# APPENDIX C
# AVERAGE LINEAR VELOCITY CALCULATIONS

# APPENDIX C
# BASIS FOR HYDROGEOLOGICAL CALCULATIONS

Groundwater and the associated VOC plume migration rates are estimated using hydrogeological data collected from Northrop Grumman and NWIRP wells in 2016 and values of aquifer hydraulic conductivities from recent field studies. Plume migration rates may vary from the groundwater flow rates due to non-uniform flow pathways, dilution, area-wide pumping by supply wells, and targeted VOC mass removal from groundwater by remedial wells.

The 2016 groundwater data included measured groundwater depths (i.e., levels) at area-wide monitoring wells. The levels were converted to elevation and plotted on regional maps to develop groundwater contour maps. Using these data, groundwater elevation contour maps were developed for the four depth intervals: less than 300 feet bgs (Figure 3-9); 300 to 500 feet bgs (Figure 3-10); 500 to 700 feet bgs (Figure 3-11); and greater than 700 feet bgs (Figure 3-12). With this level of detail, groundwater flow velocities could be estimated for various locations in the study area and different vertical hydrogeologic zones.

The migration of VOCs is dependent on several factors. On a microscopic scale, groundwater (and groundwater contaminants) moves through open pore spaces in saturated aquifer sediments comprised of gravel, sand, silt, and clay in response to elevation and/or pressure-head differences (i.e., hydraulic gradients) between two locations. Over larger areas, the “average linear velocity” that can be computed, represents the average path of groundwater in the subsurface. The average linear velocity provides an estimate of how long it would take groundwater (and a non-reactive chemical) to move in an aquifer. Average linear velocity is computed using hydraulic conductivity, hydraulic gradient (determined from a groundwater contour map), and effective porosity (i.e., specific yield).

Hydraulic conductivities and effective porosities selected for the average linear groundwater flow velocity analyses for each depth interval are as follows:

- 0 to 300 feet bgs: 50 feet per day and a porosity of 25 percent
- 300 to 500 feet bgs: 78 feet per day and a porosity of 25 percent
- 500 to 700 feet bgs: 87 feet per day and a porosity of 25 percent
- Greater than 700 feet bgs: 120 feet per day and a porosity of 25 percent

Hydraulic conductivities for the three lower zones (300 to 500 feet bgs; 500 to 700 feet bgs; greater than 700 feet bgs) were obtained from recent site aquifer pumping tests conducted at Bethpage Water District Well 6-2 (Resolution, 2016). Data from other similar tests conducted at Bethpage Water District Well 6-2 (Tetra Tech, 2014 and Resolution, 2016) and GM38 Area Hotspot (OU2) (Tetra Tech, 2010) were also considered. Of the three studies, the 2016 Resolution evaluation was the most comprehensive aquifer pumping test for the area in duration (6 weeks versus 3 days) and the number of wells monitored. The testing also included two periods of pumping that provided comparable results for each analysis.

Hydraulic conductivity values from these pumping tests did not evaluate the shallow aquifer zone (0 to 300 feet bgs). Therefore, the shallow aquifer zone hydraulic conductivity (50 feet per day) is based on the final calibrated conductivity for the unconfined Magothy aquifer from the groundwater flow model developed by the U.S. Geological Survey (USGS) for the GM38 Hot Spot (OU2) capture zone analysis (Misut, 2014). The model-based glacial aquifer zone (upper portion of this zone) hydraulic conductivity of 200 feet per day was not incorporated into the 0 to 300 feet bgs zone because the VOCs are predominantly in the Magothy aquifer, particularly in the downgradient plume edge located south of Hempstead Turnpike.

A porosity of 25 percent is used for the current analysis and represents a typical porosity for sand, sand mixtures, and gravels (Spitz and Moreno, 1996); is the mid-range for porosities cited in literature for Long Island outwash deposits (ARCADIS, 2003); and has been used in prior site groundwater modeling efforts (Misut, 2014; ARCADIS, 2010, 2003).

Hydraulic gradients are presented in in Figures 3-9 through 3-12. These groundwater flow paths cover the entire study area and would incorporate effects from pumping wells active at the time of the measurements (May 2016). The month of May represents a moderate pumping period for the local water districts, between the minimum pumping rates that occur in the winter months, and the peak pumping rates that occur in the summer months. The contour interval (elevation difference) for the groundwater elevation maps is five feet. The aquifer for each depth interval was assumed to be isotropic (i.e., equal hydraulic conductivity in the east-west and north-south directions); therefore groundwater flow paths were established perpendicular to the groundwater contours. Estimating groundwater gradient along multiple groundwater flow lines and over four aquifer depth intervals provided statistically-based ranges and averages for the offsite groundwater flow velocity estimates. Computations for these average linear groundwater flow velocities are in Table C-1.

The resulting arithmetic mean and range of linear groundwater flow velocities computed for the four depth intervals are as follows:

- Shallow, 0 to 300 feet bgs: Mean of 168 feet per year, with a range of 160 to 180 feet per year.
- Intermediate-Depth, 300 to 500 feet bgs: Mean of 270 feet per year, with a range of 120 to 420 feet per year.
- Upper Deep, 500 to 700 feet bgs: Mean of 330 feet per year, with a range of 170 to 540 feet per year.
- Lower Deep, greater than 700 feet bgs: Mean of 500 feet per year, with a range of 180 to 1,200 feet per year.

The groundwater flow rates are based on groundwater elevation contour maps developed from a single round of groundwater measurements collected in May 2016. This round of measurements represents the most complete data set available for this area. The estimates assume average hydraulic conductivities and effective porosities applied as constants across the entire depth zone. Estimated seepage velocities will vary based on changes in short-term or long-term well field pumping rates over time (i.e., changes to

groundwater elevations and hydraulic gradients), the location within the measured groundwater flow field, and from spatial and temporal variations in hydraulic conductivity and porosity. The values are horizontal average linear velocities that do not represent vertical (i.e., downward or upward) movement of groundwater that may occur from vertical hydraulic gradients.

For South Farmingdale Water District Plant 6, based on hydrogeological calculations in the screened depth interval of 500 to 700 feet bgs, groundwater is estimated to flow at the mean velocity of 250 feet per year in this interval could travel the distance from the currently known edge of the plume to South Farmingdale Water District Wells 6-1 and 6-2 (a distance of 2,800 feet) in approximately 11 years. However, plume migration in this area would be hindered by the operation of South Farmingdale Water District Plant 3 and New York American Water (both with VOC treatment), and it is unclear whether or not the plume would ever reach South Farmingdale Water District Wells 6-1 and 6-2. Because of uncertainty inherent in this type of calculation, outpost wells are in place to provide five-year advance notice so that installation of treatment at these supply wells can be initiated, if necessary.

Massapequa Water District Wells 4 and 5 are screened in the depth intervals of 500 to 700 feet bgs (Well 4) and the greater than 700 feet bgs (Well 5). It is unclear whether or not the VOC plume would be able to reach these wells because the migration would be hindered by the pumping of multiple water supply wells at South Farmingdale Water District Plants 3 and 6 and New York American Water – Seamans Neck Road Facility that operate between the plume edge and Massapequa Water District wells. The impact of South Farmingdale Water District and New York American Water groundwater pumping on limiting continued plume migration to the south toward Massapequa Water District wells is indicated by the low point in the groundwater contours shown in Figures 3-11 and 3-12 in the area of Southern State Parkway. The arc in the 35-foot groundwater elevation contour on Figure 3-11, near well South Farmingdale Water District Well 3-1, indicates that groundwater is converging towards that well. The closed-loop, 25- and 30-foot groundwater elevation contours on the figures suggest that groundwater from the north and south is converging towards South Farmingdale Water District Plant 6 and New York American Water wells. Groundwater flow in this area is based on groundwater elevation data at wells BPOW 6-1 through BPOW 6-6, north of Southern State Parkway, and the 35-foot groundwater elevation contours south of Southern State Parkway on both figures. Figures 3-11 and 3-12 show ridges of higher groundwater elevations at well BPOW 6-4 (500 to 700 feet bgs zone) and wells BPOW 6-3 and BPOW 6-6 (greater than 700 feet bgs zone). Groundwater north of these ridges will flow primarily to the north, and groundwater south of these ridges will flow to the south. These contours indicate that some portion of groundwater is being captured by the South Farmingdale Water District and New York American Water wells that are located several thousand feet north of Massapequa Water Supply Wells 4 and 5.

A hypothetical scenario was developed to consider potential plume travel times to Massapequa Water District Water Wells 4 and 5 in the event that South Farmingdale and New York American Water wells in this area were no longer operating. To develop this scenario, assumptions used by the USGS in their

baseline modelling efforts for the Magothy aquifer (Figure 5 in Misut, 2014) were used to estimate the hydraulic gradient (0.0017 foot per foot). The average linear velocities for the 500 to 700 feet bgs zone (for Massapequa Water District Well 4) and greater than 700 feet bgs zone (for Massapequa Water District Well 5) are 221 and 305 feet per year, respectively. The result of these calculations is that groundwater could travel from the current edge of the plume to these wells (distances of 7,600 feet and 7,300 feet, respectively) within 24 to 34 years. Because of uncertainty inherent in this type of calculation, outpost wells are in place to provide five-year advance notice so that installation of treatment at these supply wells can be initiated, if necessary.

| **Maximum** | | | | | | | 175.60 | | | | | | | 422.92 | | | | | | | 538.58 | | | | | | | 1223.07 | |

| Input Parameters by Aquifer Depth | | |
|---|---|---|
| K 0-300 = | 50 | ft/day |
| n 0-300 = | 0.25 | $ft^3/ft^3$ |
| K 300-500 = | 78 | ft/day |
| n 300-500= | 0.25 | $ft^3/ft^3$ |
| K 500-700 = | 87 | ft/day |
| n 500-700 = | 0.25 | $ft^3/ft^3$ |
| K GT 700 = | 120 | ft/day |
| n GT 700 = | 0.25 | $ft^3/ft^3$ |

**Overall average linear velocity (all aquifer depths combined)**

| | | |
|---|---|---|
| Average = | 368.73 | ft/year |
| Minimum = | 115.48 | ft/year |
| Maximum = | 1223.07 | ft/year |
