19. ABSTRACT (Continue on reverse if necessary and identify by block number)  This document provides a compilation and review of assessment results for the Chicora Tank Farm, Charleston, South Carolina. Based on the assessment, it is apparent that releases of petroleum constituents have had little effect on groundwater quality as measured using BTEX, TPH and PAH analyses. However, detectable levels of heavy-fraction hydrocarbons are present in site groundwaters. Significant levels of petroleum residues in soil appear to be limited to sediment in the spill containment pond.

## **ACKNOWLEDGEMENTS**

The Contamination Assessment Study team thanks the many people at the Chicora Tank Farm, Naval Supply Center Charleston, and the Southern Division Naval Facilities Engineering Command, who cooperated to make successful completion of this study possible. We would also like to gratefully acknowledge the efforts and assistance of the Naval Energy and Environmental Support Activity.

## EXECUTIVE SUMMARY

This document summarizes analytical and field data collected during a preliminary contamination assessment, four quarterly groundwater monitoring events, and a sediment sampling and analysis events at the Chicora Tank Farm (CTF), a below ground petroleum tank farm operated by the Naval Supply Center in Charleston, South Carolina.

Assessment activities for the Chicora Tank Farm (CTF) were performed at the request of the Department of the Navy, Southern Division, Naval Facilities Engineering Command (Daryle Fontenot, Engineer in Charge) under contract number N62467-87-D-0650, and according to Statement of Work dated 25 January 1991. The CTF Installation Work Plan for additional assessment activities above and beyond those assessment activities previously conducted for the Preliminary Contamination Report/ Corrective Action Plan included the following activities: 1) the collection and analysis of sediment samples from the spill containment pond; 2) the removal and disposal of free-phase product in manhole FD-3; and 3) the collection and analyses of groundwater samples from the groundwater monitoring wells and the underground drainage system for four consecutive quarters.

Based on this assessment, it is apparent that releases of BTEX, TPH and target PAH constituents from the tanks or pump rooms has had little affect on groundwater quality. However, detectable levels of heavy-fraction hydrocarbons are present in site groundwaters. Significant levels of petroleum residues in soils appear to be limited to sediment in the spill containment pond.

## CHAPTER 1. INTRODUCTION

**1.1 PURPOSE AND SCOPE.** This document summarizes analytical and field data collected during a preliminary contamination assessment, four quarterly groundwater monitoring events, and sediment sampling and analysis events at the Chicora Tank Farm (CTF), a below ground petroleum tank farm operated by the Naval Supply Center in Charleston, South Carolina. The site location is illustrated in Figure 1-1. All data has been reported previously in the following five submittals:

- \* *Preliminary Contamination Assessment Report/Contamination Assessment Plan for Chicora Tank Farm, Charleston Naval Shipyard, Charleston, South Carolina (PCAR/CAP), dated July 1992,*
- \* *Installation Work Plan and Results of First Quarterly Monitoring Event for Chicora Tank Farm, Charleston Naval Shipyard, Charleston, South Carolina, dated May 1993,*
- \* *Results of Second Quarterly Monitoring Event for Chicora Tank Farm, Charleston Naval Shipyard, Charleston, South Carolina, dated August 1993,*
- \* *Results of Third Quarterly Monitoring Event for Chicora Tank Farm, Charleston Naval Shipyard, Charleston, South Carolina, dated November 1993, and*
- \* *Results of Fourth Quarterly Monitoring Event for Chicora Tank Farm, Charleston Naval Shipyard, Charleston, South Carolina, dated February 1994.*

This Contamination Assessment Report for the Chicora Tank Farm (CTF) was prepared at the request of the Department of the Navy, Southern Division, Naval Facilities Engineering Command (Daryle Fontenot, Engineer in Charge) under contract number N62467-87-D-0650, and according to Statement of Work dated 25 January 1991. The CTF Installation Work Plan, as presented in the KEMRON's previous reports included the following activities: 1) the collection and analysis of sediment samples from the spill containment pond; 2) the removal and disposal of free-phase product in manhole FD-3; and 3) the collection and analyses of groundwater samples from the groundwater monitoring wells and the underground drainage system for four consecutive quarters.

The purpose of quarterly groundwater monitoring was to develop a database of groundwater quality data. Additional soils data was generated to assess petroleum residues in site soils and spill containment pond sediments.

**1.2 REPORT ORGANIZATION.** Chapter 2 of this document includes site background data and information on the general area. Chapter 3 includes a discussion of the preliminary contamination assessment at the site, including specifics of soil boring and monitoring well installation and soil gas/traces surveys. Chapter 4 includes a summary of analytical and field data generated during the quarterly monitoring program for assessment of groundwater, and Chapter 5 includes a summary of analytical and field data generated for assessment of site soils. Conclusions are presented in Chapter 6.

## CHAPTER 2. SITE DESCRIPTION

**2.1 STUDY AREA.** CTF is a 23-acre site which formerly supplied fuel and lubricants to the Naval Shipyard. CTF is located approximately 500 yards west of the Charleston Naval Shipyard (Figure 1-1). The area surrounding CTF is a mature urban neighborhood with commercial, public, and residential land uses.

Commercial areas are located primarily along the south and southwest sides of the tank farm. Major commercial enterprises include a transmission shop and a trucking facility southwest of the site. A cargo container storage facility is located south of CTF, beyond Clements Ferry Road. The Norman C. Toole Middle School is located west of and adjacent to the site. Residential homes occupy properties east of the site, beyond Chicora Avenue, and north of the site, beyond the drainage slough.

**2.1.1. Underground Storage Tank Farm.** The tank farm consists of six fuel storage tanks which are covered with soil (3-5 feet thick at the apex), such that each tank appears to be a small hillock. Tanks have working capacities of 50,000 bbl and 27,000 bbl. The locations of these tanks are shown in Figure 2-1. Each tank interior is approximately 25 ft. in height and is constructed with 24 in. reinforced concrete walls and a domed roof. Connected to each tank is a pump room, measuring approximately 23 ft. x 24 ft. x 27 ft. The exterior of each tank is coated with 3 inches of gunite to minimize leakage of groundwater into the tanks.

**2.1.2. Subsurface Drainage System and Spill Containment Pond.** To control groundwater flow and collect spills within the tank farm area, a subsurface drainage system and containment pond were built. The subsurface drainage system is a network of "french drains" which consist of an underground 18-in. diameter main drainage pipe which underlies the long axis of the site and discharges to the spill containment pond. Connected to this drain are a series of 12-in. diameter drains which extend around or under each tank. As the water table fluctuates, groundwater seeps into the perforated tank drain pipes where it is channeled to the main drainage pipe. Water then flows through this pipe and discharges into the spill containment pond located on the northwest portion of the property.

In addition, a surface drainage ditch located along the northeast boundary of the tank farm collects surface waters and routes these waters to the spill containment pond. All water which enters the pond then bypasses an inoperable oil skimmer system and flows into the marshy tidal slough adjacent to the northern boundary of the site. Both the drainage ditch and the pond are lined with 30-mil polyethylene.

Three manholes, designated as FD-1, FD-2, and FD-3, Figure 2-2, provide access to the underground drain system. The 12 in. diameter pipe drain laterals located beneath tanks M, N, and O connect with the main drainage line at manhole FD-1, the southernmost and upgradient manhole. The 12 in. diameter pipe drain that is located beneath tank P connects with the main drainage line at manhole FD-2, the central manhole. The drain lateral beneath tank K connects at the main drainage line at manhole FD-3, the northernmost manhole. Approximately 40 ft. northwest of FD-2, a lateral beneath tank L connects with the main drainage line; however, no surface access is available at this location.

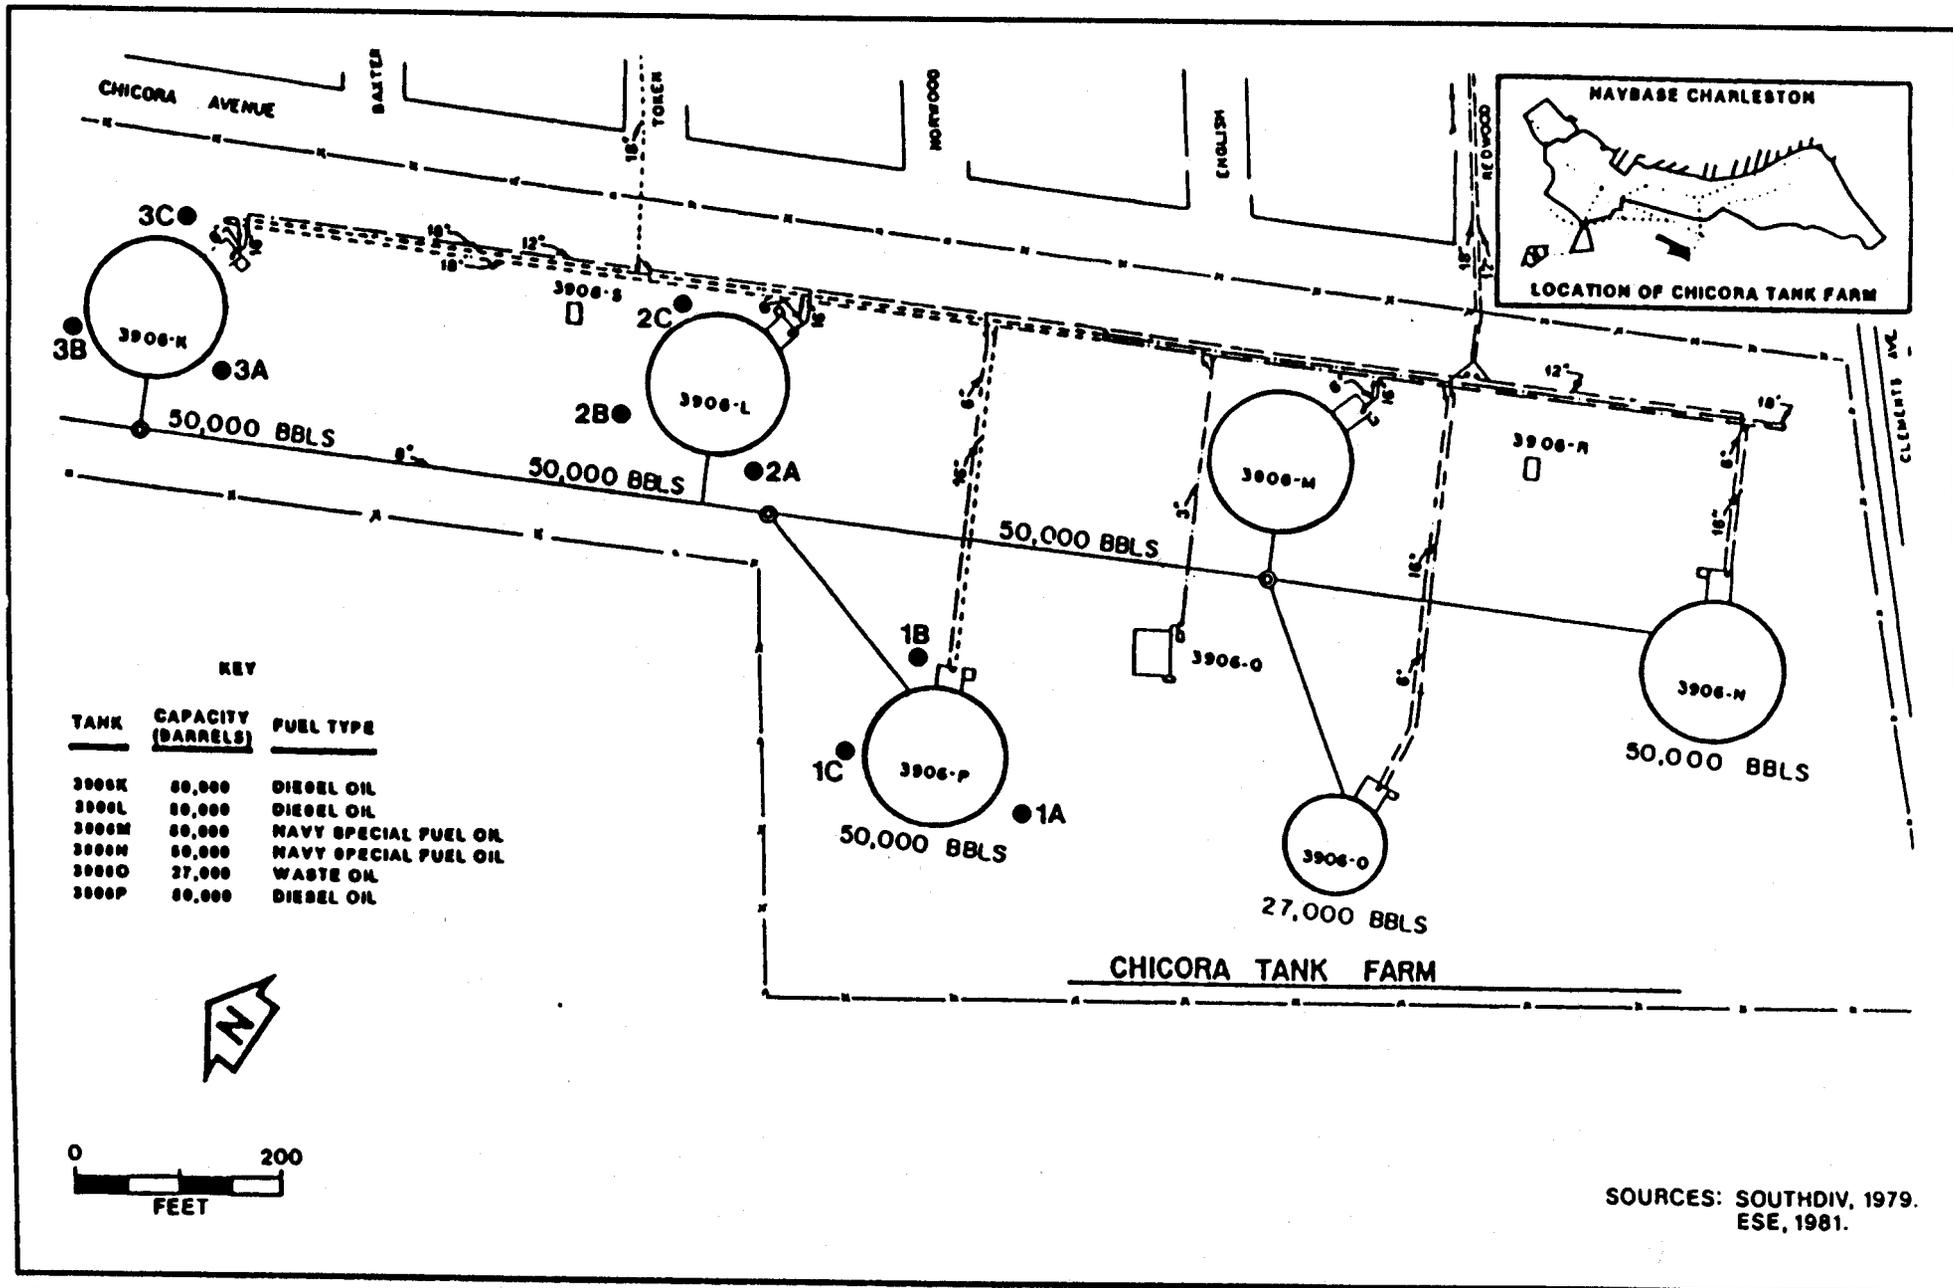

Figure 2-1. Site map showing tank and piping locations. ESE soil borehole locations are also indicated.

2-3

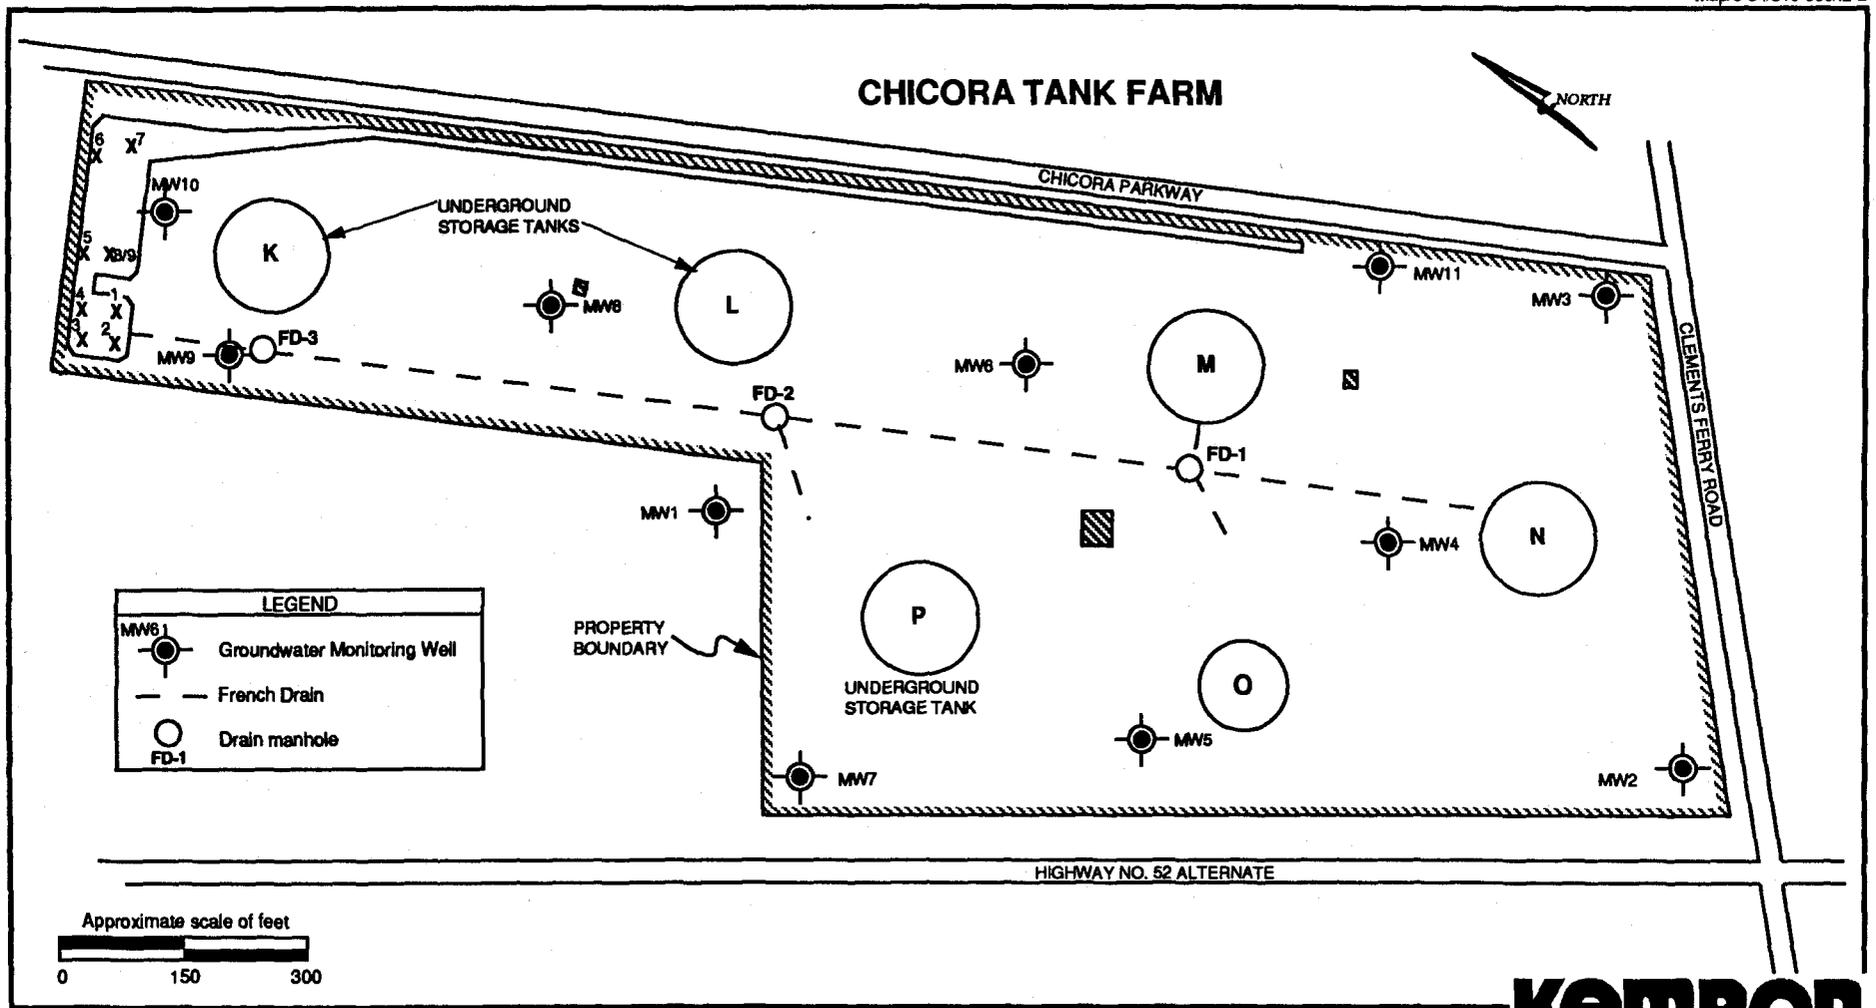

Figure 2-2. Site map showing french drain manhole and monitoring well locations.

**2.1.3. Shallow Groundwater Monitoring Wells.** Eleven water table groundwater monitoring wells, MW-1 through MW-11, are present at the site. The locations of these wells are shown in Figure 2-2. These wells were constructed in June 1990, during preliminary contamination assessment activities, to a depth approximately 17 ft. below ground surface. They are used to monitor groundwater in the uppermost aquifer. Placement and construction of wells is further described in Section 3.4 below.

## **2.2 CHARACTERISTICS OF STUDY AREA.**

**2.2.1 Topography and Physiography.** The Charleston Naval Shipyard, CTF, and surrounding areas are located on the eastern edge of a low, narrow peninsula between the Ashley and Cooper Rivers. Topography is typical of South Carolina's lower coastal plain, with low-relief plains drained by meandering streams and rivers flowing toward the coast past occasional marine terrace escarpments. Elevations around CTF and the Shipyard range from approximately 20 ft. above Mean Sea Level (MSL) in the inland portions of the base, to sea level along the Cooper River. Although the southern end of the base was originally tidal marsh drained by Shipyard Creek and its tributaries, over the past 70 years, the marsh has been filled. Most of the base lies within the 100-yr flood zone (less than 10 ft. MSL).

**2.2.2. Surface Hydrology.** The southeastern portion of the shipyard is drained by Shipyard Creek while Noisette Creek drains the northern portion. Both creeks are tributaries of the Cooper River. Shipyard Creek is a small tidal tributary, approximately 1.5 miles in length, which flows in a southeasterly direction along the southwestern boundary of the base into the Cooper River. Noisette Creek is a tidal tributary, approximately 2.5 miles in length, which flows nearly due east from its headwaters in the City of North Charleston, across the northern portion of the base, and into the Cooper River.

Surface drainage over the remainder of the base discharges directly into the Cooper River which flows in a southerly direction to Charleston Harbor. Runoff from CTF flows into a shallow drainage ditch running along the northwestern edge of the site and eventually drains into a retention pond located on the far northwestern end of the property. The retention pond is connected to an adjoining marshy tidal slough that drains into the Cooper River.

**2.2.3. Regional Geology.** Geology of the Charleston area is typical of the southern Atlantic Coastal Plain. Surface exposures at the shipyard, in those limited areas which remain undisturbed, consist of recent and/or Pleistocene-age sands, silts, and clays of high organic content. These surface soils are underlain by a clastic calcareous clay known as the Cooper Marl. The Cooper Marl is, in turn, underlain by the Santee Limestone.

**2.2.4. Soils.** Surface soils at the base and the CTF have been extensively disturbed. Native soils consist of the fine-grain sand, silty sand, clayey sand, sandy clay, and clay that are typical of a terrigenous tidal marsh environment. Much of the southern portion of the base and tank farm area has been filled using dredged spoil consisting primarily of an unsorted mixture of sands, silts, and clays. Fill material at the tank farm is predominantly fine to medium grain clayey sand which has been graded into mounds over the fuel tanks.

**2.2.5. Hydrogeology.** Two distinct aquifers exist beneath the CTF and surrounding areas. A deep, confined aquifer is located in the Santee Limestone and a shallow water table aquifer is located within the near-surface sediments. Both the shallow aquifer and the Santee Limestone aquifer function as

sources of potable water. However, the shallow aquifer is not developed either at or in the vicinity of CTF and the naval base. Deeper water from the Santee Limestone (in the vicinity of CTF and the naval base) is not suitable for potable supply due to concentrations of dissolved solids ranging from 1,000 to 1,500 ppm. The Santee is used both on base and nearby for non-potable purposes.

The Cooper Marl, in the Charleston area, is essentially impermeable and acts as an upper confining layer for the Santee Limestone aquifer. The top of the Santee Limestone aquifer has a groundwater potentiometric elevation of approximately 15 ft. MSL. The hydraulic gradient in the area is generally to the southeast. Water from the confined aquifer of the Santee Limestone formation has an upward potential through the Cooper Marl. This upward potential protects the Santee from near-surface contamination.

Groundwater in the shallow aquifer surrounding CTF flows generally to the east. However, beneath CTF proper, the shallow aquifer usually flows to the centrally located french drain. Exceptions occur during low water table conditions. At such times, influence of the french drains is less and groundwaters beneath the southwest corner of CTF may reverse direction and move off-site.

**2.3 SITE HISTORY.** The fuel storage tanks at CTF were constructed in 1943 to hold heavy No. 6 fuel oil for use in boilers of Navy ships. Originally, all tanks were utilized for No. 6 storage except tank O, which was designed and utilized to hold waste oil. No. 6 fuel oil stored at CTF was replaced with Navy Special Fuel Oil (NSFO), another heavy fuel oil, in approximately 1960. NSFO stored in tanks K, L, and P was replaced in 1969 with Navy Distillate, a lighter diesel-like fuel oil. Tanks N and M continued to hold NSFO. Eventually, Navy Distillate was replaced with Diesel Fuel Marine (DFM). Tank N was taken out of service in July 1988 due to major electrical problems which continue to render the tank unusable. Tank M was taken out of service in March 1990 but remains serviceable. Currently, none of the tanks at the farm are in use; all tanks are closed.

Because the tanks were originally designed to hold heavy No. 6 fuel oil, which is too viscous to seep through concrete, the interior walls of the tanks were never lined to prevent seepage. Soon after the change to Navy Distillate, leakage of fuel through the tank walls into the pump rooms of tanks K, L, and P was observed. In 1986, SOUTHDIV commissioned Environmental Science and Engineering (ESE), Inc. to conduct a contamination assessment to determine whether or not the observed fuel seepage had resulted in significant soil and/or groundwater contamination around the tanks. Three soil samples were retrieved from each of nine boreholes drilled within approximately 40 ft. of tanks K, L, and P at depths of 10-15 ft. Borehole locations are shown on Figure 2-1.

Total petroleum hydrocarbons (TPH) and benzene, toluene, and xylenes (BTX) assays performed on these samples failed to detect any evidence of petroleum contamination. Water samples from each of the nine boreholes were examined for signs of petroleum contamination. The water samples reportedly exhibited no petroleum odor and only the water sample from ESE borehole #3B, located northwest of tank K, had a noticeable sheen. Based on these results, ESE concluded that the tanks were not releasing fuel into the surrounding soils.

A fuel spill reportedly occurred in 1986, when tank P was filled beyond capacity. The quantity of fuel released is unknown. The fuel reportedly flowed down the eastern slope of tank P.

On 11 August 1988, NSC personnel observed free-phase petroleum product in one of the access manholes of the french drain system at CTF. Samples were collected and laboratory analysis

confirmed the presence of a combination of DFM and NSFO. Following this discovery, a site investigation was initiated by SOUTHDIV at CTF to determine the need for a more detailed contamination assessment. The investigation was limited to inspection of the site; review of existing documents and drawings; and interviews and discussions with NSC and SOUTHDIV personnel.

During site inspections on 19 and 28 September 1988, free-phase petroleum product was observed on the water in each of the three french drain access manholes. Approximately two inches of product were observed in manholes FD-2 and FD-3, while only a petroleum sheen was visible in manhole FD-1. The concrete walls of manholes FD-1 and FD-2 appeared to be coated with a dark, oily sludge below the water surface. A light sheen was visible on the surface of the retention pond during these inspections, and stressed vegetation was observed surrounding the pond. Upon completion of the investigation, SOUTHDIV recommended that a preliminary contamination assessment be conducted to gauge the extent of subsurface contamination at CTF.

### 3. PRELIMINARY CONTAMINATION ASSESSMENT RESULTS

KEMRON Environmental Services, Inc. was contracted to perform the Preliminary Contamination Assessment at the CTF. Assessment activities included a soil gas survey, tracer survey, installation of soil borings and groundwater monitoring wells, sampling and analysis of subsurface soil samples, sediment samples, groundwater samples, and surface water samples. Investigation of site hydrogeology was also conducted.

**3.1 TRACER SURVEY.** A tracer survey and analysis was performed around the fuel storage tanks and associated piping in February and March 1990 by Tracer Research Corp. (TRC). The survey was initiated by the addition of difluorodibromomethane (DDM) tracer to each tank at the tank farm. Enough tracer was introduced to each of the tanks to make the concentration in the tanks approximately 10 ppm, had the tanks been filled near to capacity. Actual concentrations were higher. Soil vapor sampling was initiated after a three-week waiting period, which allowed the tracer time to diffuse throughout the storage and transport system and migrate through any leaks in the concrete tanks and associated piping systems.

For the survey, steel Schedule 80 1 in. OD pipes, capped with steel drive points, were driven into the bermed soils at 25 ft. intervals surrounding each tank. Each probe had an effective detection radius of approximately 10 to 12 ft. In order to maximize coverage and minimize testing time, sampling depths near the tanks were staggered. A soil-gas sample was retrieved at a depth of approximately six feet at every sampling location; a second sample was drawn from a depth of approximately twelve feet at every other sampling location. Steel drive points were also driven into the ground to depths ranging from one to three feet below grade in the vicinity of the fuel system piping at 25 ft. intervals along the entire length of the piping system. The tracer survey sampling locations are illustrated in Figure 3-1.

A vacuum pump was attached to each sample point with a hose and clasp. A vacuum was subsequently drawn on each sample point for approximately three minutes to extract gases present within the soils. Samples were extracted from each drive point stem by inserting an air-tight, pre-labeled, dedicated, hypodermic syringe through the attached hose. Trapped soil gases were collected within the syringe barrel when the syringe plunger was pulled back. Sample locations were recorded with  $\pm 1$  ft. accuracy. Immediately following sample collection, the contents of each syringe were injected into a gas chromatograph (GC) connected to an electron capture detector (ECD). Sample results were available approximately ten minutes after injection.

The tracer survey consisted of a total of 351 soil gas samples retrieved from 274 sample point locations positioned around the tanks and along approximately 2600 ft. of piping (Figure 3-1). DDM was detected in only a limited number of samples, indicating a probable vapor leak or leaks in the ceiling of tank N. The data may also be interpreted to indicate that there are no substantial fuel leaks in the tanks or piping systems.

**3.2 SOIL GAS SURVEY.** A soil-gas survey was performed over the entire area of the Chicora Tank Farm between 27 February and 9 March 1990. Survey points were arranged on a 100 ft. grid, Figure 3-2. A 3/4-in. stainless steel slotted sample tube and drive point were driven into the ground to a total depth of 3 ft. (or to a shallower depth if the water table was encountered above 3 ft. below grade). A vacuum pump was connected to the sample tube and operated for approximately two minutes to draw organic vapors into the tube. Organic vapors in the tube were then assayed by venting the tube through a photoionization detector (PID, HNu model #161) calibrated to an

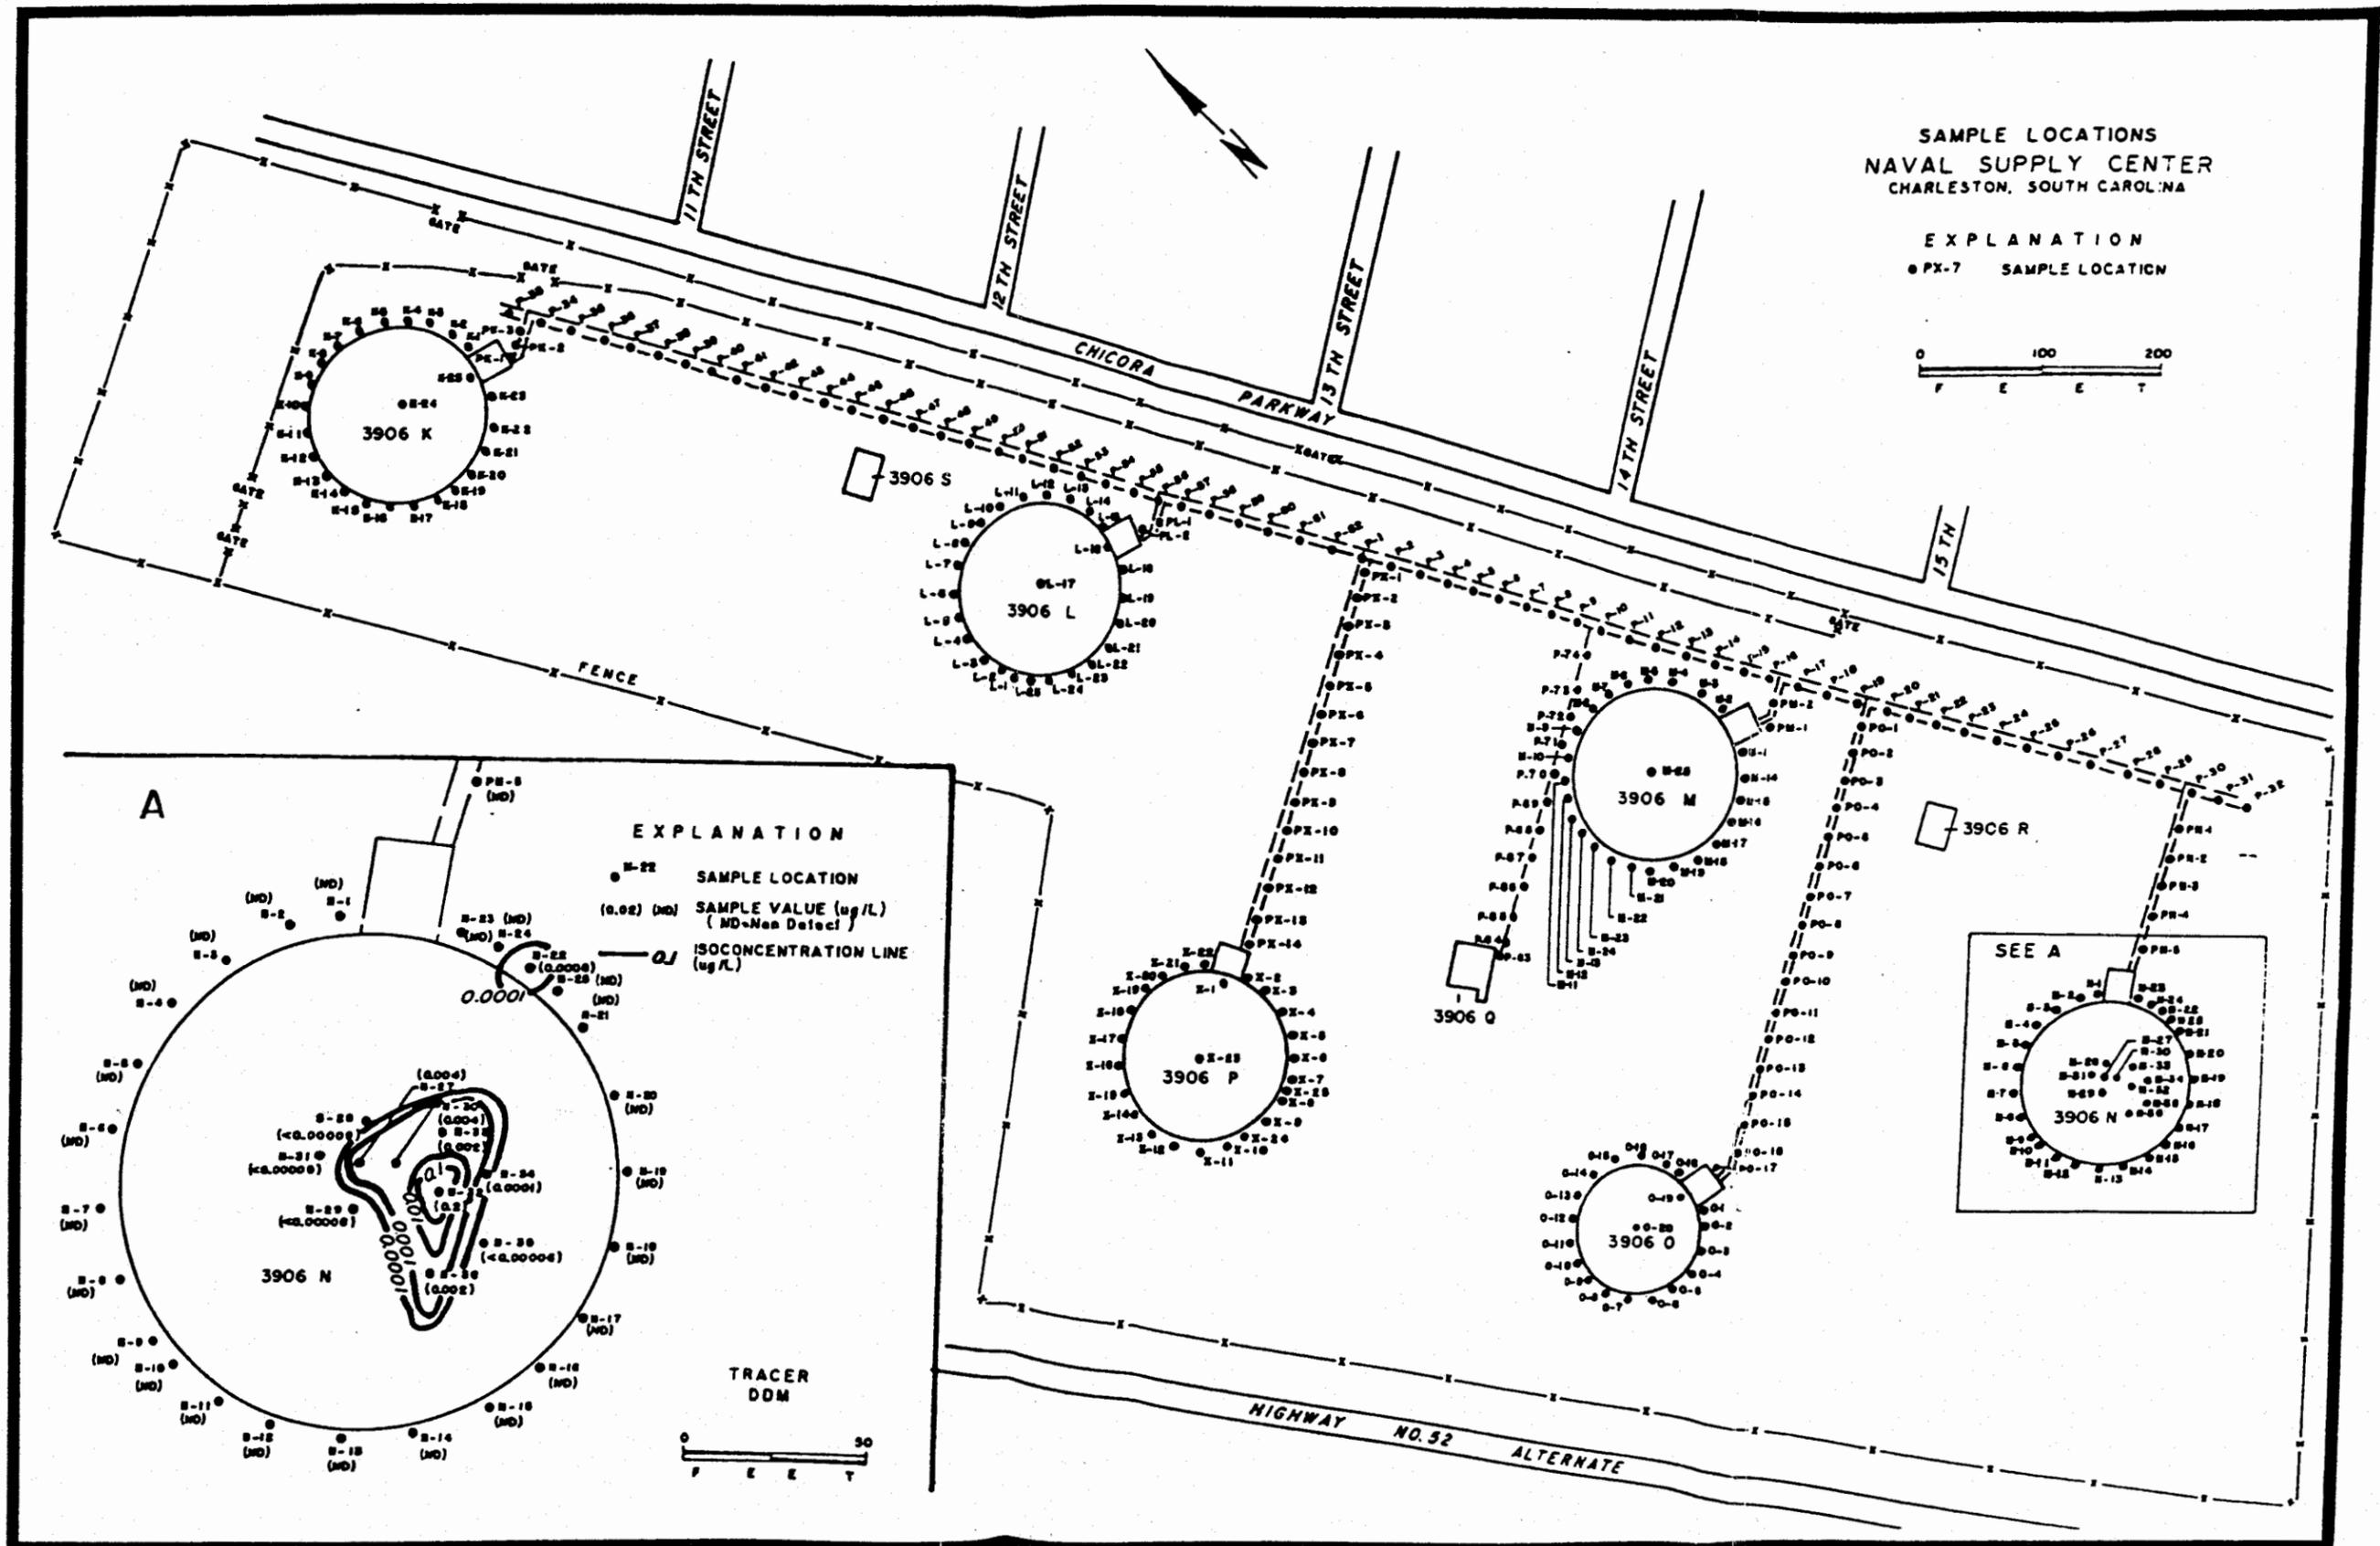

Figure 3-1. Tracer survey sample locations (from Tracer Research Corp. Report, March 1990).

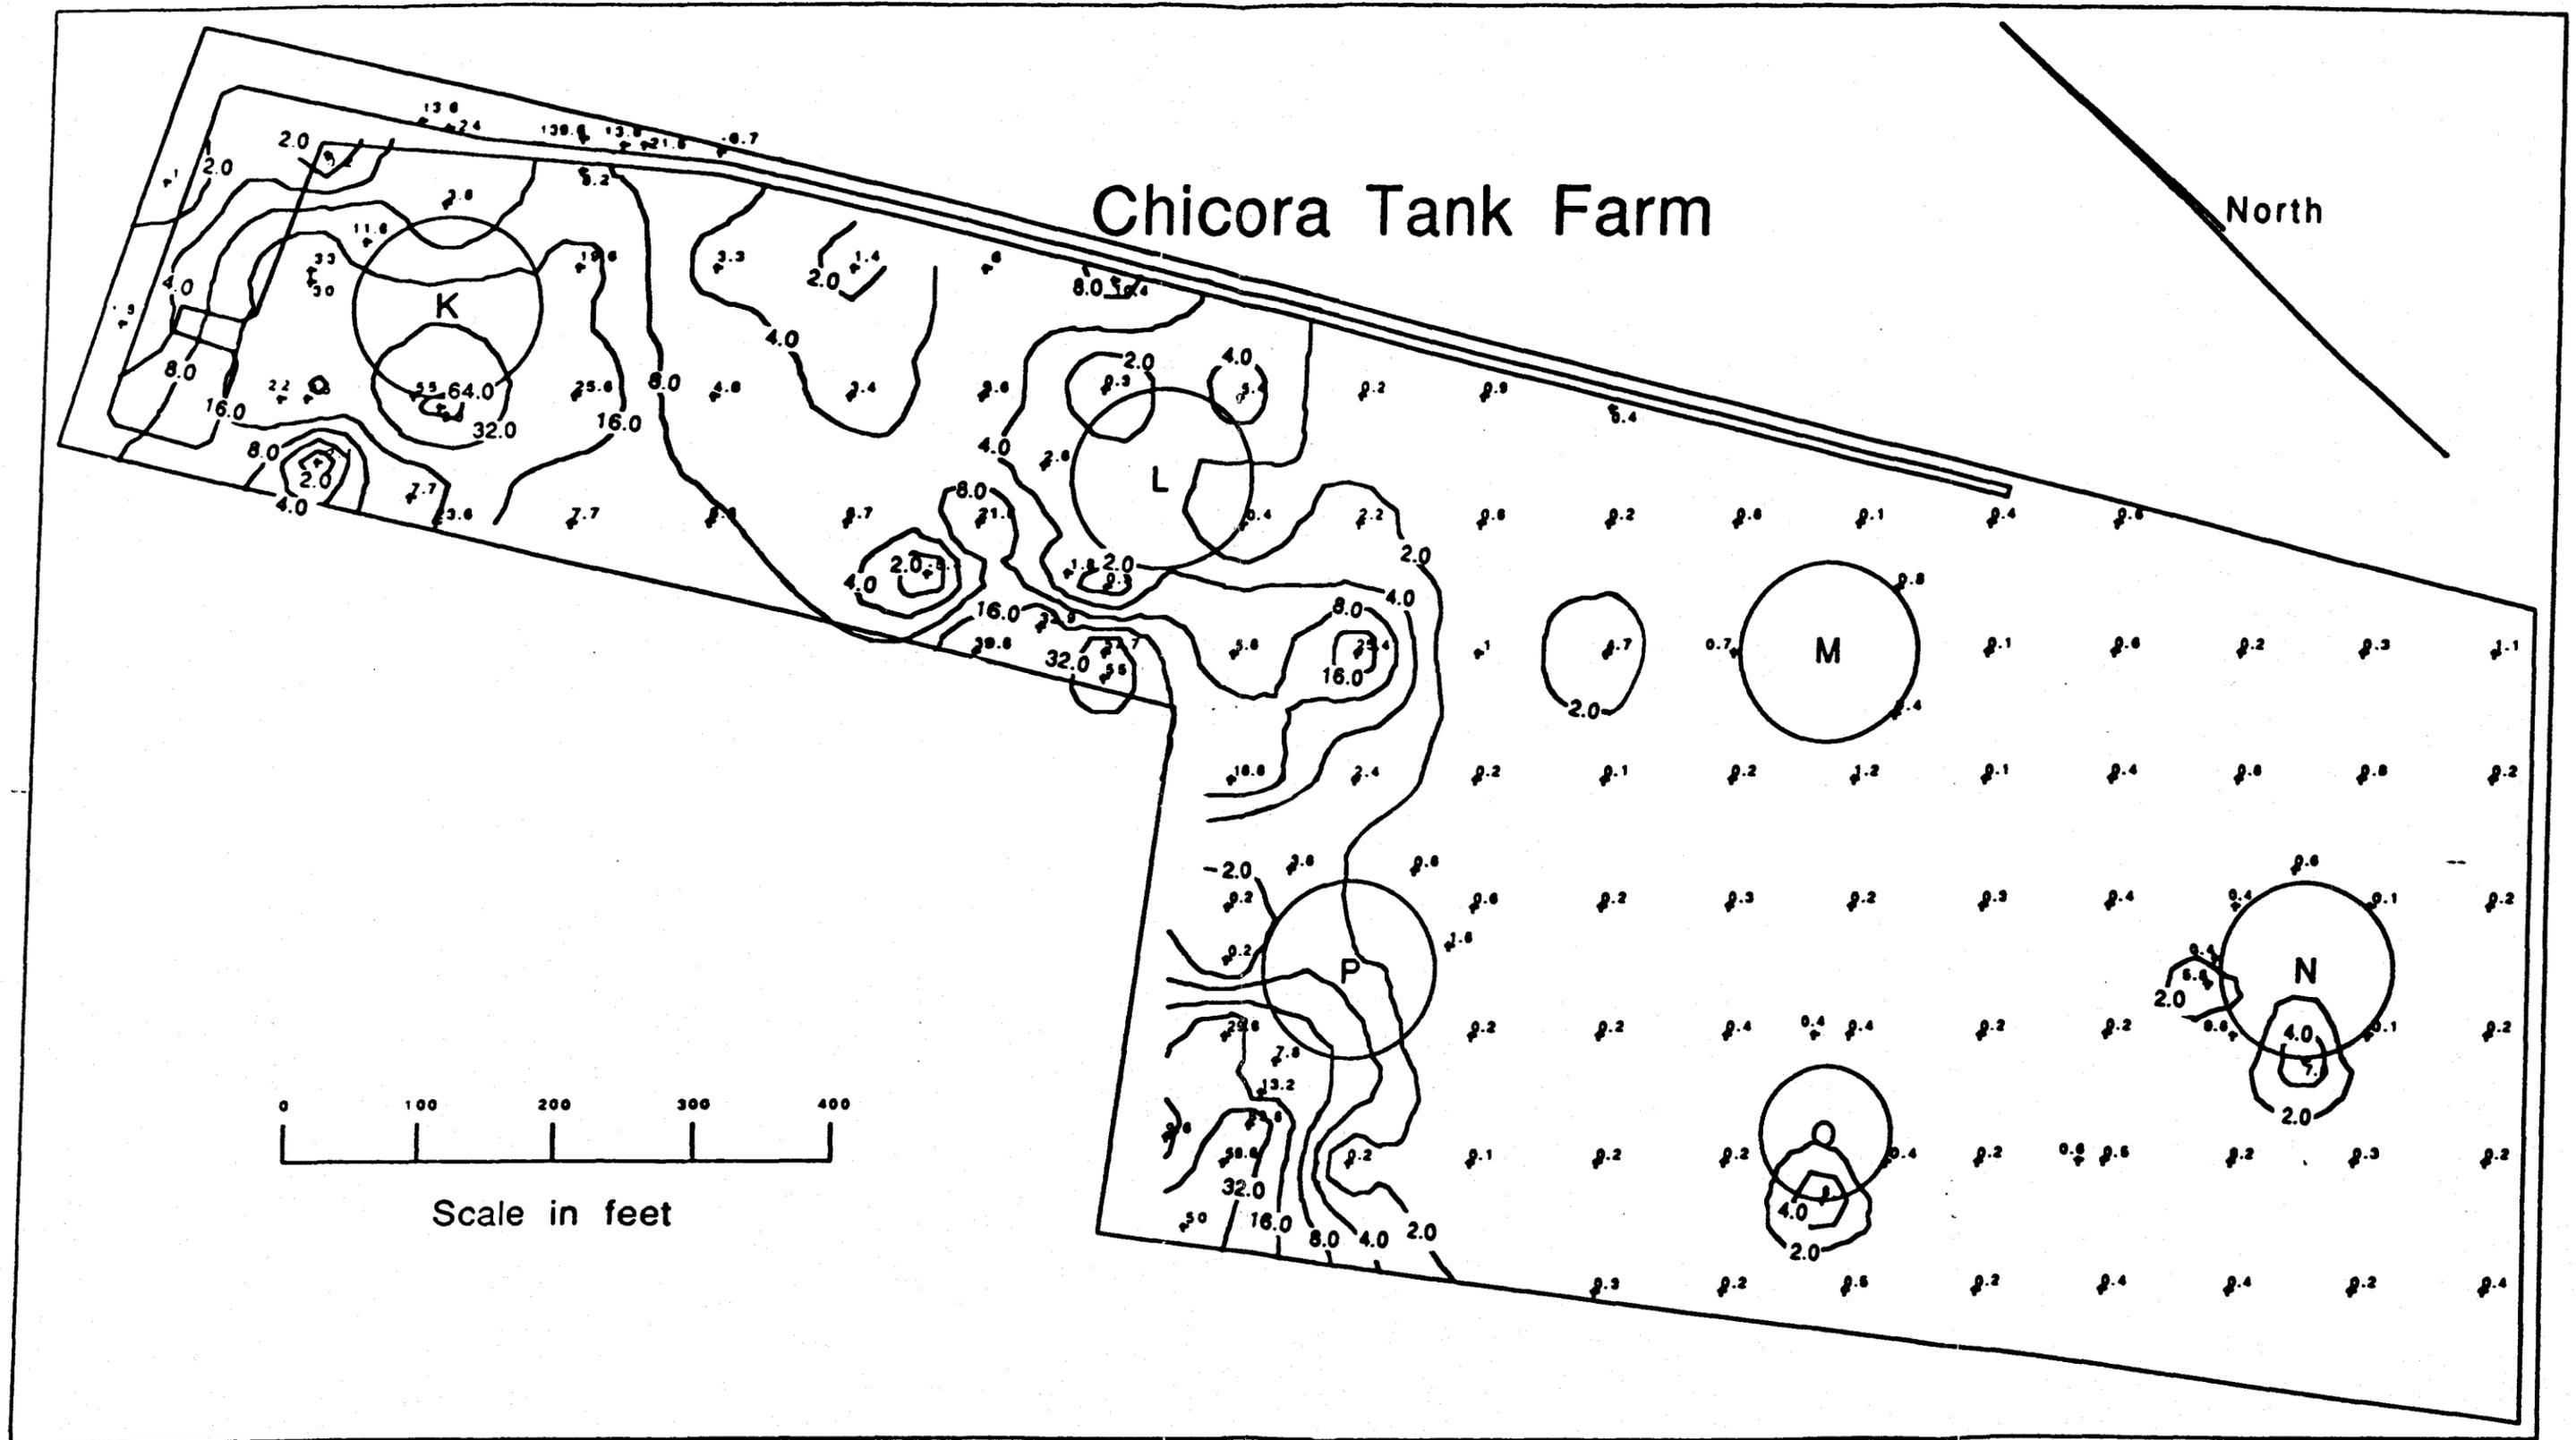

Figure 3-2. Soil-gas survey sampling locations and isopleth map.

isobutylene standard. The extent and concentration of organic vapors within soils were then determined from the soil-gas survey results. Petroleum contamination was presumed to be the source in those areas where relatively high organic vapor concentrations were detected.

Soil-gas survey results include few detections above 10 ppm. Levels as high as 57.7 and 69.6 ppm were encountered along the boundaries of the tank farm west of tanks L and P, adjacent to the Norman C. Toole Middle School. Soil-gas detections reaching concentrations of 64 ppm were also encountered immediately west of tank K near french drain manhole FD-3. A soil-gas concentration of 25.4 ppm was identified approximately two hundred feet south of tank L. Elsewhere, concentrations ranged from 0.1 to 19.6 ppm although an isolated reading of 139.6 ppm was encountered immediately adjacent to the fence along the northwest side of the site, near tank K. This reading, due to its location on the western wall of a steep drainage ditch, is assumed to be the result of hydrocarbon runoff from the nearby public road. An isopleth map of soil-gas concentrations is presented in Figure 3-2.

**3.3 SOIL TEST BORINGS.** Between 19 and 21 June, 1990, eleven soil test borings were installed by a South Carolina-certified drilling contractor at locations determined from soil-gas survey results. All locations were pre-approved by DHEC. Borings were advanced by a truck-mounted drill rig using 6 1/4-in. O.D. hollow stem auger flights to a depth approximately 7 ft. below the existing water table. Cuttings from each borehole (and soil samples retrieved from five-foot intervals within each borehole) were monitored by the field geologist for organic vapors using a PID to aid in detecting petroleum.

Soil sampling was performed in general accordance with ASTM D 1586. A standard 1.4 in. ID, 2 in. OD, split-barrel stainless steel sampler was used to collect soil samples. The sampler was first seated six inches into the ground to penetrate loose cuttings and then driven an additional foot with blows from a 140-pound hammer falling 30 inches. The number of blows required to drive the sampler the final foot was recorded as a measure of soil strength and density. Soils were removed from the sampler and inspected for soil characteristics which were then recorded on borehole-specific logs. Borehole logs are included in Appendix A. All soiled equipment was decontaminated by steam cleaning between boreholes.

Two soil samples from each boring were selected for laboratory analysis. Samples for lab analysis were selected on the basis of PID results, and visual and olfactory observation. These samples were cooled to 4°C, sealed in appropriate pre-labelled containers, and shipped to the laboratory via overnight courier. Samples were assayed for Polynuclear Aromatic Hydrocarbons (PAH), Total Petroleum Hydrocarbons (TPH), and Benzene, Toluene, Ethylbenzene, and Total Xylenes (BTEX) by EPA methods 8100, 418.1, and 8020, respectively. Chain-of-custody was documented on all samples.

**3.4 MONITORING WELL CONSTRUCTION.** Monitoring wells were installed in each soil boring described above (see Figure 2-2 for locations). Augers were left in place during well installation to prevent collapse. Each well was constructed by installing 2 in. OD Sch. 40 PVC screen and riser pipe into each boring. A 10 ft. screen with 0.01 in. slots was placed so that screen extended approximately two to three feet above and seven to eight feet below the groundwater table at the time of drilling. Riser pipe was added to the screen on nine wells to set each top-of-casing approximately two feet above ground surface. Riser pipe was added to the remaining two wells to set each well approximately 0.5 ft. below ground surface to accommodate flush-mounted well covers.

The annular space adjacent to the screened section of each well was backfilled with a sand pack. Augers were pulled up as sand was poured into the annular space to a depth approximately one foot above the screened interval. A one foot thick bentonite pellet seal was placed above the sand pack. Portland cement was poured into the annular space from the bentonite seal to the ground surface. A vertical stick-up or flush-mounted protective steel well-head protector was placed over each well. The wells were completed with locking caps. Monitoring wells were constructed as near the South Carolina Well Standards and Regulations guidelines as the extremely high water table at the site would allow. Screen and riser lengths and intervals of grout were adjusted to compensate for this high water table. Monitoring well construction diagrams are included in Appendix A.

Details on well construction are presented in Table 3-1. Note that for MW-11, the water level is above the screened interval for the 6/25/90 measurements. Subsequent water level data also show that for other wells (e.g., MW-3 and MW-6), the water levels have been above the top of the screened intervals as well. In typical groundwater monitoring programs, where petroleum or other Light Non-Aqueous Phase Liquid (LNAPL) contamination is of concern, well screens are placed across the water table so that the presence or absence of free-phase layers may be assessed. Thus, the construction of some of the wells may be considered a problem in that, if free-phase petroleum was present on the water table, it would not be able to enter the well. However, because free-phase petroleum is not present (with the exception of a sheen) in the other wells or french drains in recent monitoring events, this problem is unlikely.

**3.5 MONITORING WELL DEVELOPMENT, SAMPLING AND ANALYSIS.** Monitoring wells were developed by bailing several well volumes from each well with a decontaminated, dedicated teflon bailer. Groundwater from development activities was containerized in a 55-gallon drum, staged on-site, and subsequently properly disposed of.

Groundwater samples were obtained approximately one day after installation and development of the monitoring wells. A minimum of three well volumes was purged from each well prior to sampling. Groundwater from each monitoring well was analyzed for temperature, pH, and specific conductivity in the field. Samples were retrieved from each well with dedicated bailers and poured into properly prepared containers. Sample containers were then sealed, cooled to 4°C, and shipped to the laboratory via overnight courier. Samples were assayed for TPH, PAH, and BTEX using EPA Methods 418.1, 8100, and 8020, respectively. Chain-of-custody was documented.

The purpose of groundwater sampling was to obtain data to determine the magnitude of groundwater contamination beneath the site and to establish a baseline for the subsequent quarterly groundwater monitoring program. A benzene concentration of 0.006 mg/L was detected in monitoring well MW-2. BTEX was not detected in the remaining monitoring wells. TPH and PAH constituents were not detected in groundwater samples retrieved from the site monitoring wells. Groundwater laboratory results from monitoring well sampling activities are summarized in Table 3-2 and Appendix B. During monitoring well development, a slight petroleum sheen was observed in the groundwater recovered from monitoring wells MW-3 and MW-9. No petroleum odor was detected in groundwater recovered from the site monitoring wells.

**3.6 SURFACE WATER AND FRENCH DRAIN SAMPLING AND ANALYSIS.** Water samples were retrieved from the french drain system underlying the CTF area and from the retention pond on the northwestern portion of the property. Samples from the retention pond were retrieved by submerging clean, pre-labeled sample containers and then opening the container to collect a grab

3-7

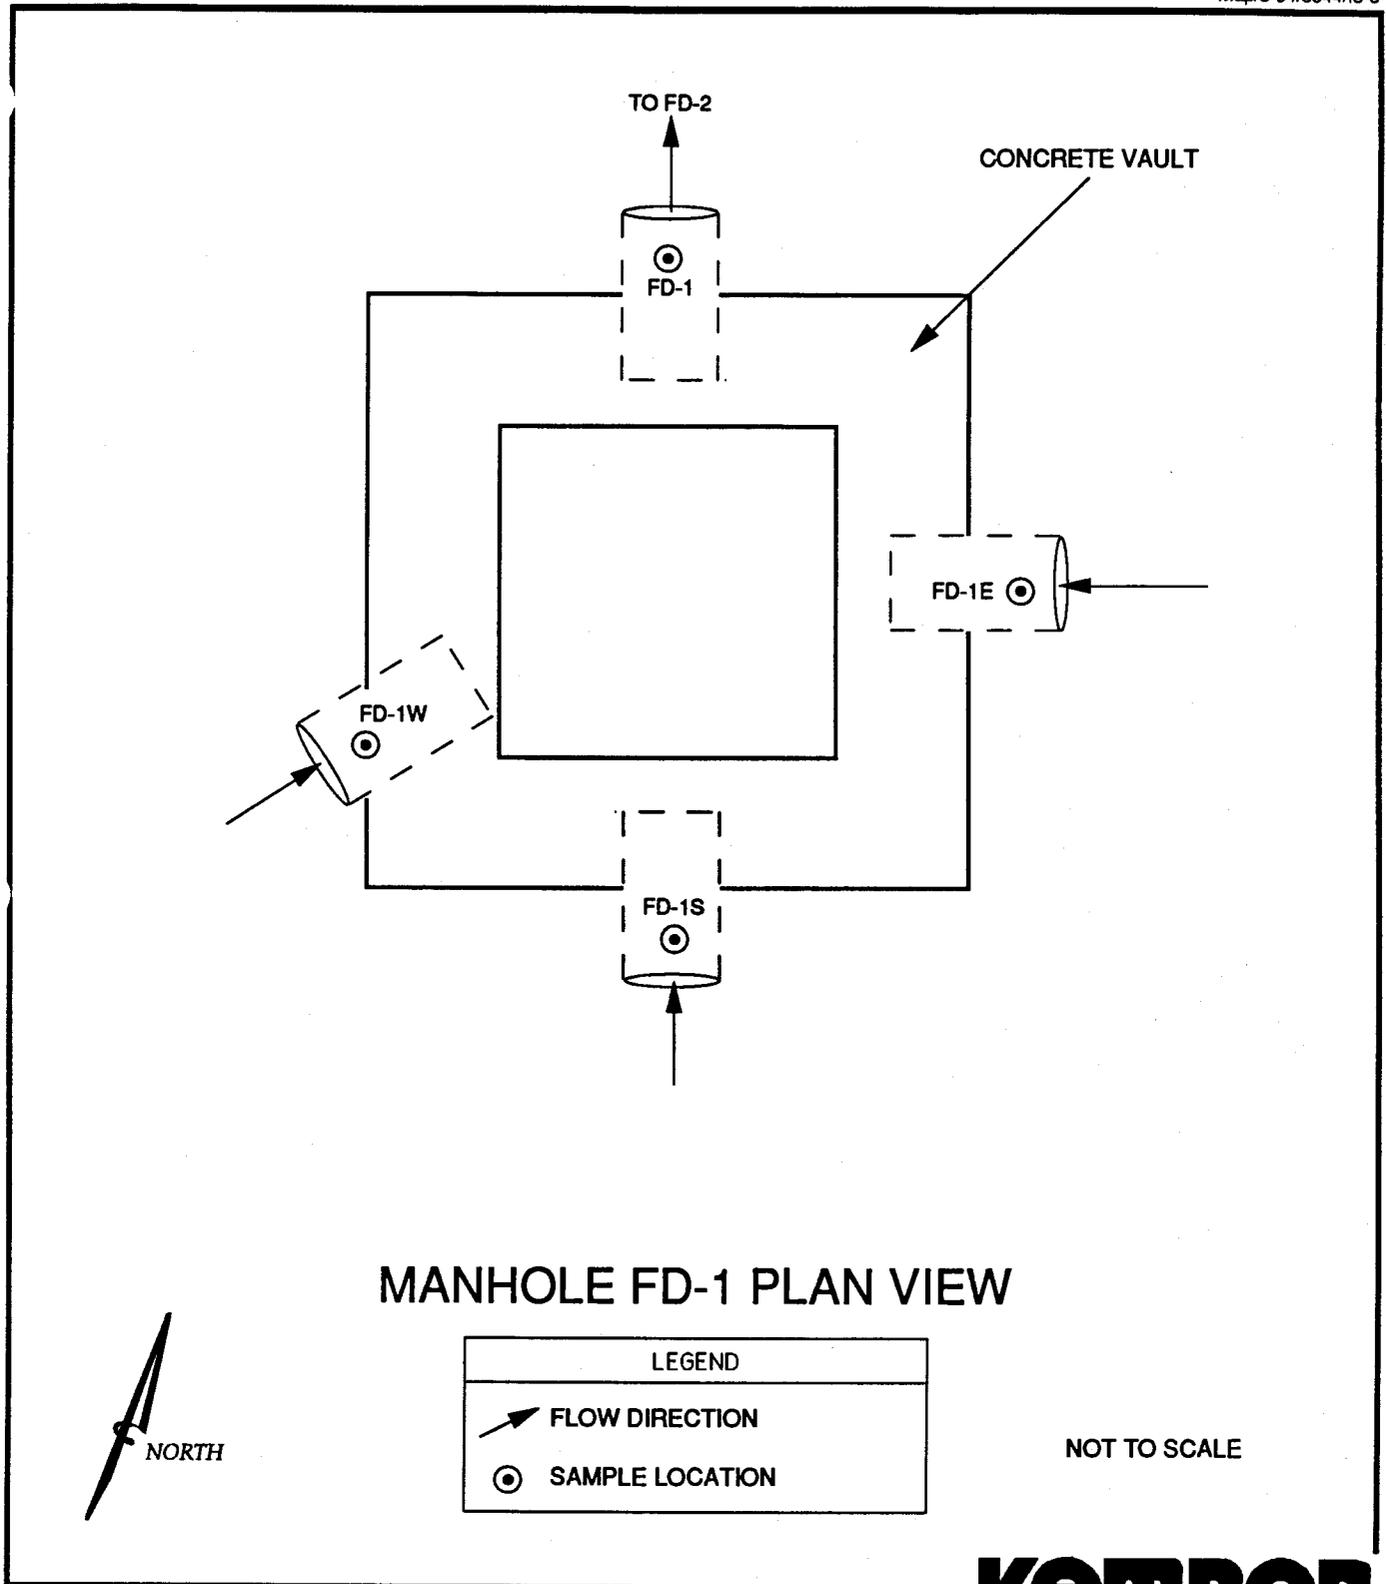

sample. French drain samples were retrieved by lowering a clean collection container into the drain and then transferring the collected sample to clean, pre-labeled sample containers. Following collection, the retention pond and french drain samples were sealed, cooled to 4°C, and shipped to the laboratory via overnight courier. Chain-of-custody procedures were documented. French drain samples were analyzed for PAH, TPH, and BTEX. Retention pond samples were analyzed for TPH and PAH. EPA methods 8100, 418.1, and 8020 were used by the laboratory for PAH, TPH, and BTEX assays, respectively.

Groundwater flowing through the french drain network present at the site was sampled in the following manner. Four groundwater samples were retrieved from manhole FD-1, three from manhole FD-2, and two from manhole FD-3. The samples retrieved from manhole FD-1 were designated FD-1, FD-1S, FD-1W, and FD-1E. The sample designated FD-1 was of waters leaving manhole FD-1. The samples designated FD-1S, FD-1W, and FD-1E were retrieved from the french drain laterals to tanks, N, O, and M, respectively. The samples retrieved from manhole FD-2 were designated FD-2, FD-2S, and FD-2W. The sample designated FD-2 was of waters leaving manhole FD-2. The samples designated FD-2S and FD-2W were of flows from manhole FD-1 and the lateral from tank P, respectively. The samples retrieved from manhole FD-3 were designated FD-3E and FD-3S. Samples FD-3E and FD-3S were from the tank K lateral and from the main drainage pipeline extending from manhole FD-2, respectively. French drain groundwater sample locations are shown on Figures 3-3, 3-4, and 3-5.

TPH and total PAH concentrations of 2 and 0.018 mg/L, respectively, were detected in sample FD-2. A TPH concentration of 2 µg/L was also detected in sample FD-2W. Extensive free-phase petroleum was observed in manhole FD-3 during collection of groundwater samples. TPH concentrations of 240 and 470 µg/L were detected in samples FD-3S and FD-3E, respectively. These groundwater samples were retrieved from beneath the free-phase petroleum present in manhole FD-3 and may have become contaminated during sampling, despite precautions. TPH was not detected in the remaining french drain samples. Neither BTEX nor PAH were detected in remaining french drain samples assayed. Petroleum detections in the french drain samples are shown on Table 3-3. Complete groundwater laboratory results are documented in Appendix B.

Two surface water samples were collected from the retention pond located on the northwestern end of the tank farm. Locations of the pond sample collection points are shown on Figure 3-4. The samples were assayed for TPH to determine the extent (if any) of petroleum contamination within the surface waters of the pond. No TPH was detected. Laboratory results from surface water assays are presented in Appendix B.

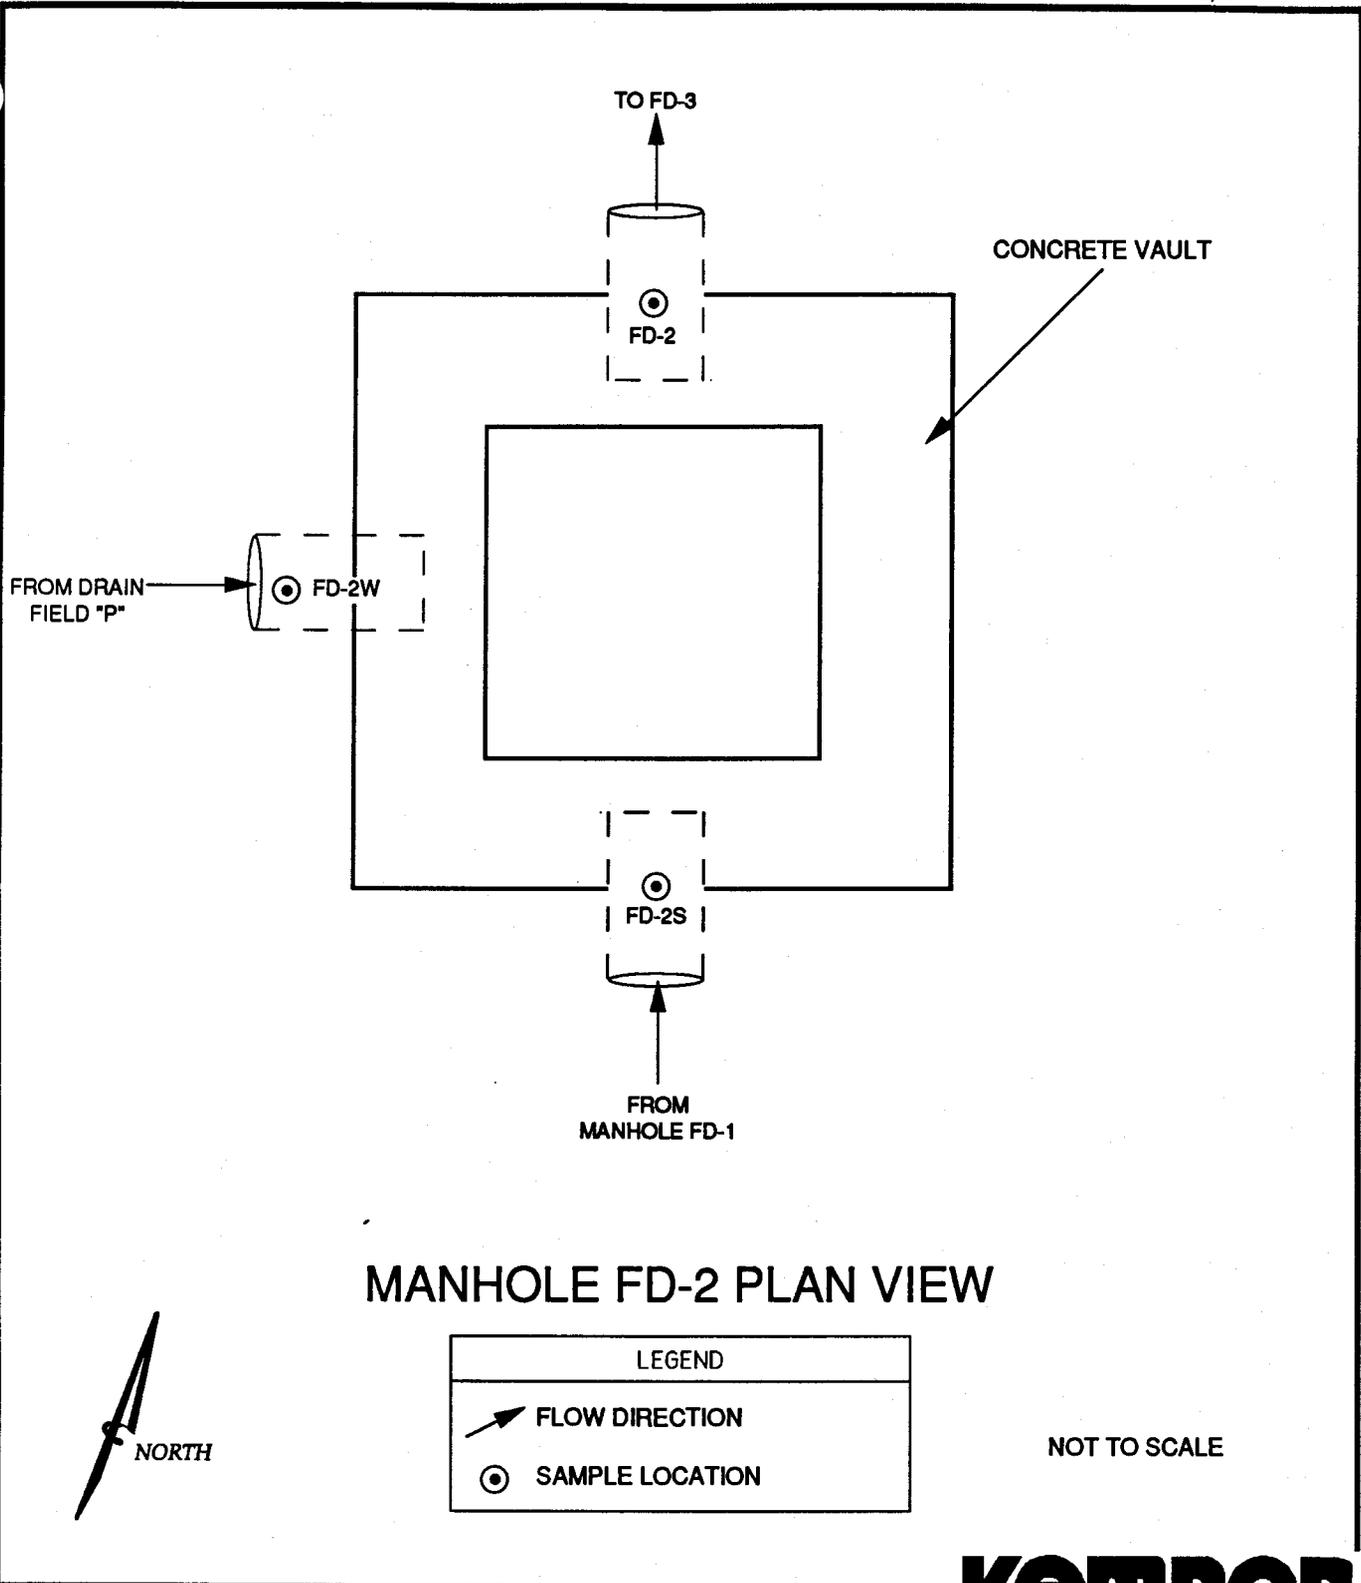

**3.7 AQUIFER TESTING.** Aquifer (slug-in) testing was performed to estimate the average, saturated horizontal hydraulic conductivity of aquifer materials near monitoring wells MW-3, MW-5, and MW-6. Testing was performed by raising the water level to the top of casing by adding tap water, then monitoring and recording the falling water level until recovery was complete. Recovery was considered to be complete when the water level stabilized near (>90%) pre-test conditions. Although a slug-out test may have been more appropriate for the wells, as the screens do extend above the water table, a useful estimation of the hydraulic conductivity can be derived.

3-12

Hydraulic conductivity values were calculated using the recovery rate and construction data from each well. Analyses were performed utilizing the method of Bouwer and Rice (1976). Aquifer flow rates were calculated using the following equation derived from Darcy's Law:

$$V = Ki/n$$

Where V = the aquifer flow rate in ft/sec

K = the average, saturated, horizontal hydraulic conductivity in ft/sec

i = the hydraulic gradient

n = the effective porosity of the aquifer

Flow rates at MW-3, MW-5, and MW-6 were calculated using measured hydraulic gradient values, well-specific hydraulic conductivity values, and estimated effective porosity values. Hydraulic gradient values of 0.0025 for monitoring well MW-3 and 0.0143 for monitoring wells MW-5 and MW-6 were used. Effective porosity was assumed to be 0.2, a conservative estimate. This value is lower than probable effective porosity values for soils observed at the site and should result in over-estimation of groundwater flow rates. Hydraulic conductivity and flow rate calculations for MW-3, MW-5, and MW-6 were previously presented in the PCAR/CAP.

Aquifer testing on monitoring well MW-3 found an average horizontal saturated hydraulic conductivity of  $4.8 \times 10^{-5}$  ft/s which yields a groundwater flow rate of approximately 19 ft/yr. Aquifer testing on monitoring well MW-5 found an average horizontal saturated hydraulic conductivity of  $2.1 \times 10^{-5}$  ft/s which yields a groundwater flow rate of approximately 49 ft/yr. Aquifer testing on monitoring well MW-6 found an average horizontal saturated hydraulic conductivity of  $5.6 \times 10^{-5}$  ft/s which yields a groundwater flow rate of approximately 127 ft/yr.

#### **4. GROUNDWATER ASSESSMENT RESULTS**

KEMRON's PCAR/CAP, included a recommendation for collection of additional site data. Specific activities, as further defined in the CTF Installation Work Plan, included the following: 1) the collection and analysis of sediment samples from the spill containment pond, 2) the removal and disposal of free-phase product in manhole FD-3, and 3) the collection and analyses of groundwater samples from the groundwater monitoring wells and underground drainage system for four consecutive quarters. The purpose of the quarterly groundwater monitoring was to develop a database of groundwater quality data. The installation work plan also included collection of additional soils data to further assess petroleum residues in site soils and spill containment pond sediments.

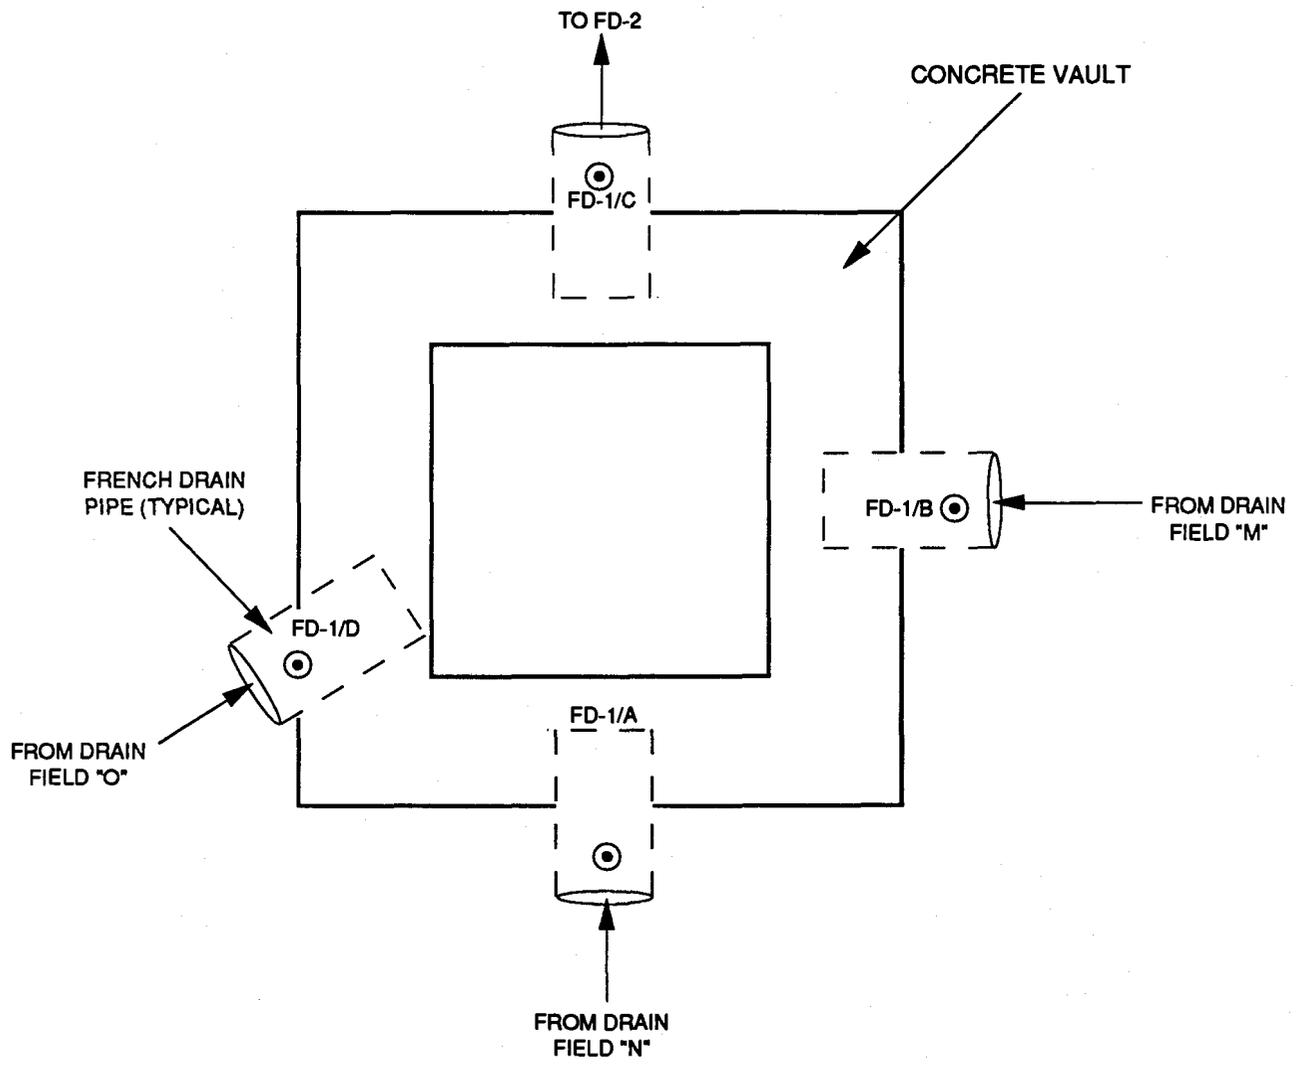

The 11 site monitoring wells were sampled and assayed quarterly for one year to monitor any increasing contaminant encroachment from off-site sources and to monitor for on-site fuel system leakage, should it occur. The french drain pipelines exposed within the three access manholes were sampled and assayed quarterly for a period of one year and to monitor any fuel system leakage should it occur. Additionally, quarterly monitoring of the french drain system was performed to help determine the source of petroleum film and dissolved petroleum contaminants in manhole FD-2 and measure the rate of free-phase petroleum accumulation which may occur in manhole FD-3.

Following collection and packaging, groundwater samples were transported to the laboratory and assayed for PAH, and BTEX using EPA Methods 8100, and 8020, respectively. Groundwater samples from well MW-5 were also assayed for RCRA metals. Groundwater samples collected from monitoring wells were also analyzed for temperature, pH, and specific conductivity in the field. Chain-of-custody was documented.

Eight groundwater samples were collected from the drain pipes in Manholes FD-1, FD-2, and FD-3 during each quarterly sampling event. These samples were designated "FD-1/A" through "FD-1/D", "FD-2/A" through "FD-2/C" and "FD-3." Groundwater sample locations are shown in Figures 4-1, 4-2 and 4-3. These samples were retrieved by inserting a decontaminated tygon hose several feet up each inlet and extracting the sample with a diaphragm pump or by dipping a decontaminated sampling device within the water to be sampled and transferring of the sample to labeled sample jars. Groundwater sample FD-3 was collected after the free-phase petroleum product was removed, as described above. With the exception of groundwater sample FD-3, petroleum odors were not detected in any groundwater samples.

**4.1 RESULTS OF BASELINE GROUNDWATER SAMPLING AND ANALYSIS.** The sampling and analysis conducted during the preliminary CAR is considered to be the baseline sampling and analysis event for the quarterly groundwater monitoring program. Results of this sampling and analysis are included in Chapter 3.

**4.2 RESULTS OF FIRST QUARTERLY GROUNDWATER SAMPLING AND ANALYSIS.** Between 16 and 17 March 1993, groundwater samples were collected from the eleven monitoring wells and designated as samples "MW-1" through "MW-11." In accordance with KEMRON quality assurance procedures, monitoring well MW-4 was resampled and designated as sample "MW-12," a blind duplicate.

Results of groundwater analyses show that, with the exception of the sample collected from MW-4, that neither BTEX nor PAH constituents are present above method detection limits in groundwater from monitoring wells or manholes. Results show the presence of total xylenes at 0.007 mg/L in the sample from MW-4. Analytical results from the first quarterly sampling event are summarized in Tables 4-1 and 4-2. These data may be compared with the baseline analytical data from the July 1990 sampling event presented in Tables 3-2 and 3-3.

Quantitative inspection of the chromatogram generated during analysis of sample FD-3 indicated the presence of petroleum constituents, but PAH constituents were below method detection limits of 0.1 and 0.5 mg/L. These elevated detection limits were due to matrix interferences experienced during the sample analysis.

In addition to analyses for PAH and BTEX, the groundwater sample collected from MW-5 was analyzed for RCRA total metals. Arsenic (0.086 mg/L), barium (0.13 mg/L), chromium (0.04 mg/L), and mercury (0.0003 mg/L) were present in the unfiltered sample at levels above method detection limits. Laboratory documentation for all groundwater analyses is presented in Appendix C.

#### **4.3 RESULTS OF SECOND QUARTERLY GROUNDWATER SAMPLING AND ANALYSIS.**

Groundwater samples were collected from each of the 11 monitoring wells on site and from locations in the french drain system as previously discussed. Results of second quarter sampling and analysis show that neither BTEX nor PAH constituents are present above method detection limits in groundwater from manholes or monitoring wells. Analytical results from the second quarterly sampling event are summarized in Tables 4-3 and 4-4.

Inspection of the chromatogram, illustrated in Figure 4-4, generated during analysis of the sample collected from FD-3 indicates that petroleum constituents are present in the groundwater, but PAH constituents are below method detection limits of 0.5 and 2.5 mg/L. These elevated detection limits are due to matrix interferences experienced during the sample analysis.

In addition to analyses for PAH and BTEX, the groundwater sample collected from MW-5 was analyzed for RCRA total metals. Arsenic (0.01 mg/L), barium (0.31 mg/L), chromium (0.08 mg/L), and lead (0.02 mg/L) were present in the unfiltered sample at levels above method detection limits. Laboratory documentation for all groundwater analyses is presented in Appendix D.

#### **4.4 RESULTS OF THIRD QUARTERLY GROUNDWATER SAMPLING AND ANALYSIS.**

Groundwater samples were collected from each of the 11 monitoring wells on site and from locations in the french drain system as previously discussed. QA/QC samples included a duplicate of FD-3, a trip blank (BTEX only) and an equipment rinse blank.

Results of groundwater analyses show that neither BTEX nor PAH constituents were present above method detection limits in groundwater from manholes or monitoring wells. Analytical results from the third quarterly sampling event are summarized in Tables 4-5 and 4-6.

Inspection of the chromatograms, illustrated in Figure 4-5, generated during analysis of the equipment blank and samples collected from french drain manholes, indicates that petroleum constituents were present, but Method 8100 target analytes are below detection limits. The equipment blank chromatogram illustrates a typical chromatogram for an uncontaminated sample; the spectrum has a

\*\*MW-12 is blind duplicate of FD-3.

\* High surrogate recovery and RIC suggest numerous co-eluting petroleum compounds

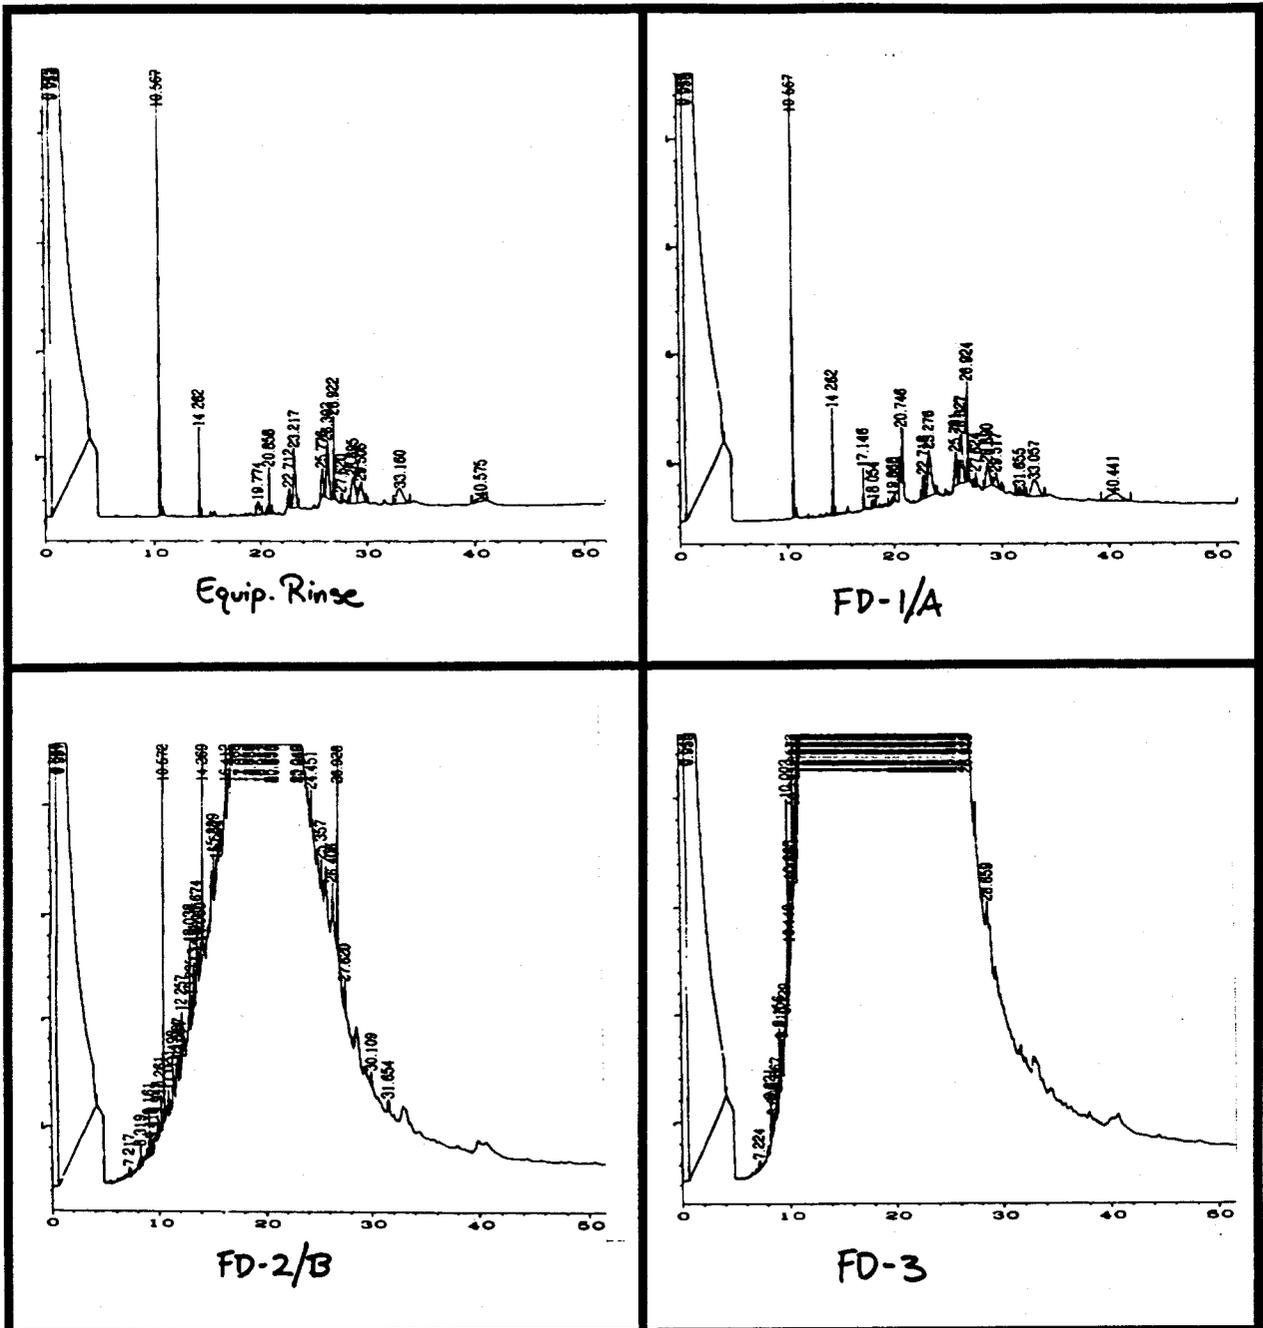

Figure 4-5. Representative reconstructed chromatograms from M8100 (PAH) analyses of equipment rinse sample and groundwater samples collected from french drain manholes. Vertical axes = FID intensity and horizontal axes = elution time in minutes.

relatively flat baseline with intermediate spikes corresponding to elution times for standard compounds. Method 8100 target compounds are not present in the spectrum.

In contrast, the chromatograms for samples collected from french drain manholes have elevated baselines, which form the large peaks, spanning from approximately 10-30 on the horizontal axis coordinates, in the chromatograms generated during analysis of sample FD-2/B and FD-3. The shape and location of these baseline "humps" are consistent with those expected for heavy fraction petroleum distillates. Although from these spectra it is apparent that a wide variety of petroleum compounds are present in the samples, Method 8100 PAH compounds are not present above method detection limits.

In addition to analyses for PAH and BTEX, the groundwater sample collected from MW-5 was analyzed for RCRA total metals. Arsenic (0.041 mg/L), barium (0.44 mg/L), chromium (0.09 mg/L), lead (0.03 mg/L), and mercury (0.0003 mg/L) were present in the unfiltered sample at levels above method detection limits. As illustrated in Table 4-5, where the metals results are compared to MCLs, lead is the only metal that exceeds the MCL. Laboratory documentation for all groundwater analyses is presented in Appendix E.

#### **4.5 RESULTS OF FOURTH QUARTERLY GROUNDWATER SAMPLING AND ANALYSIS.**

Groundwater samples were collected from each of the 11 monitoring wells on site and from locations in the french drain system as previously discussed. QA/QC samples included a duplicate of FD-3, a trip blank (BTEX only) and an equipment rinse blank.

Results of groundwater analyses show that neither BTEX nor PAH constituents were present above method detection limits in groundwater from manholes or monitoring wells. Analytical results from the fourth quarterly sampling event are summarized in Tables 4-7 and 4-8.

In an effort to more fully characterize the contaminants within samples exhibiting elevated baselines in historical PAH analyses, two groundwater samples, MW-2 and FD-3, were submitted to the laboratory for Semivolatiles Analyses by Method 8270. The analysis revealed the presence of non-target analytes. In an attempt to identify these, the spectral data were compared to the NBS library. Few matches were found at the required 85% matching criteria. However, the closest matching compounds are primarily hydrocarbons, as indicated in Table 4-9. Library search data, and an accompanying case narrative, are presented in Appendix F.

A number of observations concerning these data are noteworthy. First, the total concentration of all of these compounds is low, 1.052 mg/L, with the predominant constituent, dimethyl-heptadecane, a common hydrocarbon, present at less than 0.2 mg/L. Qualitatively, the compounds are predominantly hydrocarbons or substituted hydrocarbons (primarily methylated compounds). It must be recognized, however, that these compounds are listed here because they are not good identification matches and should be considered as "next best guesses." In addition, the list is biased, based only on the data contained in the computer database. Not every naturally-occurring compound has been identified, nor are all those identified in the database.

It is therefore not surprising that good matches could not be obtained for a number of the chromatogram peaks generated. Regardless, the actual compounds isolated should be close in chemical and physical properties (and therefore also in structure) to the compounds named. For example, a twenty-carbon hydrocarbon chain has ten different positions for a single methylation, each

Results presented in mg/L

4-17

producing a different, but similar derivative. As more substitutions are made, the resulting possibilities increase exponentially. All of the compounds listed are either hydrocarbons or close relatives, or degradation, reaction, or breakdown products of hydrocarbons. It is most unlikely then, that any exotic, potentially toxic compounds are present in the sample. The sample data are consistent with the presence of a refined petroleum product(s) containing high molecular weight hydrocarbons. Such products would be commonly used commercially as lubricating oils, greases, and heavy, partially refined fuel oils.

In addition to analyses for PAH and BTEX, the groundwater sample collected from MW-5 was analyzed for RCRA total metals. Arsenic (0.013 mg/L), barium (0.18 mg/L), chromium (0.06 mg/L), and lead (0.012 mg/L) were present in the unfiltered sample at levels above method detection limits. In Table 4-7, the metals results are compared to MCLs.

**4.6 GROUNDWATER FLOW DIRECTION.** To determine the groundwater flow direction, depth to groundwater measurements were taken in the wells prior to each sampling event. These measurements are summarized in Table 4-10. Using the depth to groundwater measurements, a potentiometric surface map was prepared for each sampling event. The resulting potentiometric surface maps are illustrated in Figures 4-6, 4-7, 4-8, 4-9, and 4-10. As shown in Figures, it is apparent that the dominant groundwater flow direction at the site is consistently toward the central french drain line and retention pond.

**4.7 FREE-PHASE PRODUCT REMOVAL.** On March 18, 1993, approximately 70 gallons of free-phase product were removed from manhole FD-3. Using a clean, 5-gallon container on a cord, the product was bailed from the open manhole and containerized in two 55-gallon drums. The free product appeared as a black, oily sludge containing grass and debris, which floated on top of the water within the manhole. The drums containing the product were then sealed and secured on site.

KEMRON is currently arranging for disposal of the petroleum product by a local waste oil reclamation firm.

## 5. SOIL ASSESSMENT RESULTS

Soil sampling was conducted as part of the PCAR to determine the site-wide distribution of petroleum residues in soils. These samples were collected as described in Chapter 3. Field observations during PCAR activities suggested that sediment in the spill containment pond was contaminated with petroleum residues. To provide additional information on the nature of the contamination in the pond, sediment samples were collected as part of the IWP.

### 5.1 SOIL SAMPLING RESULTS FROM PRELIMINARY CONTAMINATION ASSESSMENT.

Soil samples retrieved from drill rig-advanced boreholes showed little evidence of contamination. Total BTEX at a concentration of 0.062 mg/kg was found in borehole B-7 at a depth of 3.5 to 5.0 ft. below ground surface. Total PAH of 0.104 mg/kg was detected in the sample retrieved from 5.0 to 6.5 ft. below ground surface in borehole B-11. PAH and BTEX were not detected in the remaining soil samples. TPH was not detected in any soil samples.

5.2 RESULTS FROM SAMPLING AND ANALYSIS OF POND SEDIMENT. On 17 March 1993, eight sediment samples, designated as "Sed-1" through "Sed-8", were collected from the bottom of the spill containment pond at locations illustrated in Figure 5-1. A stainless steel hand auger was used to scoop the sediment sample from above the pond liner. The sediment samples were collected from the auger, containerized, labeled, and delivered to the laboratory. The samples were assayed for TPH, BTEX, and PAH, using EPA Methods 418.1, 8020, and 8100, respectively. In addition, the sediment samples were screened in the field for volatile organic compounds with a flame ionization detector (Foxboro OVA) to determine the extent of volatile organic vapors present within the sediments.

As summarized in Table 5-1, TPH was measured in sediment samples Sed-2 and Sed-7 at concentrations of 1,200 mg/kg and 610 mg/kg, respectively. The concentrations of TPH in the remaining sediment samples were below 260 mg/kg. With the exception of samples Sed-2 and Sed-9, laboratory analysis did not detect any BTEX constituents in the sediment samples. Xylene was measured at concentrations of 0.009 mg/kg and 0.007 mg/kg in samples Sed-2 and Sed-9, respectively. The only PAH compound present above method detection limits is fluorene, measured at 0.039 mg/kg in sample Sed-5. Laboratory documentation for sediment sample analytical results is presented in Appendix C.

### 5.3 RESULTS FROM CONFIRMATION SAMPLING AND ANALYSIS OF POND

SEDIMENT. As requested by Mr. Tim Mettlin of DHEC to Mr. John Sneed of Charleston Naval Base, dated 29 July 1993, confirmation analyses were performed. One sediment sample, collected from the location that yielded the highest TPH result from the previous sediment sampling event (Sed 2, 1200 mg/kg), was submitted for Gasoline Range Organics (GRO) and Diesel Range Organics (DRO) analysis by modified Method 8015 using extraction Methods 5030 for GRO and 3550 for DRO. These analyses were requested as confirmation analyses for the original TPH (by Method 418.1) analyses conducted to assess the pond sediment. It was noted by Mr. Mettlin that the 418.1 analysis is subject to potential false positives due to various interferences.

The sediment was resampled at the Sed-2 sampling location. Laboratory results show a GRO content of 0.18 mg/kg and DRO content of 22 mg/kg for the sample. Thus, the total TPH as measured by Method 8015 GRO/DRO is significantly less than the Method 418.1 result of 1,200 mg/kg from the same location.

## 6. SUMMARY AND CONCLUSIONS

### 6.1 NATURE AND EXTENT OF CONTAMINATION.

**6.1.1 Composition.** Tanks K, L, and P were historically used to store DFM. Seepage of fuel through the tank walls and into the pump rooms of these tanks has been observed since shortly after Navy Distillate replaced NSFO in the tanks in 1969. Laboratory analysis of free product samples retrieved from the french drain system in 1988 found a combination of DFM and NSFO. Leakage from one or all of these three tanks was thought to be the source of fuel oil discovered in the french drain system.

Results of the library search to identify non-target analytes in water samples show that sample FD-3 contains a number of compounds that are hydrocarbons or compounds resembling hydrocarbons. The sample data are consistent with the presence of a refined petroleum product(s) containing high molecular weight hydrocarbons. Such products would be commonly used commercially as lubricating oils, greases, and heavy, partially refined fuel oils such as NSFO and DFM.

**6.1.2 Sources.** The tracer survey, soil-gas survey, and soil sampling and analysis performed during this investigation detected only weak indications of petroleum leakage from the tanks or the associated piping. No free-phase petroleum or petroleum sheen was detected in the french drain manhole FD-1. A petroleum sheen was detected in french drain manhole FD-2. Free-phase product detected in french drain manhole FD-3 was removed during the first quarterly sampling event, and has yet to recharge.

The possible sources of the contamination present within manholes FD-2 and FD-3 include previous spills, illegal dumping into the drainage system, tank leaks, or leaking piping. The source of the petroleum sheen observed in manhole FD-2 is likely to be the fuel release on the eastern slope of tank P. In 1990, the petroleum sheen in manhole FD-2 was observed to be flowing from the french drain lateral from tank P. The free-phase petroleum observed in manhole FD-3 is possibly due to the above-mentioned tank P fuel release or may be due to illegal dumping into the drainage system. Speculation regarding the latter was noted during interviews with NSC personnel but appeared to be based only on the fact that fuel is observable in FD-3. The presence of grass and debris observed in manhole FD-3 and not observed in either of the other french drain manholes suggests dumping.

As discussed in Chapter 2, during a contamination assessment of the tank farm completed by ESE in 1986, nine soil samples were retrieved from borings installed around tanks K, L, and P. TPH and BTX assays performed on these samples failed to detect any evidence of petroleum contamination.

**6.1.3 Extent in Groundwater.** During the 1986 investigation, ESE collected groundwater samples from nine soil borings. Each water sample was examined for signs of petroleum contamination. The water sample retrieved from ESE borehole 3B, located northwest of tank K reportedly exhibited a petroleum sheen. None of the groundwater samples were reported to have exhibited a petroleum odor.

Analytical data from analysis of groundwater samples collected during the baseline sampling event and the quarterly sampling events shows that, for the most part, BTEX and PAH constituents are not present above method detection limits. TPH analyses from the PCAR activities show that measurable levels of TPH by Method 418.1 are not present in samples collected from groundwater monitoring wells. However, detectable levels were present in FD-3. This may be due to the presence of free-phase petroleum in the manhole during sampling. This petroleum was subsequently removed and has

not recharged, suggesting that there is no constant source of input, e.g., a free-phase petroleum plume on the water table. The only BTEX detections included detection of low level xylenes in MW-4 in the first quarter, but none were detected in the second, third, or fourth quarters.

As discussed in the second quarterly monitoring report, elevated detection limits from interferences on sample FD-3 prompted close examination of the Method 8100 chromatogram, which shows the presence of petroleum compounds in the sample. Inspection of the third quarter set of chromatograms from the Method 8100 analyses of samples collected from french drain manholes also show that petroleum constituents are present and the hydrocarbon spectra resemble heavy fraction petroleum hydrocarbons. This observation was substantiated by semivolatiles analyses of selected groundwater samples which qualitatively identified low level parts per billion, heavy petroleum distillate compounds.

**6.1.4 Extent in Soils.** Significant levels of BTEX, PAH, or TPH appear to be limited to sediments of the spill containment pond, where TPH values range up to 1,200 mg/kg.

**6.2 CONCLUSIONS.** The tracer survey, soil-gas survey, soil sample analyses, and groundwater sample analyses may be interpreted to indicate the following:

- no significant leaks from the tanks and pipelines are present at the site, although traces of petroleum contamination exist in soils and groundwater, with the exception of manhole FD-3 and the spill containment pond,
- low-level petroleum contamination is present in the groundwater near tank P,
- the petroleum film and minor contaminant detections are likely the result of the reported fuel overtopping, and
- petroleum contamination is confined to the french drain system and most notably manhole FD-3.

As presented in the PCAR/CAP, oil was observed on the walls of the pump rooms during the preliminary assessment activities, suggesting that sufficient porosity exists in the tank walls, where they are exposed in the pump rooms, to allow passage of petroleum into the pump rooms. Oil was not observed elsewhere adjacent to the tanks.

It appears that low-level petroleum and petroleum constituent contamination exists at the site due to historic releases. The most significant residues remaining are in the vicinity of tank P which was overtopped in approximately 1986. Substantial contamination is limited to manhole FD-3 and in sediments of the spill containment pond.

**6.3 RECOMMENDATIONS.** Because the storage tanks are no longer in use at the CTF and baseline and quarterly groundwater monitoring events have documented the presence of such small quantities of petroleum residues in groundwater, a "no further action" status is recommended with respect to groundwater at the site.

Similarly, substantial quantities of petroleum residues are present in only limited areas of the site, namely, in pond sediments. Thus, a "no further action" status is recommended for petroleum residues in site soils at this time. It is possible that some limited areas of contamination, primarily in the vicinity of the pump rooms, may be found during closure of the storage tanks, which will be

conducted as part of the base closure. Remediation of pond sediments, if required, may be conducted in conjunction with cleaning and permanent closure of the tanks.

## GLOSSARY

- BFB:** Bromofluorobenzene; the compound specified in EPA Method 624/8240 for which the mass spectrometer must meet performance criteria for VOA analysis.
- DFTPP:** Decafluorotriphenylphosphine; the compound specified in EPA Method 625/8270 for which the mass spectrometer must meet performance criteria for semivolatile compounds.
- EPA Method 624:** GC/MS method for determining volatile organic compounds in water using the purge and trap technique.
- EPA Method 625:** GC/MS method for determining semivolatile organic compounds in water using liquid/liquid extraction.
- EPA Method 8240:** GC/MS Method for determining volatile organic compounds in a variety of water and waste matrices using the purge and trap technique. Reference: SW-846.
- EPA Method 8270:** GC/MS Method for determining semivolatile organic compounds in a variety of water and waste matrices using liquid/liquid extraction and capillary column technique. Reference: SW-846.
- IS:** Internal Standard: compound used to determine response factors (RF) for individual analytes and subsequent quantitative analysis.
- RIC:** Reconstructed Ion Chromatograph; GC/MS chromatograph which plots total ion current versus scan number (time).
- SS:** Surrogate Standard; quality control compounds similar to the compounds of interest which are spiked into every sample matrix. The surrogate's recovery is determined using the same internal standard procedures and the analytes.
- VOA:** Volatile Organic Analysis; see EPA Method 624/8240.
- SV:** Semivolatile compounds; refers to the analytes determined by liquid/liquid extraction technique Method 625/8270.

MW-1	N3-09-187-10	09/10/93
EQUIP. RINSE	N3-09-187-11	09/10/93
TRIP BLANK	N3-09-187-12	09/10/93
MW-5	N3-09-187-13	09/10/93
SED 2	N3-09-187-14	09/10/93

Two samples (client ID MW-1 and Equip. Rinse) which required SW-846 Method 8100 analyses were extracted eight days from date of collection. All other samples were extracted and analyzed within the required holding times. Resampling and reanalyses of samples MW-1 and Equip. Rinse were performed in compliance. Results for the reanalysis data are traceable to work order # N3-10-008.

At your request the sample chromatograms were reviewed for a qualitative identification. It was observed that samples N3-09-187-1 through 5 contained hydrocarbon spectra resembling lube oil. Samples N3-09-187-6 through 11 contained amounts at or below the level of detection therefore no conclusion can be made for the identification. In addition, sample N3-09-187-04 was reported with a dilution factor 1. This was achieved only because the analytes detected by the first column analysis were not confirmed by the second column analysis as per SW-846 methodology. The interference produced by the lube oil carbon range typically requires a dilution; however in this case no. dilution was necessary.

**CASE NARRATIVE**  
**WORK ORDER NO. N3-12-230 and N3-12-231**

No difficulty was experienced in BETX5 or M8100 analysis of work order No. N3-12-230 which includes nine samples received on 12-10-93.

Similarly, no difficulty was experienced in BETX5, M8100 or M8270 analysis of workorder No. N3-12-231 which includes fourteen samples received on 12-10-93, with the exception of sample 05(FD-3). This sample exhibited an M8100 chromatogram typical of a hydrocarbon-type matrix necessitating analysis at a 10x dilution. The M8270 chromatogram exhibited a similar pattern. Mass spectral library search of the M8270 extract indicated that hydrocarbon-type compounds were present albeit at spectral purities too low for definitive identification. Please find enclosed M8100 and M8270 chromatograms and library search mass spectra for sample 05.
