturbance, in which exposures could occur only in the first 2 feet of soil, and intrusive soil development, in which exposures could occur within the first 4 feet of soil. For both the minimal disturbance and intrusive development scenarios, potential risks estimated for the vapor intrusion and groundwater exposure pathways are the same.

Section H8.1 presents the RME cancer risks, and Section H8.2 presents the RME noncancer HI estimates. Section H8.3 presents the results of the blood-lead modeling, and Section H8.4 presents the RME incremental risks (excluding background concentrations of metals). EPA guidance recommends presenting cancer risk and HI estimates to only one significant figure (EPA 1989). However, Tables H-7.1 through H-9.26 present chemical-specific risk results to two significant figures to aid review of the risk calculations. Likewise, this section discusses risks using two significant figures, so the discussion can be easily matched with the calculations presented in Tables H-7.1 through H-9.26.

## H8.1 CANCER RISK ESTIMATES

This section summarizes the RME cancer risks for future commercial/industrial workers, construction workers, residents, and recreational users at IR Site 34. The cancer risks presented in this section are total risk estimates (including background concentrations of metals) using both EPA toxicity values (Method 1) and DTSC toxicity values (Method 2). In this discussion, a COPC is termed a “risk driver” when the COPC-specific cancer risk exceeds  $1 \times 10^{-6}$ .

### H8.1.1 Future Commercial/Industrial Worker

The table below presents the exposure pathways and potential RME cancer risks for the future commercial/industrial worker. Tables H-7.1, H-7.2, H-7.14, and H-7.15 present the estimated RME risks for each COPC for the commercial/industrial worker in formal RAGS Part D Standard Tables.

Commercial/Industrial Worker Exposure Pathways	RME Cancer Risk Estimates (0 to 2 feet bgs)		RME Cancer Risk Estimates (0 to 4 feet bgs)	
	Method 1	Method 2	Method 1	Method 2
Soil Ingestion	1.3E-05	3.7E-05	1.3E-05	4.5E-05
Dermal Contact with Soil	1.5E-05	2.8E-05	1.3E-05	2.9E-05
Inhalation of Particulates and Volatiles Released from Soil to Outdoor Air	1.9E-06	7.4E-06	1.9E-06	7.4E-06
Inhalation of Volatiles Released from Soil to Indoor Air (vapor intrusion)	2.0E-05	1.9E-04	2.0E-05	1.9E-04
<b>Soil Total</b>	<b>4.9E-05</b>	<b>2.6E-04</b>	<b>4.8E-05</b>	<b>2.7E-04</b>
Inhalation of Volatiles Released from Groundwater to Outdoor Air	4.0E-08	3.9E-08	4.0E-08	3.9E-08
Inhalation of Volatiles Released from Groundwater to Indoor Air (vapor intrusion)	7.8E-07	8.2E-07	7.8E-07	8.2E-07
<b>Groundwater Total</b>	<b>8.2E-07</b>	<b>8.6E-07</b>	<b>8.2E-07</b>	<b>8.6E-07</b>
<b>Total Risk</b>	<b>5E-05</b>	<b>3E-04</b>	<b>5E-05</b>	<b>3E-04</b>

**Method 1 (EPA) Cancer Risk Estimates.** The total cancer risk from exposure to surface soil is  $4.9 \times 10^{-5}$  and from subsurface soil is  $4.8 \times 10^{-5}$ , which are within the  $10^{-4}$  and  $10^{-6}$  range. The total cancer risk from exposure to volatiles in groundwater is  $8.2 \times 10^{-7}$ . Cancer risk drivers in soil include 1,4-dichlorobenzene, Aroclor-1248, arsenic, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenz(a,h)anthracene.

**Method 2 (DTSC) Cancer Risk Estimates.** The total cancer risk from exposure to surface soil is  $2.6 \times 10^{-4}$  and from subsurface soil is  $2.7 \times 10^{-4}$ , which exceed the  $10^{-4}$  and  $10^{-6}$  range for carcinogens. The total cancer risk from exposure to volatiles in groundwater is  $8.6 \times 10^{-7}$ . Cancer risk drivers in soil include 1,4-dichlorobenzene, Aroclor-1248, arsenic, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, cadmium, dibenz(a,h)anthracene, and naphthalene.

The PAHs and metals identified as risk drivers using EPA (Method 1) and DTSC (Method 2) toxicity values were all detected in more than 40 percent of the samples, and the EPCs for these risk drivers are all based on the 95UCL. The other risk drivers, however, were all detected in less than 4 percent of the samples and the EPCs are based on the maximum detected concentrations. The detection frequencies for these less frequently detected risk drivers in soil samples collected from 0 to 4 feet bgs are 1 of 37 for 1,4-dichlorobenzene and 3 of 138 for Aroclor-1248 (see Table H-2.2). Detection limits for these risk drivers met project-required reporting limits listed in the RI Work Plan (SulTech 2006) and were less than EPA Region 9 PRGs (EPA 2004e).

One of the primary differences between the Method 1 and Method 2 results is due to naphthalene. Although Cal/EPA considers naphthalene to be carcinogenic, the EPA currently does not. The EPA IRIS (2007) website states for naphthalene:

Using the 1996 Proposed Guidelines for Carcinogen Risk Assessment, the human carcinogenic potential of naphthalene via the oral or inhalation routes "cannot be determined" at this time based on human and animal data; however, there is suggestive evidence (observations of benign respiratory tumors and one carcinoma in female mice only exposed to naphthalene by inhalation [NTP 1992a]). Additional support includes increase in respiratory tumors associated with exposure to 1-methylnaphthalene.

### H8.1.2 Future Construction Worker

The table below presents the exposure pathways and potential RME cancer risks for the future construction worker. Tables H-7.3, H-7.4, H-7.16, and H-7.17 present the estimated RME risks for each COPC for the construction worker in formal RAGS Part D Standard Tables.

Construction Worker Exposure Pathways	RME Cancer Risk Estimates (0 to 2 feet bgs)		RME Cancer Risk Estimates (0 to 4 feet bgs)	
	Method 1	Method 2	Method 1	Method 2
Soil Ingestion	1.7E-06	4.8E-06	1.7E-06	6.0E-06
Dermal Contact with Soil	2.3E-06	4.6E-06	2.2E-06	4.7E-06
Inhalation of Particulates and Volatiles Released from Soil to Outdoor Air	8.1E-07	1.4E-06	9.3E-07	1.5E-06
<b>Soil Total</b>	<b>4.8E-06</b>	<b>1.1E-05</b>	<b>4.8E-06</b>	<b>1.2E-05</b>
Inhalation of Volatiles Released from Groundwater to Outdoor Air	2.3E-09	2.2E-09	2.3E-09	2.2E-09
<b>Groundwater Total</b>	<b>2.3E-09</b>	<b>2.2E-09</b>	<b>2.3E-09</b>	<b>2.2E-09</b>
<b>Total Risk</b>	<b>5E-06</b>	<b>1E-05</b>	<b>5E-06</b>	<b>1E-05</b>

**Method 1 (EPA) Cancer Risk Estimates.** The total cancer risk from exposure to surface and subsurface soil is  $4.8 \times 10^{-6}$ , which is within the  $10^{-4}$  and  $10^{-6}$  range. The total cancer risk from exposure to volatiles in groundwater is  $2.3 \times 10^{-9}$ . Cancer risk drivers in soil include arsenic and benzo(a)pyrene.

**Method 2 (DTSC) Cancer Risk Estimates.** The total cancer risk from exposure to surface soil is  $1.1 \times 10^{-5}$  and from subsurface soil is  $1.2 \times 10^{-5}$ , which is within the  $10^{-4}$  and  $10^{-6}$  range for carcinogens. The total cancer risk from exposure to volatiles in groundwater is  $2.2 \times 10^{-9}$ . Cancer risk drivers in soil include arsenic and benzo(a)pyrene .

The PAHs and metals identified as risk drivers using EPA (Method 1) and DTSC (Method 2) toxicity values were all detected in more than 50 percent of the samples, and the EPCs for these risk drivers are all based on the 95UCL. Arsenic is considered to be above background concentrations based on two-population statistical tests (see Table 4-2 of the RI Report).

### H8.1.3 Future Resident

The table below presents the exposure pathways and potential RME cancer risks for the future resident. The potential cancer risks presented below for the child/adult resident are the combined potential cancer risks for the resident child and adult. Tables H-7.5 through H-7.10, and H-7.18 through H-7.23 present the estimated RME risks for each COPC for the future resident child and adult in formal RAGS Part D Standard Tables.

Resident Child/Adult Exposure Pathways	RME Cancer Risk Estimates (0 to 2 feet bgs)		RME Cancer Risk Estimates (0 to 4 feet bgs)	
	Method 1	Method 2	Method 1	Method 2
Soil Ingestion	5.7E-05	1.6E-04	5.9E-05	2.0E-04
Dermal Contact with Soil	1.9E-05	3.6E-05	1.7E-05	3.7E-05
Ingestion of Homegrown Produce	6.1E-05	5.0E-05 1.2E-04	5.7E-05	1.3E-04
Inhalation of Particulates and Volatiles Released from Soil to Outdoor Air	5.8E-06	2.2E-05	5.8E-06	2.2E-05
Inhalation of Volatiles Released from Soil to Indoor Air (vapor intrusion)	1.3E-04	1.4E-03	1.3E-04	1.4E-03
<b>Soil Total</b>	<b>2.8E-04</b>	<b>1.7E-03</b>	<b>2.7E-04</b>	<b>1.8E-03</b>
Inhalation of Volatiles Released from Groundwater to Outdoor Air	1.2E-07	1.2E-07	1.2E-07	1.2E-07
Inhalation of Volatiles Released from Groundwater to Indoor Air (vapor intrusion)	5.1E-06	5.9E-06	5.1E-06	5.9E-06
<b>Groundwater Total</b>	<b>5.2E-06</b>	<b>6.0E-06</b>	<b>5.2E-06</b>	<b>6.0E-06</b>
<b>Total Risk</b>	<b>3E-04</b>	<b>2E-03</b>	<b>3E-04</b>	<b>2E-03</b>

**Method 1 (EPA) Cancer Risk Estimates.** The total cancer risk from exposure to surface soil is  $2.8 \times 10^{-4}$  and from subsurface soil is  $2.7 \times 10^{-4}$ , which exceeds the  $10^{-4}$  and  $10^{-6}$  range. The total cancer risk from exposure to volatiles in groundwater is  $5.2 \times 10^{-6}$ . Trichloroethene via vapor intrusion was the only COPC in groundwater with a COPC-specific cancer risk greater than  $1 \times 10^{-6}$ . Cancer risk drivers in soil include 1,4-dichlorobenzene, 4-nitroaniline, Aroclor-1248, Aroclor-1254, Aroclor-1260, arsenic, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, bis(2-ethylhexyl)phthalate, dibenzo(a,h)anthracene, dieldrin, heptachlor epoxide, and indeno(1,2,3-cd)pyrene.

**Method 2 (DTSC) Cancer Risk Estimates.** The total cancer risk from exposure to surface soil is  $1.7 \times 10^{-3}$  and from subsurface soil is  $1.8 \times 10^{-3}$ , which exceeds the  $10^{-4}$  and  $10^{-6}$  range for carcinogens. The total cancer risk from exposure to volatiles in groundwater is  $6.0 \times 10^{-6}$ , which is within the risk  $10^{-4}$  and  $10^{-6}$  for carcinogens. Vinyl chloride was the only COPC in groundwater with a COPC-specific cancer risk greater than  $1 \times 10^{-6}$ . Vapor intrusion of vinyl chloride ( $5.2 \times 10^{-6}$ ) accounted for most of the cancer risk from groundwater. Cancer risk drivers in soil include 1,4-dichlorobenzene, 4-nitroaniline, Aroclor-1248, Aroclor-1254, Aroclor-1260, arsenic, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, cadmium, chrysene, dibenzo(a,h)anthracene, dieldrin, heptachlor epoxide, indeno(1,2,3-cd)pyrene, naphthalene, and technical chlordane.

The PAHs, metals, and two of the PCBs (Aroclor-1254 and Aroclor-1260) identified as risk drivers in soil using EPA (Method 1) and DTSC (Method 2) toxicity values were all detected in more than 25 percent of the samples, and the EPCs for these risk drivers are all based on the 95UCL. The EPCs for three of the pesticides identified as risk drivers (dieldrin, heptachlor epoxide, and technical chlordane) are based on the 95UCL. Dieldrin was detected in 14 of 90 soil samples, heptachlor epoxide in 13 of 90 soil samples, and technical chlordane in 4 of 75 soil samples collected from 0 to 4 feet bgs (see Table H-2.2). The other risk drivers were detected in less than 4 percent of the samples, and the EPCs are based on the maximum detected concentrations. The detection frequencies for the less frequently detected risk drivers in soil samples collected from 0 to 4 feet bgs are 1 of 37 for 1,4-dichlorobenzene, 1 of 35 for 4-nitroaniline, and 3 of 138 for Aroclor-1248 (see Table H-2.2).

TCE and vinyl chloride were the only risk drivers in groundwater. Vinyl chloride was only detected in 1 in 29 groundwater samples (see Table H-2.3). Vinyl chloride was detected in a groundwater sample collected using direct-push technologies, but was not detected in any of the monitoring wells. Trichloroethene was detected in 8 of 29 groundwater samples (see Table H-2.3). Trichloroethene was a risk driver using EPA toxicity values but not when using DTSC toxicity values. The HHRA used an EPA oral and inhalation SF of  $0.4 \text{ (mg/kg-day)}^{-1}$ , which is a provisional values from the National Center for Environmental Assessment as presented in the EPA Region 9 PRG table (EPA 2004e). OEHHA has established an oral SF of  $1.3 \times 10^{-2} \text{ (mg/kg-day)}^{-1}$  and an inhalation SF of  $7 \times 10^{-3} \text{ per (mg/kg-day)}^{-1}$ . EPA's SFs are more than an order of magnitude more conservative than DTSCs SFs. Section H9.3.3 further discusses uncertainties associated with trichloroethene toxicity values.

The vapor intrusion pathway contributed more than 45 percent to the potential cancer risks in soil and groundwater using EPA and DTSC toxicity values. Many of the exposure assumptions used to estimate risks from the indoor air pathway are highly conservative and may have overestimated risks to a resident in a hypothetical residence. The vapor intrusion models, for example, assumed steady-state concentrations of volatile COPCs in the subsurface for the entire duration of exposure (30 years for residents). It is much more likely that concentrations would decrease over time as chemicals move from one medium to another and from location to location within a particular medium. In addition, concentrations are likely to decrease as the chemical is lost through transformation or degradation processes, such as hydrolysis, photolysis, and

biodegradation. Section H9.0 provides additional detail on the uncertainties associated with risk estimates in this HHRA.

#### H8.1.4 Future Recreational User

The table below presents the exposure pathways and potential RME cancer risks for the future recreational user. The potential cancer risks presented below for the child/adult recreational user are the combined potential cancer risks for the recreational child and adult. Tables H-7.11 through H-7.13, and H-7.24 through H-7.26 present the estimated RME risks for each COPC for the future recreational child and adult in formal RAGS Part D Standard Tables. The HHRA evaluated risks for the future recreational user assuming minimal soil disturbance, in which exposures could occur only in the first 2 feet of soil.

Recreational Child/Adult Exposure Pathways	RME Cancer Risk Estimates (0 to 2 feet bgs)	
	Method 1	Method 2
Soil Ingestion	1.2E-05	3.5E-05
Dermal Contact with Soil	1.9E-05	3.6E-05
Inhalation of Particulates and Volatiles Released from Soil to Outdoor Air	7.1E-07	2.8E-06
<b>Soil Total</b>	<b>3.2E-05</b>	<b>7.4E-05</b>
Inhalation of Volatiles Released from Groundwater to Outdoor Air	1.5E-08	1.4E-08
<b>Groundwater Total</b>	<b>1.5E-08</b>	<b>1.4E-08</b>
<b>Total Risk</b>	<b>3E-05</b>	<b>7E-05</b>

**Method 1 (EPA) Cancer Risk Estimates.** The total cancer risk from exposure to surface soil is  $3.2 \times 10^{-5}$ , which is within the  $10^{-4}$  to  $1 \times 10^{-6}$  range for carcinogens. The total cancer risk from exposure to volatiles in groundwater is  $1.5 \times 10^{-8}$ , which is less than  $1 \times 10^{-6}$ . Cancer risk drivers in soil include Aroclor-1248, Aroclor-1260, arsenic, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and dibenzo(a,h)anthracene.

**Method 2 (DTSC) Cancer Risk Estimates.** The total cancer risk from exposure to surface soil is  $7.4 \times 10^{-5}$ , which is within the  $10^{-4}$  and  $10^{-6}$  for carcinogens. The total cancer risk from exposure to volatiles in groundwater is  $1.4 \times 10^{-8}$ . Cancer risk drivers in soil include Aroclor-1248, arsenic, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, and benzo(k)fluoranthene.

The PAHs and metals identified as risk drivers using EPA (Method 1) and DTSC (Method 2) toxicity values were all detected in more than 40 percent of the samples, and the EPCs for these risk drivers are all based on the 95UCL. Aroclor-1248, however, was only detected in 3 of 138 soil samples collected from 0 to 4 feet bgs (see Table H-2.2), and the EPC is based on the maximum detected concentration (see Table H-3.2).

## H8.2 NONCANCER HAZARD ESTIMATES

This section summarizes the RME HI estimates for future commercial/industrial workers, construction workers, residents, and recreational users at IR Site 34. The HI estimates presented in this section are total risk estimates (including background concentrations of metals) using both EPA toxicity values (Method 1) and DTSC toxicity values (Method 2). Noncancer HIs are evaluated in conjunction with the threshold of 1 for noncarcinogens. A target organ analysis is only conducted if the noncancer HI is greater than 1 and there are no COPC-specific HQs exceeding 1; otherwise, a target organ analysis would not further characterize the health hazard.

### H8.2.1 Future Commercial/Industrial Worker

The table below presents the exposure pathways and potential RME HI estimates for the future commercial/industrial worker. Tables H-7.1, H-7.2, H-7.14, and H-7.15 present the estimated RME risks for each COPC for the commercial/industrial worker in formal RAGS Part D Standard Tables.

Commercial/Industrial Worker Exposure Pathways	RME HI (0 to 2 feet bgs)		RME HI (0 to 4 feet bgs)	
	Method 1	Method 2	Method 1	Method 2
Soil Ingestion	0.38	0.37	0.36	0.36
Dermal Contact with Soil	0.19	0.19	0.19	0.19
Inhalation of Particulates and Volatiles Released from Soil to Outdoor Air	0.20	0.20	0.20	0.20
Inhalation of Volatiles Released from Soil to Indoor Air (vapor intrusion)	6.6	6.6	6.6	6.6
<b>Soil Total</b>	<b>7.4</b>	<b>7.4</b>	<b>7.4</b>	<b>7.4</b>
Inhalation of Volatiles Released from Groundwater to Outdoor Air	0.00033	0.00030	0.00033	0.00030
Inhalation of Volatiles Released from Groundwater to Indoor Air (vapor intrusion)	0.0067	0.0061	0.0067	0.0061
<b>Groundwater Total</b>	<b>0.0071</b>	<b>0.0064</b>	<b>0.0071</b>	<b>0.0064</b>
<b>Total Risk</b>	<b>7</b>	<b>7</b>	<b>7</b>	<b>7</b>

**Method 1 (EPA) and Method 2 (DTSC) Noncancer HI Estimates.** For both the Method 1 and Method 2 HI estimates, the total HI from exposure to surface and subsurface soil is 7.4, which is greater than the threshold HI of 1 for noncarcinogens. The HI from exposure to groundwater is less than 1 using both EPA (Method 1) and DTSC (Method 2) toxicity values. Vapor intrusion of naphthalene (4.2) and 1,2,4-trichlorobenzene (1.7) accounts for most of the HI. Naphthalene and 1,2,4-Trichlorobenzene are the only hazard drivers with a COPC-specific HQ exceeding 1. The EPCs for naphthalene and 1,2,4-trichlorobenzene are based on the maximum detected concentration. Naphthalene was only detected in 2 of 37 soil samples collected from 0 to 4 feet bgs and 1,2,4-trichlorobenzene was only detected in 1 of 37 soil samples collected from 0 to 4 feet bgs (see Table H-2.2).

## H8.2.2 Future Construction Worker

The table below presents the exposure pathways and potential RME HI estimates for the future construction worker. Tables H-7.3, H-7.4, H-7.16, and H-7.17 present the estimated RME risks for each COPC for the construction worker in formal RAGS Part D Standard Tables.

Construction Worker Exposure Pathways	RME HI (0 to 2 feet bgs)		RME HI (0 to 4 feet bgs)	
	Method 1	Method 2	Method 1	Method 2
Soil Ingestion	1.2	1.2	1.2	1.2
Dermal Contact with Soil	0.76	0.76	0.75	0.75
Inhalation of Particulates and Volatiles Released from Soil to Outdoor Air	6.4	7.4	6.1	7.1
<b>Soil Total</b>	<b>8.4</b>	<b>9.4</b>	<b>8.0</b>	<b>9.1</b>
Inhalation of Volatiles Released from Groundwater to Outdoor Air	0.00047	0.00043	0.00047	0.00043
<b>Groundwater Total</b>	<b>0.00047</b>	<b>0.00043</b>	<b>0.00047</b>	<b>0.00043</b>
<b>Total Risk</b>	<b>8</b>	<b>9</b>	<b>8</b>	<b>9</b>

**Method 1 (EPA) Noncancer HI Estimates.** The total HI from exposure to surface soil is 8.4 and from exposure to subsurface soil is 8.0, which are both greater than the threshold HI of 1 for noncarcinogens. The total HI from exposure to volatile chemicals in groundwater is 0.00047, which is less than the threshold HI of 1 for noncarcinogens. The HQ from exposure to subsurface soil (0 to 4 feet bgs) is 1.3 for aluminum and 4.2 for manganese. COPCs with an HQ of less than 1 contribute to the rest of the total HI of 8. Aluminum and manganese in soil are the only risk drivers with a COPC-specific HQ exceeding 1. Inhalation of fugitive dust by a future construction worker accounts for more than 85 percent of the total HI of aluminum and manganese.

**Method 2 (DTSC) Noncancer HI Estimates.** The total HI from exposure to surface soil is 9.4 and from exposure to subsurface soil is 9.1, which are both greater than the threshold HI of 1 for noncarcinogens. The total HI from exposure to volatile chemicals in groundwater is 0.00043, which is less than the threshold HI of 1 for noncarcinogens. Aluminum and manganese in soil are the only risk drivers with a COPC-specific HQ exceeding 1. The HQ from exposure to subsurface soil (0 to 4 feet bgs) is 1.2 for aluminum and 4.2 for manganese.

Aluminum and manganese were both detected in all 71 soil samples collected from 0 to 4 feet bgs (see Table H-2.2). Two-population statistical tests determined that these metals are present above background concentrations (see Table 4-2 of the RI Report). The RfD for aluminum is based on a provisional value developed by EPA's National Center of Environmental Assessment for the Superfund program (EPA 2004d). Provisional values do not receive the same multiprogram consensus review provided by the IRIS program. Section H-9.0 provides additional detail on the uncertainties associated with risk estimates in this HHRA.

### H8.2.3 Future Resident

The table below presents the exposure pathways and potential RME HI estimates for the future resident. The potential HI estimates presented below for the child/adult resident are those estimated for the child receptor because HIs are higher for child residents than those estimated for the adult. Tables H-7.5 through H-7.10, and H-7.18 through H-7.23 present the estimated RME risks for each COPC for the future resident child and adult in formal RAGS Part D Standard Tables.

Resident Child/Adult Exposure Pathways	RME HI (0 to 2 feet bgs)		RME HI (0 to 4 feet bgs)	
	Method 1	Method 2	Method 1	Method 2
Soil Ingestion	4.9	4.9	4.8	4.7
Dermal Contact with Soil	0.63	0.63	0.62	0.62
Ingestion of Homegrown Produce	2.1	2.1	1.9	1.9
Inhalation of Particulates and Volatiles Released from Soil to Outdoor Air	0.96	0.96	0.96	0.96
Inhalation of Volatiles Released from Soil to Indoor Air (vapor intrusion)	74	74	74	74
<b>Soil Total</b>	<b>82</b>	<b>82</b>	<b>82</b>	<b>82</b>
Inhalation of Volatiles Released from Groundwater to Outdoor Air	0.0015	0.0014	0.0015	0.0014
Inhalation of Volatiles Released from Groundwater to Indoor Air (vapor intrusion)	0.064	0.058	0.064	0.058
<b>Groundwater Total</b>	<b>0.065</b>	<b>0.059</b>	<b>0.065</b>	<b>0.059</b>
<b>Total Risk</b>	<b>82</b>	<b>82</b>	<b>82</b>	<b>82</b>

**Method 1 (EPA) and Method 2 Noncancer HI Estimates.** Using both the EPA and DTSC toxicity values, the total HI from exposure to surface and subsurface soil is 82, which is greater than the threshold HI of 1 for noncarcinogens. The HI from exposure to groundwater is less than 1 using both EPA (Method 1) and DTSC (Method 2) toxicity values. Hazard risk drivers in soil include 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-dichlorobenzene, Aroclor-1248, iron, and naphthalene. The four VOCs (1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, 1,2-dichlorobenzene) were all detected only once and at the same location (DP2). Vapor intrusion of 1,2,4-trichlorobenzene (18) and naphthalene (47) accounts for more than 85 percent of the estimated HI. 1,2,4-Trichlorobenzene was only detected in 1 of 37 soil samples collected from 0 to 4 feet bgs and naphthalene was only detected in 2 of 37 soil samples collected from 0 to 4 feet bgs (see Table H-2.2). Aroclor-1248 was only detected in 3 of 138 soil samples collected from 0 to 4 feet bgs.

Iron was detected in all 71 soil samples. Although both EPA (1989) and DTSC (1992) classify iron as an essential nutrient, it has been shown to be toxic at high doses, thus iron was considered for COPC selection in this HHRA. The EPA Region 9 PRGs for iron were derived from a provisional reference RfD developed by National Center for Environmental Assessment in 1996 for a specific metabolic disorder (EPA 2004e). Incorporation of this reference dose into the

characterization of noncancer hazards resulted in a chemical-specific HQ exceeding 1. The significance of these results is dubious because ongoing debate over this provisional reference dose has not resulted in its incorporation into IRIS (EPA 2007). Section H-9.0 provides additional detail on the uncertainties associated with risk estimates in this HHRA.

### H8.2.4 Future Recreational User

The table below presents the exposure pathways and potential RME HI estimates for the future recreational user. The potential HI estimates presented below for the child/adult recreational user are those estimated for the child receptor because HIs are higher for child residents than those estimated for the adult. Tables H-7.11 through H-7.13, and H-7.24 through H-7.26 present the estimated RME risks for each COPC for the future recreational child and adult in formal RAGS Part D Standard Tables. The HHRA evaluated risks for the future recreational user assuming minimal soil disturbance, in which exposures could occur only in the first 2 feet of soil.

Recreational Child/Adult Exposure Pathways	RME HI (0 to 2 feet bgs)	
	Method 1	Method 2
Soil Ingestion	1.1	1.0
Dermal Contact with Soil	0.63	0.63
Inhalation of Particulates and Volatiles Released from Soil to Outdoor Air	0.040	0.040
<b>Soil Total</b>	<b>1.7</b>	<b>1.7</b>
Inhalation of Volatiles Released from Groundwater to Outdoor Air	0.000064	0.000059
<b>Groundwater Total</b>	<b>0.000064</b>	<b>0.000059</b>
<b>Total Risk</b>	<b>2</b>	<b>2</b>

**Method 1 (EPA) and Method 2 Noncancer HI Estimates.** Using both the EPA (Method 1) and DTSC (Method 2) toxicity values, the total HI from exposure to surface soil is 1.7, which is greater than the threshold HI of 1 for noncarcinogens. The HI from exposure to groundwater is less than 1 using EPA (Method 1) and DTSC (Method 2) toxicity values. Although the total HI is greater than the noncancer hazard threshold of 1 for exposure to surface soil, there are no chemicals with a calculated individual HI greater than 1. Thus, there are no noncancer risk drivers identified for the recreational user.

### H8.3 LEAD RESULTS

The potential for human health effects caused by lead is typically estimated on the basis of blood-lead concentrations. The table below presents the estimated blood-lead concentrations.

Exposure Area	Lead EPC (mg/kg)	Predicted 99th Percentile Blood-Lead Concentration (µg/dL)	
		Adult Resident	Child Resident
Surface Soil (0 to 2 feet bgs)	2,900	29.5	111

Subsurface Soil (0 to 4 feet bgs)	2,390	24.5	92
-----------------------------------	-------	------	----

Blood-lead modeling resulted in 99th percentile concentrations greater than 10 µg/dL for the adult and child residents. Because blood-lead modeling results exceed 10 µg/dL there is a potential for unacceptable deleterious effects from exposure to lead. Tables H-10.1 and H-10.2 present the blood-lead modeling results in DTSC LeadSpread templates.

Lead was detected in 92 of 94 soil samples collected from 0 to 4 feet bgs (see Table H-2.2). Two-population statistical tests determined that lead is greater than background concentrations (see Table 4-2 of the RI Report). Lead concentrations were greater than the background concentration of 24 mg/kg in 51 soil samples. Lead concentrations ranged from 2.1 mg/kg to 21,000 mg/kg and the average was 566 mg/kg. Lead concentrations exceeded the California-modified residential PRG of 150 mg/kg in 29 soil samples and the EPA industrial PRG of 800 mg/kg in seven soil samples.

#### **H8.4 INCREMENTAL RISKS**

Two-population statistical tests were used to compare metals concentrations in IR Site 34 soil samples with background concentrations determined for Alameda Point. Appendix G of the RI Report describes the background comparison procedures in greater detail. Statistical tests determined that beryllium, mercury, and silver are less than background concentrations and that all other detected metals are greater than background concentrations. To evaluate the contribution of background risks to the total risk estimates, the HHRA estimated incremental risks by calculating the risks from background concentrations of metals in soil and subtracting the background risks from the total risk estimates. Attachment H4 presents the incremental risks. Except for the construction worker, the incremental risks were identical to the total risks. Subtracting the contribution of background concentrations of manganese and chromium reduced the risks for the construction worker. However, the incremental cancer risk was still within the  $10^{-4}$  and  $10^{-6}$  range, and noncancer HI estimate is still greater than the threshold HI of 1 for noncarcinogens.

#### **H9.0 UNCERTAINTY ANALYSIS**

Varying degrees of uncertainty at each stage of the HHRA arise from assumptions made in the risk assessment and the limitations of the data used to calculate risks. Uncertainty and variability also are inherent in the exposure assessment, toxicity values, and risk characterization. The uncertainties fall into two categories: uncertainties associated with the general risk assessment methodologies, and site-specific uncertainties associated with this HHRA. The following subsections further discuss these uncertainties.

The effect of these uncertainties is to overestimate or underestimate the actual cancer risk or HI, depending on the specific factor. In general, the risk assessment process uses conservative (health-protective) assumptions that, when combined, are intended to overestimate the actual risk.

## **H9.1 DATA EVALUATION AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN**

The adequacy of site characterization data was reviewed and a structured COPC selection process was used to identify COPCs for the HHRA. Selecting representative sampling locations and collecting a sufficient number of samples determines the success of characterizing a contaminated site. The primary uncertainty associated with the COPC selection process is the possibility that a chemical may be inappropriately selected or excluded as a COPC in the risk assessment. The HHRA only excluded a chemical as a COPC when (1) a chemical was not detected, and (2) a metal is considered an essential nutrient (such as calcium, magnesium, potassium, and sodium). In addition, based on the CSM for IR Site 34 and the potentially complete exposure pathways identified in Section H5.3, this HHRA only identified a chemical considered to be volatile as a COPC in groundwater. Overall, this was a conservative approach that resulted in 50 COPCs in groundwater and more than 80 COPCs in soil.

## **H9.2 EXPOSURE ASSESSMENT**

Uncertainties were identified in association with four areas of the exposure assessment process: (1) the selection of exposure scenarios, (2) the selection of exposure pathways, (3) the estimation of EPCs, and (4) the selection of exposure variables used to estimate chemical intake. The following sections discuss uncertainties associated with each of these areas.

### **H9.2.1 Exposure Scenarios**

IR Site 34 is currently unoccupied land. The planned reuse of this area is recreational and includes the development of a golf course. Although future development of IR Site 34 for commercial/industrial or residential use may be unlikely, the HHRA evaluated these scenarios to provide alternative risk estimates for unrestricted reuse of the site and to support risk management decisions for the site. Construction workers are potential receptors if the site is redeveloped.

### **H9.2.2 Selecting Exposure Pathways**

The exposure pathways quantified in this HHRA were identified on the basis of the CSM, relevant site characterization data, and chemical fate and transport considerations. Uncertainty is introduced into the exposure assessment to the extent that these factors may not accurately predict the migration of chemicals within and from the area. For example, the vapor intrusion pathway assumes buildings will be constructed on a concrete slab and cracks in the floor or the walls will allow vapor intrusion of VOCs into homes or businesses.

### **H9.2.3 Estimating Exposure Point Concentrations**

For many sampling locations, the collection of samples was biased toward areas with known or suspected contamination, rather than collecting samples at equidistant intervals throughout the site. EPCs based on these biased soil and groundwater samples are likely to overestimate the

concentrations at the exposure point. In addition, the maximum detected concentrations were used as EPCs for data sets with fewer than four detected concentrations. For example, five of the VOCs (1,4-dichlorobenzene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, 1,2,4-trimethylbenzene, and 1,2-dichlorobenzene) that are risk drivers for the residential scenario were detected only once and at the same location (DP2). This may overestimate the risks because the HHRA assumes a potential receptor will be exposed to all localized hot spots even though the maximum detected concentrations are not all collocated.

#### **H9.2.4 Selecting Exposure Variables**

Most of the exposure variables used to estimate chemical intake are standard EPA default upper-bound estimates. Default exposure parameters are intended to be conservative so human health risks are not under-predicted. In general, considerable variation may occur in the activity patterns and physiological response of individuals. It is possible that the exposure variables used in this evaluation do not represent actual exposure conditions.

Variability in exposure duration and frequency, as well as breathing rates, soil ingestion rates, and amount of dermal contact with soil, can be substantial. In this risk assessment, RME scenarios were characterized for each receptor, which adds to the conservative assumptions that likely overestimate risk. Many of the default exposure parameters were selected to be representative of the 95 percentile level of exposure or higher for each exposure pathway, but they do not necessarily denote likely exposure. For example, it is unlikely that a 95 percentile level of exposure would occur concurrently for all of the potentially complete exposure pathways combined.

Variability of exposure assumptions can affect the results of a risk assessment. In this risk assessment, exposure assumptions were based on several sources, including the EPA (1997) "Exposure Factors Handbook" that provides recommended exposure assumptions for receptors of all ages. However, the EPA more recently released an external review draft of the "Child-Specific Exposure Factors Handbook [Child EFH]" (EPA 2006b) that presents exposure assumptions specific to children between 0 and 21 years old. Because the handbook is in the draft (external review) stage of development, the assumptions recommended in the Child EFH (EPA 2006b) were not used in this HHRA. When the Child EFH is finalized, exposure assumptions provided in the Child EFH will replace several child-specific assumptions used in this HHRA, which are based on EPA's (1997) "Exposure Factors Handbook".

This child exposure factor uncertainty analysis compared the exposure assumptions presented in the Child EFH (EPA 2006b) to the assumptions listed in EPA's (1997) "Exposure Factors Handbook." This risk assessment used two exposure assumptions for the child resident from EPA (1997): child produce intake rate of homegrown fruits and vegetables and the child inhalation rate. The HHRA estimated risks for RME and CTE scenarios; thus, exposure assumptions such as produce intake or inhalation rates were based on an RME (95<sup>th</sup> percentile) or CTE (50<sup>th</sup> percentile) scenario. To compare the differences between exposure assumptions used for evaluating child consumption of homegrown produce, an age-weighted homegrown produce intake rate (in units of grams per kilogram per day [g/kg-day]) was first calculated based

on Table 3-47 of EPA (2006b) for an RME (95<sup>th</sup> percentile) and CTE (50<sup>th</sup> percentile) scenario for a child aged 1 to 6 years old. The age-weighted average produce intake rate was then adjusted using equation 3-3 and Table 3-48 of the Child EFH (EPA 2006b) to determine the actual amount of homegrown produce consumed after cooking, preparation, and post-cooking losses. The produce intake rate was then multiplied by the weight of a child (15 kg) and a weight conversion factor (1E-03) to calculate the amount of produce consumed by a child in a day (kg/day). A comparison of the RME child produce intake rate from EPA (1997) to the rate derived from the draft Child EFH (EPA 2006b) shows that the produce intake rate would increase by a factor of 20.5 (0.0174 kg/day to 0.357 kg/day). The increase translates to an increase in the cancer risk and noncancer hazard for a residential child by a factor of 20.5 for the homegrown produce ingestion pathway. Using the draft Child EFH (EPA 2006b) produce intake rate, the risk associated with residential consumption of homegrown produce would exceed the risk management range of 1E-06 to 1E-04 (risks calculated using produce intake rates based on EPA [1997] were within the risk management range) and the noncancer hazard would continue to exceed 1.0. For the CTE scenario (50<sup>th</sup> percentile), the child produce intake rate would increase by a factor of 6.3 (0.0064 kg/day to 0.040 kg/day). The increase translates to an increase in the cancer risks and noncancer hazard for a residential child by a factor of 6.3. Using the Child EFH (EPA 2006b) produce intake rate, the risk associated with residential consumption of homegrown produce would continue to be within the risk management range of 1E-06 to 1E-04 and the noncancer hazard would continue to exceed 1.0.

To compare the differences between exposure assumptions used for evaluating the inhalation rate of a child, an age-weighted average inhalation rate (in units of m<sup>3</sup>/day) was calculated for a child aged 0 to 6 years old from rates presented in Table 7-17 (males) and Table 7-18 (females) of the Child EFH (EPA 2006b) for an RME (95<sup>th</sup> percentile) and CTE (50<sup>th</sup> percentile) scenario. The age-weighted average inhalation rates derived for males and females were averaged to determine a non-gender-specific inhalation rate. A comparison of the RME child inhalation rate from EPA (1997) to the rate derived from the draft Child EFH (EPA 2006b) shows that the child inhalation rate would increase by a factor of 1.54 (0.42 m<sup>3</sup>/hr to 0.645 m<sup>3</sup>/hr). The increase translates to an increase in the inhalation cancer risk and noncancer hazard for a residential child by a factor of 1.54. Using the draft Child EFH (EPA 2006b) inhalation rate, the risk associated with child inhalation pathways would continue to exceed both the risk management range of 1E-06 to 1E-04 and the noncancer hazard threshold of 1.0. For the CTE scenario, the child inhalation rate would increase by a factor of 1.5 (from 0.33 m<sup>3</sup>/hr to 0.495 m<sup>3</sup>/hr). The increase translates to an increase in the inhalation cancer risk and noncancer hazard for a residential child by a factor of 1.5. Using the draft Child EFH (EPA 2006b) inhalation rate, the risk associated with child inhalation pathways would continue to be within the risk management range of 1E-06 to 1E-04 and would continue to exceed the noncancer hazard threshold of 1.0.

## **H9.2.5 Applying the Vapor Intrusion Model**

This HHRA used the EPA's advanced vapor intrusion models for soil (EPA 2004a) and groundwater (EPA 2004b) to estimate indoor air concentrations from concentrations of volatile COPCs in soil and groundwater. These advanced versions, based on Johnson and Ettinger (1991), present more rigorous estimates by using site-specific input parameters. Exposure

assumptions used in the vapor intrusion model are conservative and may overestimate risks. For example, the HHRA used the maximum detected concentrations for many VOCs as EPCs, and assumed that a future building would be constructed at the location where the maximum concentrations of volatile COPCs in soil and groundwater were detected and that exposure to all volatile COPCs from vapor intrusion occurs concurrently, even though maximum concentrations are not collocated. In addition, the vapor intrusion models assumed steady-state concentrations of volatile COPCs in the subsurface for the entire duration of exposure (25 years for commercial/industrial workers and 30 years for residents). The assumption of steady-state concentrations for extended durations is conservative because, over time, chemicals may migrate from one medium to another or from one location to another within a particular medium. In addition, the assumption of steady-state concentrations for the entire duration of exposure assumes that reductions in concentrations that would likely occur through transformation or degradation processes—such as hydrolysis, photolysis, and biodegradation—do not occur. Evans and Bedient (1995) concluded that the use of steady-state methods may over predict risk by as much as two orders of magnitude.

Use of hypothetical building parameters in the vapor intrusion model may result in an overestimation of vapor emissions and higher indoor air concentrations because default building parameters tend to be conservative to ensure protection of all exposure scenarios. The assumption that buildings are continuously underpressurized neglects significant periods where neutral or positively pressurized conditions exist, thereby overestimating advective transport of contaminated vapors to indoor air and yielding higher indoor air concentrations.

### **H9.3 TOXICITY ASSESSMENT**

The primary uncertainties associated with the toxicity assessment are related to derivation of toxicity values for COPCs. Standard RfDs and SFs developed by EPA were used to estimate potential cancer and noncancer health effects from exposure to COPCs at the site. These values are derived by applying conservative (health-protective) assumptions and are intended to protect the most sensitive potentially exposed individuals.

EPA makes several assumptions to derive the toxicity values that tend to overestimate the actual risk or hazard to human health. The RfDs are typically derived from animal studies because data from human studies are generally unavailable. Uncertainty factors and modifying factors are then applied to the data from animal studies to ensure the RfDs are adequately protective of human health. This approach is anticipated to result in an overestimated potential for noncancer adverse health effects for many chemicals.

SFs used to estimate cancer risk also are typically derived based on data from animal studies. These data are from studies in which high doses of a test chemical were administered to laboratory animals, and the reported response is extrapolated to the much lower doses to which humans are likely to be subjected. Few experimental data are available on the nature of the dose-response relationship at low doses. (For example, a threshold may exist or the dose-response curve may pass through the origin.) Because of this uncertainty, EPA has selected a conservative model to estimate the low-dose relationship and uses an upper-bound estimate

(typically a 95UCL of the slope predicted by the extrapolation model) as the SF. An upper-bound estimate of potential cancer risks is obtained with this SF.

Route-to-route extrapolations were made for organic COPCs for which a SF or an RfD was available for only one route of exposure. These extrapolations will introduce some uncertainty into the risk and hazard estimates.

### **H9.3.1 Chemical Surrogates for Toxicity Criteria**

Tables H-6.1 through H-6.8 identify chemical surrogates used to evaluate chemicals that lack toxicity criteria. Since the relative toxicity of the chemical surrogates compared with the COPCs they represent is unknown, the degree of uncertainty contributed by the use of chemical surrogates is likewise unknown. Although selection and use of chemical surrogates for toxicity criteria adds uncertainty to the risk assessment, a lack of a toxicity criterion would otherwise remain a data gap. The surrogates selected for use in the HHRA were all closely structurally related to the COPCs that they were chosen to represent. Thus, the use of chemical surrogates may under- or overestimate risk.

### **H9.3.2 Provisional Peer-Reviewed Toxicity Values**

The EPA's National Center of Environmental Assessment has developed PPRTVs for chemicals that lack toxicity values (EPA 2004f). These values do not receive the same multi-program consensus review provided by the IRIS program; as a result, more uncertainty is associated with these values compared with the toxicity values provided in IRIS. Tables H-6.1 through H-6.8 identify the chemicals based on PPRTVs for chemicals that lack toxicity values (EPA 2004f). This includes COPCs identified as risk drivers such as 1,2,4-trimethylbenzene and aluminum.

### **H9.3.3 Trichloroethene**

Trichloroethene was a cancer risk driver using EPA toxicity values but not when using DTSC toxicity values. The EPA SFs used in the risk assessment for trichloroethene are more than an order of magnitude more conservative than DTSC SFs for trichloroethene. DTSC has established an oral SF of  $1.3 \times 10^{-2} \text{ (mg/kg-day)}^{-1}$  and an inhalation SF of  $7 \times 10^{-3} \text{ per (mg/kg-day)}^{-1}$ . This risk assessment used an EPA oral and inhalation SF of  $0.4 \text{ (mg/kg-day)}^{-1}$ , which is a provisional values from the National Center for Environmental Assessment as presented in the EPA Region 9 PRG table (EPA 2004e). EPA withdrew its previously published toxicity values from EPA's IRIS database in 1988 and has not published finalized toxicity values for trichloroethene since the original values were withdrawn because of uncertainties relating to the science of trichloroethene toxicity. In 2001, EPA's Office of Research and Development completed a preliminary draft reassessment of health risks posed by trichloroethene (EPA 2001a). This preliminary draft reassessment proposes toxicity values that are much more conservative than the values withdrawn by EPA, and these suggested toxicity values are now the subject of much debate. As such, the scientific community is divided on whether to use the withdrawn values, the new suggested values, or some other values for calculating risks. EPA's

National Center for Environmental Assessment has recommended several SFs for trichloroethene, with most between  $2 \times 10^{-2}$  and  $4 \times 10^{-1}$  per mg/kg-day. The range of SFs has not been reduced to a single number, but EPA's National Center for Environmental Assessment recommends that risk assessors use the upper-end of the SF range (that is,  $4 \times 10^{-1}$  per mg/kg-day) to emphasize the possibility that different risks may exist under different circumstances. The use of the upper end of the range of SFs is conservative and may result in an overestimation of risks.

#### **H9.4 RISK CHARACTERIZATION**

Standard EPA methods estimate the total cancer risk associated with a site by adding the exposure risks for multiple carcinogens. According to EPA guidance (EPA 1989),

“...uncertainties associated with summing risks or hazard indices for several substances are of particular concern in the risk characterization step. The assumption of dose additivity ignores possible synergisms or antagonisms among chemicals, and assumes similarity in mechanisms of action and metabolism. Unfortunately, data to assess interactions quantitatively are lacking.”

Despite these concerns, EPA guidance recommends summing the risks and HIs to avoid underestimating cancer risk or potential noncancer health effects at a site (EPA 1989). Summing the risks and HIs may overestimate results because mechanisms of action and metabolism are assumed to be similar and potential antagonistic effects are ignored. It also is possible that total risks and HIs may be underestimated because potential synergistic effects are ignored.

**Construction Workers, Residents, Commercial/Industrial Workers, and Recreational Users**  
Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population (a)	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway			
Current	All	All	All	All	All	All	None	There are no current residential, commercial/industrial, construction worker, or recreational receptors at Site 34.			
Future	Surface Soil (0 to 2 ft bgs)	Surface Soil	Surface Soil	Resident	Adult	Ingestion	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.			
						Dermal Absorption	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.			
					Child	Ingestion	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.			
						Dermal Absorption	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.			
					Commercial/Industrial Worker	Ingestion	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.			
						Dermal Absorption	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.			
				Construction Worker	Ingestion	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.				
					Dermal Absorption	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.				
				Recreational User	Adult	Ingestion	Quant.	The most likely future land use at the site is a golf course. This exposure pathway would be potentially complete for a golfer.			
						Dermal Absorption	Quant.	The most likely future land use at the site is a golf course. This exposure pathway would be potentially complete for a golfer.			
					Child	Ingestion	Quant.	If the site is redeveloped for recreational use, this exposure pathway would be potentially complete.			
						Dermal Absorption	Quant.	If the site is redeveloped for recreational use, this exposure pathway would be potentially complete.			
					Homegrown Produce	Ingestion	Quant.	Under a redevelopment scenario, this exposure pathway would be complete.			
						Dermal Absorption	Quant.	Under a redevelopment scenario, this exposure pathway would be complete.			
				Particulates and Vapors	Respirable Particulates Suspended from Surface Soil and VOCs in Outdoor Air	Resident	Adult	Inhalation	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.	
								Child	Inhalation	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.
						Commercial/Industrial Worker	Adult		Inhalation	Quant.	Under a redevelopment scenario with minimal surface regrading, this exposure pathway would be complete.
								Construction Worker	Adult	Inhalation	Quant.
	Recreational User	Adult	Inhalation			Quant.	The most likely future land use at the site is a golf course. This exposure pathway would be potentially complete for a golfer.				
			Child			Inhalation	Quant.	If the site is redeveloped for recreational use, this exposure pathway would be potentially complete.			
	Subsurface Soil (0 to 4 ft bgs)	Subsurface Soil					Combined Surface and Subsurface Soil	Resident	Adult	Ingestion	Quant.
			Child			Ingestion				Quant.	Under a redevelopment scenario with significant surface regrading, this exposure pathway would be complete.
						Commercial/Industrial Worker			Adult	Dermal Absorption	Quant.
			Construction Worker							Adult	Dermal Absorption
				Recreational User	Adult	Ingestion			None		The most likely future land use at the site is a golf course. This exposure pathway is not considered complete because recreational use is not considered an intrusive pathway that will expose golfers to subsurface soils more than 2 feet bgs.
			Child			Ingestion			None	The most likely future land use at the site is a golf course. This exposure pathway is not considered complete because recreational use is not considered an intrusive pathway that will expose golfers to subsurface soils more than 2 feet bgs.	
				Recreational User	Adult			Dermal Absorption	None	The most likely future land use at the site is a golf course. This exposure pathway is not considered complete because recreational use is not considered an intrusive pathway that will expose golfers to subsurface soils more than 2 feet bgs.	
			Child			Dermal Absorption		None	The most likely future land use at the site is a golf course. This exposure pathway is not considered complete because recreational use is not considered an intrusive pathway that will expose golfers to subsurface soils more than 2 feet bgs.		
Homegrown Produce				Resident	Adult			Ingestion	Quant.	Under a redevelopment scenario, this exposure pathway would be complete.	
			Child			Ingestion		Quant.	Under a redevelopment scenario, this exposure pathway would be complete.		

**TABLE H-1: EPA RAGS PART D TABLE 1, SELECTION OF EXPOSURE PATHWAYS**  
**Construction Workers, Residents, Commercial/Industrial Workers, and Recreational Users (continued)**  
Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population (a)	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway	
Future (continued)	Subsurface Soil (0 to 4 ft bgs) (continued)	Particulates and Vapors	Respirable Particulates Suspended from Surface Soil and VOCs in Outdoor Air	Resident	Adult	Inhalation	Quant.	Under a redevelopment scenario with significant surface regrading, this exposure pathway would be complete.	
					Child	Inhalation	Quant.	Under a redevelopment scenario with significant surface regrading, this exposure pathway would be complete.	
				Commercial/Industrial Worker	Adult	Inhalation	Quant.	Under a redevelopment scenario with significant surface regrading, this exposure pathway would be complete.	
				Construction Worker	Adult	Inhalation	Quant.	Under a redevelopment scenario with significant surface regrading, this exposure pathway would be complete.	
				Recreational User	Adult	Inhalation	Quant.	The most likely future land use at the site is a golf course. This exposure pathway would be potentially complete for a golfer.	
					Child	Inhalation	Quant.	If the site is redeveloped for recreational use, this exposure pathway would be potentially complete.	
		Vapors	Vapors from Subsurface Soil to Indoor Air via Vapor Intrusion	Resident	Adult	Inhalation	Quant.	If the site is ever developed for residential use, volatile compounds in soil could migrate into indoor air thus making this exposure pathway complete.	
					Child	Inhalation	Quant.	If the site is ever developed for residential use, volatile compounds in soil could migrate into indoor air thus making this exposure pathway complete.	
				Commercial/Industrial Worker	Adult	Inhalation	Quant.	If the site is ever developed for industrial use, volatile compounds in soil may migrate into indoor air making this pathway complete.	
				Construction Worker	Adult	Inhalation	None	Construction Workers are considered only outdoor receptors.	
				Recreational User	Adult	Inhalation	None	Recreational Users are considered only outdoor receptors.	
					Child	Inhalation	None	Recreational Users are considered only outdoor receptors.	
Future	Groundwater	Groundwater	Shallow Groundwater	Construction Worker	Adult	Dermal Contact	None	Although it is acknowledged that construction workers may also contact groundwater dermally during excavation activities that intercept the shallow water table (located at about 4 feet bgs across the site), construction in saturated trench conditions is generally avoided and dewatering is quickly implemented for effective construction activities. Therefore, groundwater-related pathways of exposure for a construction worker are potentially complete, but are expected to be quantitatively negligible relative to all other pathways, and will not be quantitatively evaluated in the HHRA for Site 34.	
			Tap Water from Shallow Groundwater	All	All	Ingestion, Dermal Contact, Inhalation of VOCs from use of tap water	None		Groundwater is not considered potable and is not a future source of drinking water. Groundwater would be expected to be supplied by an off-site source.
		Vapors	Vapors from Groundwater to Indoor Air via Vapor Intrusion	Resident	Adult	Inhalation	Quant.	If the site is ever developed for residential use, volatile compounds in groundwater could migrate into indoor air thus making this exposure pathway complete.	
					Child	Inhalation	Quant.	If the site is ever developed for residential use, volatile compounds in groundwater could migrate into indoor air thus making this exposure pathway complete.	
				Commercial/Industrial Worker	Adult	Inhalation	Quant.	If the site is ever developed for industrial use, volatile compounds in groundwater may migrate into indoor air making this pathway complete.	
				Construction Worker	Adult	Inhalation	None	Construction Workers are considered only outdoor receptors.	
				Recreational User	Adult	Inhalation	None	Recreational Users are considered only outdoor receptors.	
					Child	Inhalation	None	Recreational Users are considered only outdoor receptors.	
				VOCs in Outdoor Air	Resident	Adult	Inhalation	Quant.	Volatile compounds in shallow groundwater could volatilize to outdoor air making the pathway potentially complete.
						Child	Inhalation	Quant.	Volatile compounds in shallow groundwater could volatilize to outdoor air making the pathway potentially complete.
		Commercial/Industrial Worker	Adult		Inhalation	Quant.	Volatile compounds in shallow groundwater could volatilize to outdoor air making the pathway potentially complete.		
		Construction Worker	Adult		Inhalation	Quant.	Volatile compounds in shallow groundwater could volatilize to outdoor air making the pathway potentially complete.		
		Recreational User	Adult		Inhalation	Quant.	Volatile compounds in shallow groundwater could volatilize to outdoor air making the pathway potentially complete.		
			Child		Inhalation	Quant.	Volatile compounds in shallow groundwater could volatilize to outdoor air making the pathway potentially complete.		

Notes:

a The most likely future use at the site is a golf course. To provide alternative risk estimates for unrestricted reuse and support risk management decisions, this HHRA conservatively assumed the site may be redeveloped into residential or commercial/industrial property in the future.

**TABLE H-2.1: EPA RAGS PART D TABLE 2, OCCURENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN (CONTINUED)**

Surface Soil (0-2 feet bgs)

Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Scenario Timeframe:	Future
Medium:	Soil
Exposure Medium:	Surface Soil (0-2 ft bgs)

Exposure Point	CAS Number	Chemical	Minimum Detected Concentration (Qualifier)	Maximum Detected Concentration (Qualifier)	Units	Location of Maximum Concentration	Detected	Total	Detection Frequency (Percent)	Number of High Censored Results (1)	Range of Detection Limits	Concentration Used for Screening (2)	Ambient Value (2)	Screening Toxicity Value (2)	Potential ARAR/TBC Source	COPC Flag (Yes/No)	Rationale for Selection or Deletion (2)
----------------	------------	----------	--	--	-------	-----------------------------------	----------	-------	-------------------------------	-------------------------------------	---------------------------	--------------------------------------	-------------------	------------------------------	---------------------------	--------------------	---

Notes:

- (1) The number of high censored (nondetect) results that exceeded the maximum detected datum. These results were excluded from the exposure point concentration calculations provided in the RAGS Table 3.
- (2) Chemicals were not screened against background (ambient) or PRGs. This table provides a comparison of the EPA Region IX PRGs for residential soil (EPA 2004) to the maximum detected concentrations. However, except for essential nutrients, all detected chemicals were included as COPCs.

Definitions:

-	Not available	ft bgs	Feet below ground surface
ARAR/TBC	Applicable or relevant and appropriate requirement/to be considered	J	Estimated Value
CAS	Chemical Abstracts Service	mg/kg	Miligrams per kilogram
COPC	Chemical of Potential Concern	PRG	Preliminary Remediation Goal
EPA	U.S. Environmental Protection Agency	RAGS	Risk Assessment Guidance for Superfund

**TABLE H-2.2: EPA RAGS PART D TABLE 2, OCCURENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN (CONTINUED)**

Surface and Subsurface Soil (0-4 feet bgs)

Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Scenario Timeframe:	Future
Medium:	Soil
Exposure Medium:	Surface and Subsurface Soil (0-4 ft bgs)

Exposure Point	CAS Number	Chemical	Minimum Detected Concentration (Qualifier)	Maximum Detected Concentration (Qualifier)	Units	Location of Maximum Concentration	Detected	Total	Detection Frequency (Percent)	Number of High Censored Results (1)	Range of Detection Limits	Concentration Used for Screening (2)	Ambient Value (2)	Screening Toxicity Value (2)	Potential ARAR/TBC Source	COPC Flag (Yes/No)	Rationale for Selection or Deletion (2)
----------------	------------	----------	--	--	-------	-----------------------------------	----------	-------	-------------------------------	-------------------------------------	---------------------------	--------------------------------------	-------------------	------------------------------	---------------------------	--------------------	---

Notes:

- (1) The number of high censored (nondetect) results that exceeded the maximum detected datum. These results were excluded from the exposure point concentration calculations provided in the RAGS Table 3.
- (2) Chemicals were not screened against background (ambient) or PRGs. This table provides a comparison of the EPA Region IX PRGs for residential soil (EPA 2004) to the maximum detected concentrations. However, except for essential nutrients, all detected chemicals were included as COPCs.

Definitions:

- Not available
- ARAR/TBC Applicable or relevant and appropriate requirement to be considered
- CAS Chemical Abstracts Service
- COPC Chemical of Potential Concern
- EPA U.S. Environmental Protection Agency
- ft bgs Feet below ground surface
- J Estimated Value
- mg/kg Milligrams per kilogram
- PRG Preliminary Remediation Goal
- RAGS Risk Assessment Guidance for Superfund

Notes:

See Appendix G for a detailed description of the statistical methods used.

BCa Bias-corrected accelerated

DF Detection frequency

EPC Exposure point concentration

J Estimated value

KM Kaplan-Meier product limit estimator

N/A Not applicable, no result reported because the sample size was less than four.

MVUE Minimum variance unbiased estimate

mg/kg Milligrams per kilogram

UCL One-sided upper confidence limit of the mean. Following EPA (2002, 2004, 2006), this can be either a 95, 97.5, or 99 percent UCL.

a Tested for detected data only using the Shapiro-Wilk W test (normal and lognormal distributions) and the Cramer von Mises W\* test (gamma distributions).

A 5 percent level of significance was used in all tests. Distribution tests were only conducted for samples with at least 8 detected measurements.

All other chemical distributions were treated as nonparametric in calculations of the mean, UCL, and EPC.

Distribution Codes: G= gamma, L= lognormal, N= normal, NP= nonparametric

b For detected data only, methods followed EPA (2002, 2004). For chemicals with at least one censored (nondetect) measurement, methods followed recommendations in EPA (2006). The EPC is the lesser of the UCL and the maximum detected concentration.

Method (Statistic) Codes are defined as follows:

(1) Maximum detected concentration

(2) 95 percent UCL calculated using Student's t distribution

(3) 95 percent UCL calculated using Land's H statistic

(4), (5), (6) 95, 97.5, or 99 percent UCL, respectively, calculated using the nonparametric Chebyshev method

(7), (8), (9) 95, 97.5, or 99 percent UCL, respectively, calculated using the MVUE Chebyshev method

(10) 95 percent UCL calculated using the approximate gamma method

(11) 95 percent UCL calculated using the adjusted gamma method

(12) 95 percent UCL calculated using the KM mean and Student's t cutoff for the UCL

(13), (14), (15) 95, 97.5, or 99 percent UCL, respectively, calculated using the KM mean and the nonparametric Chebyshev method to estimate the UCL

(16) 95 percent UCL calculated using the KM mean and a percentile bootstrap to estimate the UCL

(17) 95 percent UCL calculated using the KM mean and a BCa bootstrap to estimate the UCL

Notes:

See Appendix G for a detailed description of the statistical methods used.

BCa Bias-corrected accelerated

DF Detection frequency

EPC Exposure point concentration

J Estimated value

KM Kaplan-Meier product limit estimator

N/A Not applicable, no result reported because the sample size was less than four.

MVUE Minimum variance unbiased estimate

mg/kg Milligrams per kilogram

UCL One-sided upper confidence limit of the mean. Following EPA (2002, 2004, 2006), this can be either a 95, 97.5, or 99 percent UCL.

a Tested for detected data only using the Shapiro-Wilk W test (normal and lognormal distributions) and the Cramer von Mises  $W^2$  test (gamma distributions).

A 5 percent level of significance was used in all tests. Distribution tests were only conducted for samples with at least 8 detected measurements.

All other chemical distributions were treated as nonparametric in calculations of the mean, UCL, and EPC.

Distribution Codes: G= gamma, L= lognormal, N= normal, NP= nonparametric

b For detected data only, methods followed EPA (2002, 2004). For chemicals with at least one censored (nondetect) measurement,

methods followed recommendations in EPA (2006). The EPC is the lesser of the UCL and the maximum detected concentration.

Method (Statistic) Codes are defined as follows:

(1) Maximum detected concentration

(2) 95 percent UCL calculated using Student's *t* distribution

(3) 95 percent UCL calculated using Land's H statistic

(4), (5), (6) 95, 97.5, or 99 percent UCL, respectively, calculated using the nonparametric Chebyshev method

(7), (8), (9) 95, 97.5, or 99 percent UCL, respectively, calculated using the MVUE Chebyshev method

(10) 95 percent UCL calculated using the approximate gamma method

(11) 95 percent UCL calculated using the adjusted gamma method

**TABLE H-3.3: EPA RAGS PART D TABLE 3, EXPOSURE POINT CONCENTRATION SUMMARY (CONTINUED)**

**Groundwater**

Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Notes:

See Appendix G for a detailed description of the statistical methods used.

BCa	Bias-corrected accelerated
DF	Detection frequency
EPC	Exposure point concentration
J	Estimated value
KM	Kaplan-Meier product limit estimator
N/A	Not applicable, no result reported because the sample size was less than four.
MVUE	Minimum variance unbiased estimate
mg/kg	Milligrams per kilogram
UCL	One-sided upper confidence limit of the mean. Following EPA (2002, 2004, 2006), this can be either a 95, 97.5, or 99 percent UCL.
a	Tested for detected data only using the Shapiro-Wilk W test (normal and lognormal distributions) and the Cramer von Mises W <sup>2</sup> test (gamma distributions). A 5 percent level of significance was used in all tests. Distribution tests were only conducted for samples with at least 8 detected measurements. All other chemical distributions were treated as nonparametric in calculations of the mean, UCL, and EPC. <u>Distribution Codes:</u> G= gamma, L= lognormal, N= normal, NP= nonparametric
b	For detected data only, methods followed EPA (2002, 2004). For chemicals with at least one censored (nondetect) measurement, methods followed recommendations in EPA (2006). The EPC is the lesser of the UCL and the maximum detected concentration. <u>Method (Statistic) Codes are defined as follows:</u>
(1)	Maximum detected concentration
(2)	95 percent UCL calculated using Student's t distribution
(3)	95 percent UCL calculated using Land's H statistic
(4), (5), (6)	95, 97.5, or 99 percent UCL, respectively, calculated using the nonparametric Chebyshev method
(7), (8), (9)	95, 97.5, or 99 percent UCL, respectively, calculated using the MVUE Chebyshev method
(10)	95 percent UCL calculated using the approximate gamma method
(11)	95 percent UCL calculated using the adjusted gamma method
(12)	95 percent UCL calculated using the KM mean and Student's t cutoff for the UCL
(13), (14), (15)	95, 97.5, or 99 percent UCL, respectively, calculated using the KM mean and the nonparametric Chebyshev method to estimate the UCL
(16)	95 percent UCL calculated using the KM mean and a percentile bootstrap to estimate the UCL
(17)	95 percent UCL calculated using the KM mean and a BCa bootstrap to estimate the UCL

**TABLE H-3.4: EXPOSURE POINT CONCENTRATION SUMMARY (CONTINUED)**  
**Ambient Air Concentrations via Volatilization in Surface Soil (0 to 2 feet bgs)**

$$VF = Q/C \times (3.14 \times D_A \times T)^{1/2} \times 10^{-4} \text{ (m}^2\text{/cm}^2\text{)} / (2 \times \rho_b \times D_A)$$

$$D_A = \frac{((\theta_a^{10/3} \times D_i \times H') + (\theta_w^{10/3} \times D_w)) / n^2}{((\rho_b \times K_d) + \theta_w + (\theta_a \times H'))}$$

$$C_A = C_S / VF$$

Parameter	Definition	Value	Source
VF	Volatilization factor (m <sup>2</sup> /kg)	chemical-specific	Calculated from above equation (EPA 1996, 2004)
D <sub>A</sub>	Apparent diffusivity (cm <sup>2</sup> /s)	chemical-specific	Calculated from above equation (EPA 1996, 2004)
C <sub>A</sub>	Concentration in ambient air (mg/m <sup>3</sup> )	chemical-specific	Calculated from above equation
C <sub>S</sub>	Concentration in soil (mg/kg)	chemical-specific	See RAGS Table H3.1
θ <sub>a</sub>	Air filled soil porosity (unitless)	0.321	Calculated based on soil type using Johnson and Ettinger Model
θ <sub>w</sub>	Water filled soil porosity (unitless)	0.054	Calculated based on soil type using Johnson and Ettinger Model
T	Exposure interval (s)	9.50E+08	Default value (EPA 1996, 2004)
n	Total soil porosity = 1 - (pb/ps)	0.37	
Pb	Dry soil bulk density (g/cm <sup>3</sup> )	1.66	Calculated based on soil type using Johnson and Ettinger Model
Ps	Soil particle density (g/cm <sup>3</sup> )	2.65	Default value (EPA 1996, 2004)
foc	Fraction organic carbon in soil (g/g)	0.002	Default value used in Johnson and Ettinger Model
Q/C	Inverse of the mean concentration at the center of a 5-acre square source (g/m <sup>2</sup> -s per kg/m <sup>3</sup> )	60.03	Exhibit 11 (EPA 1996)
D <sub>i</sub>	Diffusivity in air (cm <sup>2</sup> /s)	chemical-specific	VLOOKUP table from Johnson and Ettinger Model
H'	Dimensionless Henry's Law Constant	chemical-specific	VLOOKUP table from Johnson and Ettinger Model
D <sub>w</sub>	Diffusivity in water (cm <sup>2</sup> /s)	chemical-specific	VLOOKUP table from Johnson and Ettinger Model
K <sub>oc</sub>	Soil organic carbon partition coefficient (cm <sup>3</sup> /g)	chemical-specific	VLOOKUP table from Johnson and Ettinger Model
K <sub>d</sub>	Soil-water partition coefficient (cm <sup>3</sup> /g) = K <sub>oc</sub> × f <sub>oc</sub>	chemical-specific	VLOOKUP table from Johnson and Ettinger Model

(a) The HHRA used surrogates for chemicals lacking data for these parameters values. Surrogates used include 1,2,4-Trichlorobenzene for 1,2,3-Trichlorobenzene, Acenaphthene for Acenaphthylene, Anthracene, and Phenanthrene; Cumene for p-isopropyltoluene; gamma-HCH for Delta-BHC; Endosulfan for Endosulfan I & II and for Endosulfan sulfate; benzo(b)fluoranthene for fluoranthene; chlordane for Technical chlordane, alpha and gamma-chlordane; alpha-HCH for alpha-BHC; gamma-HCH for gamma-BHC.

**TABLE H-3.5: EXPOSURE POINT CONCENTRATION SUMMARY (CONTINUED)**  
**Ambient Air Concentrations via Volatilization in Surface and Subsurface Soil (0 to 4 feet bgs)**

$$VF = Q/C \times (3.14 \times D_A \times T)^{1/2} \times 10^{-4} (m^2/cm^2)/(2 \times \rho_b \times D_A)$$

$$D_A = (((\theta_a^{10/3} \times D_i \times H') + (\theta_w^{10/3} \times D_w)) / n^2) / ((\rho_b \times K_d) + \theta_w + (\theta_a \times H'))$$

$$C_A = C_S / VF$$

Parameter	Definition	Value	Source
VF	Volatilization factor (m <sup>3</sup> /kg)	chemical-specific	Calculated from above equation (EPA 1996, 2004)
D <sub>A</sub>	Apparent diffusivity (cm <sup>2</sup> /s)	chemical-specific	Calculated from above equation (EPA 1996, 2004)
C <sub>A</sub>	Concentration in ambient air (mg/m <sup>3</sup> )	chemical-specific	Calculated from above equation
C <sub>S</sub>	Concentration in soil (mg/kg)	chemical-specific	See RAGS Table H3.1
θ <sub>a</sub>	Air filled soil porosity (unitless)	0.321	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
θ <sub>w</sub>	Water filled soil porosity (unitless)	0.054	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
T	Exposure interval (s)	9.50E+08	Default value (EPA 1996, 2004)
n	Total soil porosity = 1 - (pb/ps)	0.37	
P <sub>b</sub>	Dry soil bulk density (g/cm <sup>3</sup> )	1.66	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
P <sub>s</sub>	Soil particle density (g/cm <sup>3</sup> )	2.65	Default value (EPA 1996, 2004)
foc	Fraction organic carbon in soil (g/g)	0.002	Default value used in Johnson and Ettinger Model (DTSC 2003)
Q/C	Inverse of the mean concentration at the center of a 5-acre square source (g/m <sup>2</sup> -s per kg/m <sup>3</sup> )	60.03	Exhibit 11 (EPA 1996)
D <sub>i</sub>	Diffusivity in air (cm <sup>2</sup> /s)	chemical-specific	VLOOKUP table from Johnson and Ettinger Model (DTSC 2003)
H'	Dimensionless Henry's Law Constant	chemical-specific	VLOOKUP table from Johnson and Ettinger Model (DTSC 2003)
D <sub>w</sub>	Diffusivity in water (cm <sup>2</sup> /s)	chemical-specific	VLOOKUP table from Johnson and Ettinger Model (DTSC 2003)
K <sub>oc</sub>	Soil organic carbon partition coefficient (cm <sup>3</sup> /g)	chemical-specific	VLOOKUP table from Johnson and Ettinger Model (DTSC 2003)
K <sub>d</sub>	Soil-water partition coefficient (cm <sup>3</sup> /g) = K <sub>oc</sub> × f <sub>oc</sub>	chemical-specific	

(a) The HHRA used surrogates for some chemicals for these parameters. Surrogates used include 1,2,4-Trichlorobenzene for 1,2,3-Trichlorobenzene, Acenaphthene for Acenaphthylene, Anthracene, and Phenanthrene; Cumene for p-isopropyltoluene; gamma-HCH for Delta-BHC; Endosulfan for Endosulfan I & II and for Endosulfan sulfate; benzo(b)fluoranthene for fluoranthene; chlordane for Technical chlordane, alpha and gamma-chlordane; alpha-HCH for alpha-BHC; gamma-HCH for gamma-BHC.

**TABLE H-3.6: EXPOSURE POINT CONCENTRATION SUMMARY (CONTINUED)**  
**Ambient Air Concentrations via Volatilization in Groundwater**

$$VF = H / (1 + ((U_{air} \times \delta \times L_{GW}) / (W \times D_{VGS})) \times 1000 \text{ L/m}^3$$

$$D_{VGS} = (h_{cap} + hv) \times ((h_{cap} / D_{cap}) + (hv / D_s))^{-1}$$

$$D_{cap} = (D_i \times (\theta^{3.33}_{acap} / (\theta^2_T))) + ((D_W \times 1/H \times ((\theta^{3.33}_{wcap}) / \theta^2_T)))$$

$$D_s = (D_i \times (\theta^{3.33}_{as} / \theta^2_T)) + (D_W \times 1/H \times (\theta^{3.33}_{ws} / \theta^2_T))$$

$$C_A = C_W \times VF$$

Parameter	Definition	Value	Source
VF	Volatilization factor (mg/m <sup>3</sup> / mg/L)	chemical-specific	Calculated from above equation (ASTM 1995)
D <sub>VGS</sub>	Effective diffusion coefficient between groundwater and soil surface (cm <sup>2</sup> /s)	chemical-specific	Calculated from above equation (ASTM 1995)
D <sub>cap</sub>	Effective diffusion coefficient through capillary fringe (cm <sup>2</sup> /s)	chemical-specific	Calculated from above equation (ASTM 1995)
D <sub>s</sub>	Effective diffusivity in vadose zone (cm <sup>2</sup> /s)	chemical-specific	Calculated from above equation (ASTM 1995)
C <sub>A</sub>	Concentration in ambient air (mg/m <sup>3</sup> )	chemical-specific	Calculated from above equation
C <sub>W</sub>	Concentration in groundwater (mg/kg)	chemical-specific	See RAGS Table H3.3
θ <sub>cap</sub>	Capillary fringe air filled porosity (unitless)	0.122	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
θ <sub>wcap</sub>	Capillary fringe water filled porosity (unitless)	0.253	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
θ <sub>t</sub>	Soil total porosity	0.375	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
θ <sub>as</sub>	Soil air filled soil porosity (unitless)	0.321	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
θ <sub>ws</sub>	Soil water filled soil porosity (unitless)	0.054	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
U <sub>air</sub>	Wind speed above ground surface in ambient mixing zone (cm/s)	225	ASTM default (ASTM 1995)
δ	Height of air mixing zone (cm)	200	ASTM default (ASTM 1995)
L <sub>GW</sub>	Depth to groundwater (cm)	121.9	Site-specific
W	Width of source area parallel to the wind (cm)	12,192	Site-specific
h <sub>cap</sub>	Thickness of capillary fringe (cm)	17.05	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
h <sub>v</sub>	Thickness of vadose zone (cm)	104.85	Calculated based on soil type using Johnson and Ettinger Model (DTSC 2003)
D <sub>i</sub>	Diffusivity in air (cm <sup>2</sup> /s)	chemical-specific	VLOOLUP table from Johnson and Ettinger Model (DTSC 2003)
H	Dimensionless Henry's Law Constant	chemical-specific	VLOOLUP table from Johnson and Ettinger Model (DTSC 2003)
D <sub>w</sub>	Diffusivity in water (cm <sup>2</sup> /s)	chemical-specific	VLOOLUP table from Johnson and Ettinger Model (DTSC 2003)

(a) The HHRA used surrogates for some chemicals for these parameters. Surrogates used include 1,2,4-Trichlorobenzene for 1,2,3-Trichlorobenzene, Acenaphthene for Acenaphthylene, Anthracene, and Phenanthrene; Cumene for p-isopropyltoluene; gamma-HCH for Delta-BHC; Endosulfan for Endosulfan I & II and for Endosulfan sulfate; benzo(b)fluoranthene for fluoranthene; chlordane for Technical chlordane, alpha and gamma-chlordane; alpha-HCH for alpha-BHC; gamma-HCH for gamma-BHC.

				AT-C	Averaging Time - Cancer	25,550	days	EPA 1989	
AT-NC	Averaging Time - Noncancer	2,190	days	EPA 1989					

Notes:

- (1) See Section H5.5 for discussion of the intake assumptions.
- (2) While children's inhalation rates can be estimated, the toxicity factors applied in a risk assessment are based on chronic risks and not adjusted for a child's unique physiology.
- (3) These exposure times for inhalation are shown to represent the total daily inhalation rate on an hourly basis; however, because some outdoor activity is being assumed based on the inclusion of soil pathways and outdoor air inhalation, this will result in a conservative overestimate of risk, unless soil (vapor and particulate) and groundwater (indoor air) pathways are characterized separately.

Notes:

- (1) See Section H5.5 for discussion of the intake assumptions.
- (2) While children's inhalation rates can be estimated, the toxicity factors applied in a risk assessment are based on chronic risks and not adjusted for a child's unique physiology.
- (3) These exposure times for inhalation are shown to represent the total daily inhalation rate on an hourly basis; however, because some outdoor activity is being assumed based on the inclusion of soil pathways and outdoor air inhalation, this will result in a conservative overestimate of risk, unless soil (vapor and particulate) and groundwater (indoor air) pathways are characterized separately.

Notes:

- a Assumed most conservative gastrointestinal absorption of 100%. Value obtained from EPA (2004c).
- b Per EPA's Dermal Guidance document (EPA 2004c), organic and inorganic COPCs without ABS<sup>GI</sup> values listed in Exhibit 4-1 of EPA (2004c) were assigned an ABSGI value of 100%. Per EPA's Dermal Guidance document (EPA 2004c), arsenic had a ABS<sup>GI</sup> value greater than 50% in Exhibit 4-1 of EPA (2004c) and therefore was assigned an ABS<sup>GI</sup> value of 100%. Note that when a range of ABS<sup>GI</sup> values was presented in Exhibit 4-1 of EPA (2004c), the lowest number in the range was used, which was the most conservative approach.
- c 1,2,4-trichlorobenzene used as a surrogate for toxicity information.
- d 2-Butanone used as a surrogate for toxicity information.
- e 4,4'-DDT used as surrogate for toxicity information.
- f Nitrobenzene used as a surrogate for toxicity information.
- g Acenaphthene used as a surrogate for toxicity information.
- h Chlordane used as a surrogate for toxicity information.
- i Aroclor 1254 used as a surrogate for toxicity information.
- j Pyrene used as a surrogate for toxicity information.
- k Chromium III used as a surrogate for toxicity information.
- l Beta-BHC used as a surrogate for toxicity information.
- m Endosulfan used as a surrogate for toxicity information.
- n Endrin used as a surrogate for toxicity information.
- o The toxicity value for total xylenes was used as a surrogate for m,p-xylenes
- p As recommended in IRIS (EPA, 2006) and described in the EPA Region 9 PRG technical memorandum (2004a), the RID for manganese was modified to account for dietary contribution of manganese from the normal diet.
- q Mercuric chlordane used as a surrogate for toxicity information.
- r Nickel (soluble salts) used as a surrogate for toxicity information.
- s Anthracene used as a surrogate for toxicity information.
- t Isopropylbenzene used as a surrogate for toxicity information.
- u The toxicity value for thallium sulfate was adjusted as described in the EPA Region 9 PRG Table technical memorandum (2004a). Based on the molecular weight of thallium sulfate, an adjustment was made to obtain an oral RID for plain thallium.

Notes:

- a Assumed most conservative gastrointestinal absorption of 100%. Value obtained from EPA (2004c).
- b Per EPA's Dermal Guidance document (EPA 2004c), organic and inorganic COPCs without ABS<sup>GI</sup> values listed in Exhibit 4-1 of EPA (2004c) were assigned an ABS<sup>GI</sup> value of 100%. Per EPA's Dermal Guidance document (EPA 2004c), arsenic had a ABS<sup>GI</sup> value greater than 50% in Exhibit 4-1 of EPA (2004c) and therefore was assigned an ABS<sup>GI</sup> value of 100%. Note that when a range of ABS<sup>GI</sup> values was presented in Exhibit 4-1 of EPA (2004c), the lowest number in the range was used, which was the most conservative approach.
- c Chlordane used as surrogate for toxicity information.
- d The upper-bound oral cancer slope factor for polychlorinated biphenyls (high risk and persistence) was used.
- e The high range oral slope factor for benzene in IRIS was used.
- f As cited in IRIS, "The Proposed Guidelines for Carcinogenic Risk Assessment (U.S. EPA, 1996) state that when the mode-of-action analysis based on available data indicates that 'the carcinogenic response is secondary to another toxicity that has a threshold, the margin-of-exposure analysis performed for toxicity is the same as is done for a noncancer endpoint, and an RfD for that toxicity may be considered in the cancer assessment.' For chloroform, available evidence indicates that chloroform-induced carcinogenicity is secondary to cytotoxicity and regenerative hyperplasia; hence, EPA relies on a nonlinear dose-response approach and the use of a margin-of-exposure analysis for cancer risk. EPA has also chosen not to rely on a mathematical model to estimate a point of departure for cancer risk estimate, because the mode of action indicates that cytotoxicity is the critical effect and the reference dose value is considered protective for this effect."
- g The toxicity value for beta-BHC was used as a surrogate.

**Method 1 Values (EPA Sources)**

Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Chemical of Potential Concern	Unit Risk		Inhalation Cancer Slope Factor		Weight of Evidence/ Cancer Guideline Description	Unit Risk : Inhalation Cancer Slope Factor	
	Value	Units	Value	Units		Source(s)	Date(s)

Notes:

- a Chlordane used as a surrogate for toxicity information.
- a The upper-bound oral cancer slope factor for high risk and persistent polychlorinated biphenyls was used.
- c The high range oral slope factor for benzene in IRIS was used.
- d Toxicity information for Chromium III.
- e The toxicity value for beta-BHC was used as a surrogate.
- f No unit risk or inhalation cancer slope factor was selected for naphthalene for Method 1. An inhalation unit risk estimate for naphthalene has not been derived by EPA because of the weakness of the evidence that naphthalene may be carcinogenic.

Definitions:

- Not available; not applicable
- µg/m<sup>3</sup> Micrograms per cubic meter
- BHC Hexachlorocyclohexane
- DDD Dichlorodiphenyldichloroethane
- DDE Dichlorodiphenyldichloroethane
- DDT Dichlorodiphenyltrichloroethane
- EPA U.S. Environmental Protection Agency
- HHRA Human Health Risk Assessment
- IRIS EPA Integrated Risk Information System (EPA 2006)
- mg/kg-day Milligram per kilogram per day
- PPRTV Provisional Peer Reviewed Toxicity Value for Superfund (EPA 2004b)
- R9-N National Center for Environmental Assessment (NCEA) value as shown in EPA Region 9 PRG Table (EPA 2004a).
- R9-R Source of toxicity value listed as "route extrapolation" in the EPA Region 9 PRG Table (EPA 2004a)
- RAGS Risk Assessment Guidance for Superfund

Zinc	Chronic	3.0E-01	mg/kg-day	100%	3.0E-01	mg/kg-day	Blood	3	IRIS	4/5/2007

Notes:

- a Assumed most conservative gastrointestinal absorption of 100%. Value obtained from EPA (2004c).
- b Per EPA's Dermal Guidance document (EPA 2004c), organic and inorganic COPCs without ABS<sup>GI</sup> values listed in Exhibit 4-1 of EPA (2004c) were assigned an ABS<sup>GI</sup> value of 100%. Per EPA's Dermal Guidance document (EPA 2004c), arsenic had a ABS<sup>GI</sup> value greater than 50% in Exhibit 4-1 of EPA (2004c) and therefore was assigned an ABS<sup>GI</sup> value of 100%. Note that when a range of ABS<sup>GI</sup> values was presented in Exhibit 4-1 of EPA (2004c), the lowest number in the range was used, which was the most conservative approach.
- c 1,2,4-Trichlorobenzene used as a surrogate for toxicity information.
- d 2-Butanone used as a surrogate for toxicity information.
- e 4,4'-DÖT used as surrogate for toxicity information.
- f Nitrobenzene used as a surrogate for toxicity information.
- g Acenaphthene used as a surrogate for toxicity information.
- h Chlordane used as a surrogate for toxicity information.
- i Aroclor 1254 used as a surrogate for toxicity information.
- j Pyrene used as a surrogate for toxicity information.
- k Chromium III used as a surrogate for toxicity information.
- l Beta-BHC used as a surrogate for toxicity information.
- m Endosulfan used as a surrogate for toxicity information.
- n Endrin used as a surrogate for toxicity information.
- o The toxicity value for total xylenes was used as a surrogate for m,p-xylenes
- p As recommended in IRIS (EPA, 2006) and described in the EPA Region 9 PRG technical memorandum (2004a), the RfD for manganese was modified to account for dietary contribution of manganese from the normal diet.
- q Mercuric chlordane used as a surrogate for toxicity information.
- r Nickel (soluble salts) used as a surrogate for toxicity information.
- s Anthracene used as a surrogate for toxicity information.
- t Isopropylbenzene used as a surrogate for toxicity information.
- u The toxicity value for thallium sulfate was adjusted as described in the EPA Region 9 PRG Table technical memorandum (2004a). Based on the molecular weight of thallium sulfate, an adjustment was made to obtain an oral RfD for plain thallium.

Notes:

- a 1,2,4-trichlorobenzene was used as a surrogate for toxicity information.
- b 2-butanone used as a surrogate for toxicity information.
- c 4,4-DDT used as a surrogate for toxicity information.
- d Nitrobenzene used as a surrogate for toxicity information.
- e Acenaphthene used as a surrogate for toxicity information.
- f Chlordane used as a surrogate for toxicity information.
- g Aroclor 1254 used as a surrogate for toxicity information.
- h Pyrene used as a surrogate for toxicity information.
- i Beta-BHC used as a surrogate for toxicity information.
- j Endosulfan used as a surrogate for toxicity information.
- k Endrin used as a surrogate for toxicity information.
- l The toxicity value for total xylenes was used as a surrogate for m,p-xylenes
- m Elemental mercury used as a surrogate for toxicity information.
- n Anthracene used as a surrogate for toxicity information.
- o Isopropylbenzene used as a surrogate for toxicity information.
- p Thallium chloride used as a surrogate for toxicity information.

Zinc	--	--	--	--	--	D	IRIS	4/5/2007

Notes:

- a Assumed most conservative gastrointestinal absorption of 100%. Value obtained from EPA (2004c).
- b Per EPA's Dermal Guidance document (EPA 2004c), organic and inorganic COPCs without ABS<sup>GI</sup> values listed in Exhibit 4-1 of EPA (2004c) were assigned an ABS<sup>GI</sup> value of 100%. Per EPA's Dermal Guidance document (EPA 2004c), arsenic had a ABS<sup>GI</sup> value greater than 50% in Exhibit 4-1 of EPA (2004c) and therefore was assigned an ABS<sup>GI</sup> value of 100%. Note that when a range of ABS<sup>GI</sup> values was presented in Exhibit 4-1 of EPA (2004c), the lowest number in the range was used, which was the most conservative approach.
- c Chlordane used as surrogate for toxicity information.
- d The upper-bound oral cancer slope factor for polychlorinated biphenyls (high risk and persistence) was used.
- e The toxicity value for beta-BHC was used as a surrogate.

Method 2 Values (DTSC-Preferred Sources)**

Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Chemical of Potential Concern	Unit Risk		Inhalation Cancer Slope Factor		Weight of Evidence/ Cancer Guideline Description	Unit Risk : Inhalation Cancer Slope Factor	
	Value	Units	Value	Units		Source(s)	Date(s)

Notes:

- a Chlordane used as a surrogate for toxicity information.
- b The upper-bound oral cancer slope factor for high risk and persistent polychlorinated biphenyls was used.
- c Toxicity information for Chromium III.
- d The toxicity value for beta-BHC was used as a surrogate.

Definitions:

- Not available; not applicable
- µg/m<sup>3</sup> Micrograms per cubic meter
- BHC Hexachlorocyclohexane
- DDD Dichlorodiphenyldichloroethane
- DDE Dichlorodiphenyldichloroethene
- DDT Dichlorodiphenyltrichloroethane
- EPA U.S. Environmental Protection Agency
- HHRA Human Health Risk Assessment
- IRIS EPA Integrated Risk Information System (EPA 2007)
- mg/kg-day Milligram per kilogram per day
- PPRTV Provisional Peer Reviewed Toxicity Value for Superfund (EPA 2004b)
- R9-N National Center for Environmental Assessment (NCEA) value as shown in EPA Region 9 PRG Table (EPA 2004a).
- R9-R Source of toxicity value listed as "route extrapolation" in the EPA Region 9 PRG Table (EPA 2004a)
- RAGS Risk Assessment Guidance for Superfund

TABLE H-7.3

EPA RAGS PART D TABLE 7a-b, CALCULATION OF RME CHEMICAL CANCER RISKS AND NONCANCER HAZARDS USING TOXICITY DATA FROM EPA SOURCES (METHOD 1)  
 CONSTRUCTION WORKER, SURFACE SOIL (0 TO 2 FEET BGS) (continued)  
 Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Scenario Timeframe:	Future
Receptor Population:	Construction Worker
Receptor Age:	Adult

Medium	Exposure Medium	Exposure Point	Exposure Route	Chemical of Potential Concern	EPC		Cancer Risk Calculations					Non-Cancer Hazard Calculations				
					Value	Units	Intake/Exposure Concentration		CSF/Unit Risk		Cancer Risk	Intake/Exposure Concentration		RID/RIC		Hazard Quotient
							Value	Units	Value	Units		Value	Units	Value	Units	
Soil (0-2 ft bgs) (continued)	Soil (continued)	Site Soil (continued)	Dermal (continued)	4-Nitrophenol	4.20E-01	mg/kg	2.68E-08	mg/kg-day	--	--	--	1.87E-06	mg/kg-day	5.00E-04	mg/kg-day	3.75E-03

TABLE H-7.5

EPA RAGS PART D TABLE 7a-b, CALCULATION OF RME CHEMICAL CANCER RISKS AND NONCANCER HAZARDS USING TOXICITY DATA FROM EPA SOURCES (METHOD 1)  
 ADULT RESIDENT, SURFACE SOIL (0 TO 2 FEET BGS) (continued)  
 Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Scenario Timeframe: Future  
 Receptor Population: Resident  
 Receptor Age: Adult

Medium	Exposure Medium	Exposure Point	Exposure Route	Chemical of Potential Concern	EPC		Cancer Risk Calculations					Non-Cancer Hazard Calculations								
					Value	Units	Intake/Exposure Concentration		CSF/Unit Risk		Cancer Risk	Intake/Exposure Concentration		RID/RIC		Hazard Quotient				
							Value	Units	Value	Units		Value	Units	Value	Units					
Soil (0-2 ft bgs) (continued)	Soil (continued)	Site Soil (continued)	Dermal (continued)	Manganese	3.31E+02	mg/kg	6.20E-07	mg/kg-day	--	--	--	--	1.81E-06	mg/kg-day	2.40E-02	mg/kg-day	7.54E-05

TABLE H-7.6

EPA RAGS PART D TABLE 7a-b, CALCULATION OF RME CHEMICAL CANCER RISKS AND NONCANCER HAZARDS USING TOXICITY DATA FROM EPA SOURCES (METHOD 1)  
 ADULT RESIDENT, SURFACE AND SUBSURFACE SOIL (0 TO 4 FEET BGS) (continued)  
 Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Scenario Timeframe: Future  
 Receptor Population: Resident  
 Receptor Age: Adult

Medium	Exposure Medium	Exposure Point	Exposure Route	Chemical of Potential Concern	EPC		Cancer Risk Calculations					Non-Cancer Hazard Calculations				
					Value	Units	Intake/Exposure Concentration		CSF/Unit Risk		Cancer Risk	Intake/Exposure Concentration		RfD/RfC		Hazard Quotient
							Value	Units	Value	Units		Value	Units	Value	Units	
Soil (0-4 ft bgs) (continued)	Air (continued)	Outdoor Air (continued)	Inhalation (Particulates) (continued)	Thallium	3.66E-10	mg/m <sup>3</sup>	3.42E-11	mg/kg-day	--	--	--	9.98E-11	mg/kg-day	--	--	--

TABLE H-7.8

EPA RAGS PART D TABLE 7a-b, CALCULATION OF RME CHEMICAL CANCER RISKS AND NONCANCER HAZARDS USING TOXICITY DATA FROM EPA SOURCES (METHOD 1)  
 CHILD RESIDENT, SURFACE AND SUBSURFACE SOIL (0 TO 4 FEET BGS) (continued)  
 Appendix H, HHRA for Site 34 Alameda Point, Alameda, California

Scenario Timeframe:	Future
Receptor Population:	Resident
Receptor Age:	Child

Medium	Exposure Medium	Exposure Point	Exposure Route	Chemical of Potential Concern	EPC		Cancer Risk Calculations					Non-Cancer Hazard Calculations						
					Value	Units	Intake/Exposure Concentration		CSF/Unit Risk		Cancer Risk	Intake/Exposure Concentration		RfD/RfC		Hazard Quotient		
							Value	Units	Value	Units		Value	Units	Value	Units			
Soil (0-4 ft bgs) (continued)	Soil (continued)	Site Soil (continued)	Dermal (continued)	Lead	2.39E+03	mg/kg	7.59E-06	mg/kg-day	--	--	--	--	8.86E-05	mg/kg-day	--	--	--	
				Manganese	3.04E+02	mg/kg	9.67E-07	mg/kg-day	--	--	--	--	1.13E-05	mg/kg-day	2.40E-02	mg/kg-day	4.70E-04	--
