PROFESSIONAL CERTIFICATION
Remedial Investigation Report
Site 1 (Disaster Recovery Area)
Naval Construction Battalion Center
Gulfport, Mississippi

This document that describes the Remedial Investigation for Site 1 (Disaster Recovery Area), Naval Construction Battalion Center, Gulfport, Mississippi, has been prepared under the direction of a Mississippi-registered professional engineer. The work and professional opinions rendered in this report were conducted or developed in accordance with commonly accepted procedures consistent with applicable standards of practice. If conditions are determined to exist that differ from those described, the undersigned professional engineer should be notified to evaluate the effects of additional information on the assessment described in this report. This report was developed specifically for the referenced site and should not be construed to apply to any other site.

Michael O. Jaynes, P.E.
Mississippi License Number PE 17816
Expires: December 31, 2010

EXECUTIVE SUMMARY

The primary objective of this Remedial Investigation (RI) was to provide data to evaluate current environmental conditions and guide the selection of a remedy that is protective of human health and the environment at Site 1 (Disaster Recovery Area), Naval Construction Battalion Center (NCBC) Gulfport, Mississippi. To achieve this primary objective, an RI including a geophysical survey and multi-phase sampling events from various media were conducted. Environmental samples were collected and analyzed during this RI to:

- Determine the extent of the waste disposal area.
- Identify the types of materials disposed of in the landfill and the potential chemicals of concern (COCs).
- Determine the extent and sources of mobile contaminants in soil and groundwater.
- Assess the potential impact to media including surface water and sediment and the surficial aquifer.

SITE BACKGROUND

Site 1 is an approximate 9 acres former landfill facility located north of 7th Street and east of Colby Avenue. The Site 1 landfill was in operation from 1942 to 1948. This area has most recently been used as a mock disaster recovery training village and as a training facility.

Site 1 was used as a landfill and was reportedly the primary area for waste disposal on base. Wastes were placed in unlined trenches at or near the groundwater table. The landfill, which operated from 1942 until 1948, received wastes generated at the base, mainly from public works shops and the supply department. Waste fuel, oil, solvents, paint, and paint thinners, reportedly in 55-gallon drums in many cases, were transported to the site and buried in the trenches (Envirodyne, 1985).

According to available information, waste was disposed of in trenches and then buried. Reportedly, the trenches were deeper than 8 feet and standing water was present in the open trenches. The waste disposal area at Site 1 was covered with soil when disposal activities ceased in 1948. Additional fill has been added over the years as parking lots and roads have been constructed over the surface.

PREVIOUS INVESTIGATIONS

The following previous environmental investigations have been conducted at Site 1:

1985 Initial Assessment Study (IAS) of NCBC Gulfport

The IAS identified and evaluated sites at NCBC Gulfport that were potential threats to human health and the environment. The IAS identified that waste disposal had occurred at Site 1 with the potential to impact human and ecological receptors. The IAS also discussed the excavation of the drums found in the southwestern corner of Site 1 and recommended a confirmation study.

1987 Confirmation Study

A Confirmation Study, which included a geophysical survey, surface water and sediment sampling, and monitoring well installation and sampling, was performed to confirm the data gathered from the IAS. Geophysical data suggested that native soil had been disturbed by excavation and disposal activities and identified several small magnetic anomalies. Four surface water samples were collected and low levels of oil and grease were detected. Composite sediment samples were collected from the Colby Avenue ditch, the southern Catfish Pond, and the northern Catfish Pond. Chromium was reported in several of the sediment samples. Three monitoring wells were installed and sampled with reported concentrations of volatile organic compounds (VOCs), base/neutral/acid (BNA) extractable organics, and cadmium less than laboratory detection limits. Chromium and lead were detected in each of the groundwater samples, at concentrations less than current Target Remediation Goals (TRGs).

1997 Field Verification Action

A Field Verification investigation was done at Site 1 to identify potential contamination. Direct-push technology (DPT) was used to collect subsurface soil samples at boring locations based on the geophysical survey completed in 1995. Thirty-three (33) soil borings were advanced at six of the anomalies. Dioxins and furans were reported in each of the soil samples collected for the Field Verification Action. Arsenic was detected at concentrations exceeding the unrestricted TRG in one or both sample intervals at 28 of the 33 soil boring locations.

1999 Groundwater Monitoring Report

Two downgradient monitoring wells were installed at Site 1 as part of the base-wide groundwater investigation. Low levels of dioxins and pesticides were detected in groundwater samples from Site 1.

FIELD INVESTIGATION

Site 1 RI field activities included the following:

- Geophysical investigation
- Soil-gas survey
- DPT soil and groundwater screening
- Surface water and sediment sampling
- Monitoring well installation and sampling
- Subsurface soil sampling
- Surface soil sampling

The screening criteria used to evaluate the nature and extent of contamination in environmental media at Site 1 included the Mississippi Department of Environmental Quality (MDEQ) Tier 1 TRGs and United States Environmental Protection Agency (USEPA) human health and ecological criteria. The potential impacts of contaminants identified at Site 1 to human and ecological receptors were evaluated in the human health risk assessment (HHRA) and the screening-level ecological risk assessment.

SITE HYDROLOGY

Surface water at Site 1 is found in ditches on the eastern and western sides of the site. The drainage ditch on the western side of the site receives surface water runoff from most of the disposal area identified at Site 1 and discharges to Canal No. 1 on the northern side of 8th Street. The canal on the eastern side of Site 1 receives limited runoff from the eastern part of Site 1 and flows to the north and discharges south of 28th Street at Outfall 3.

Groundwater elevations measured in September 2008 indicated groundwater flow in the shallow zone shows a north-south oriented divide near the middle of the site, with groundwater flow to the northwest to the west of the divide, and to the northeast to the east of the divide. Groundwater elevation data from the three deep zone wells was plotted and the groundwater flow direction is estimated to be to the northwest.

Groundwater flow velocity in the shallow surficial aquifer in the western part of Site 1 was 0.24 feet per day (ft/day). Groundwater flow velocity in the shallow surficial aquifer in the eastern part of Site 1 was 0.16 ft/day. The groundwater flow velocity in the deep surficial aquifer at Site 1 was 0.09 ft/day.

NATURE AND EXTENT OF CONTAMINATION

The release of contaminants at Site 1 appears to have resulted from routine aircraft maintenance operations. The time of disposal or accidental releases is unknown.

SOIL ASSESSMENT

The following chemicals were retained as surface soil chemicals of potential concern (COPCs) for the risk assessments:

- Direct Exposure (carcinogen) – dieldrin and arsenic
(non-carcinogen) – aluminum, antimony, cobalt, iron, and manganese
- Leaching to groundwater – tetrachloroethene, benzo(b)fluoranthene, Aroclor-1260, aldrin, alpha chlordane, benzene hexachloride (BHC) isomers, dieldrin, heptachlor epoxide, antimony, arsenic, chromium, cobalt, iron, lead, manganese, and selenium
- Ecological Receptors – aldrin, gamma BHC, dieldrin, endrin aldehyde, aluminum, antimony, copper, iron, lead, manganese, selenium, vanadium, and zinc

The following chemicals were retained as subsurface soil COPCs for the HHRA:

- Direct Exposure (carcinogen) – Aroclor-1242 and arsenic
(non-carcinogen) – aluminum
- Leaching to groundwater – alpha chlordane, Aroclor-1242, beta BHC, delta BHC, dieldrin, heptachlor epoxide, arsenic, chromium, and iron

GROUNDWATER ASSESSMENT

Groundwater characterization samples collected at Site 1 were analyzed for Target Compound List (TCL), Target Analyte List (TAL), and Appendix IX analytes. Groundwater delineation samples were collected using DPT and analyzed for selected VOCs.

The following chemicals were retained as groundwater COPCs for the HHRA:

- Direct Exposure (carcinogen) – tetrachloroethene, trichloroethene, naphthalene, and arsenic (non-carcinogen) – iron, manganese, and thallium
- Volatilization from groundwater – tetrachloroethene and trichloroethene

The interaction between the layers of sandy and clayey silt and the contaminants at the site appears to have created a vertical barrier to migration. Although not a true aquaclude, these lower permeability layers restrict the movement of contaminants such that the containment strategy of a soil cover should be effective in reducing future migration of contaminants and will be evaluated in the Feasibility Study (FS).

SURFACE WATER AND SEDIMENT ASSESSMENT

The concentrations of organic compounds [VOCs, semivolatile organic compounds (SVOCs), pesticides, polynuclear aromatic hydrocarbons (PCBs), and herbicides] reported in the surface water samples collected at Site 1 were less than the human health screening criteria; therefore, none of the organic compounds were retained as COPCs for the HHRA.

Arsenic was detected in one surface water sample at a concentration greater than the regional screening level (RSL) tap water criteria and is retained as a COPC in the HHRA.

Aluminum, iron, and lead were reported in Site 1 surface water samples at concentrations greater than the ecological screening values (ESVs) and are retained as ecological COPCs.

The following chemicals were retained as sediment COPCs for the risk assessments:

- Direct Exposure (carcinogen) – benzo(a)pyrene, benzo(b)fluoranthene, and arsenic (non-carcinogen) – aluminum, iron, and manganese
- Ecological Receptors – chrysene, fluoranthene, phenanthrene, pyrene, bis(2-ethylhexyl)phthalate, and chlordane

These results suggest that the contaminant levels reported in Site 1 surface water and sediment samples reflect base-wide conditions and do not result from releases from the landfill at Site 1.

MEDIA TO AIR MIGRATION PATHWAY

USEPA groundwater volatilization criteria (GVCs) have been established for many of the VOCs detected in groundwater at Site 1. Tetrachloroethene and trichloroethene were detected in one or more groundwater samples at concentrations greater than the default criteria, indicating the potential for migration and accumulation of vapors from the groundwater into the atmosphere.

HUMAN HEALTH RISK ASSESSMENT

Estimated risks for construction/excavation workers and adult trespassers were less than or equal to USEPA and MDEQ risk management benchmarks. The risk evaluation indicated that risk estimates for the site maintenance worker and adolescent trespasser were marginally greater than the MDEQ benchmark. The total ILCR for the site industrial worker exceeds the MDEQ cancer benchmark, the risk estimate is within one order of magnitude of the MDEQ benchmark and is primarily due to PCBs and dieldrin in soil contamination hot spots.

The risk evaluation also indicated that potential adverse health effects may be associated with the hypothetical future residential use of groundwater. The maximum detected concentration of tetrachloroethene in groundwater exceeded the Oak Ridge National Laboratory (ORNL) RSL for tap water, and the maximum concentration of arsenic in groundwater exceeded both the ORNL tap water RSL and the MDEQ groundwater TRG. The residential groundwater use scenario is evaluated to be conservative. The groundwater at Site 1 is not currently used as a source of drinking water and there are no plans to develop this resource in the future.

Residential cancer risk estimates slightly exceeded the MDEQ benchmark for soils (for both adult and child residents) due to dieldrin, arsenic, and PCBs. However, arsenic is within published background levels for soil. Sediment also exceeded the MDEQ cancer benchmark for the child resident only due to arsenic. Residential risks estimated for surface water did not exceed USEPA and MDEQ risk management benchmarks.

ECOLOGICAL RISK ASSESSMENT

Analytical data from surface soil samples collected at the site, and sediment and surface water samples collected from ditches on the eastern and western edges of the site, were evaluated in the ecological risk assessment.

VOCs and SVOCs in surface soil do not pose risks to ecological receptors. Several organochlorine insecticides were detected in surface soil samples. Concentrations tended to be low, and impacts to ecological receptors from these compounds are not expected. Concentrations of metals tended to be low and pose negligible potential risks to soil invertebrates and plants.

A low level of potential risk from exposure of benthic invertebrates to toluene may be present, but overall risk to benthic invertebrates from exposure to VOCs is considered negligible. Likewise, the low levels of VOCs detected in surface water do not appear to represent a potential risk to aquatic organisms. Concentrations of most metals tended to be low and pose negligible potential risks to aquatic and benthic organisms. Iron concentrations in surface water indicate potential risk to aquatic organisms.

Maximum exposure food chain HQs exceeded 1.0 for arsenic, lead, and zinc. In the average concentration scenario, all food chain HQs were less than 1.0; therefore, site-related impacts to receptors from COPCs in surface water and sediment are not expected.

CONCLUSIONS

Based on the results of the RI, an FS using Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) guidelines is recommended for Site 1. As discussed throughout this report, Site 1 meets the requirements of the presumptive remedy framework for municipal and military landfills. Therefore, the primary remedial strategy for Site 1 will be containment of the disposal area with a soil cap meeting state and USEPA requirements to prevent exposure to site soil.

The containment strategy should focus on three areas: (1) soil cover to prevent direct exposure to landfill materials; (2) elimination of the potential for mechanical disturbance of the cover during site operations; and (3) minimization of erosion of surface soil.

Based on the locations and types of chemicals detected during this investigation, interim removal or time-critical actions will not be required. After the above actions are taken, there will be a low likelihood for the migration of contaminated media, and the local population will not be exposed to contaminants in subsurface soil and groundwater at the site if current base operations and restrictions are maintained.

The FS will incorporate the presumptive remedy strategy including the soil cover to prevent recontamination in the future. The current soil cover is not likely to be adequate for permanent site closure under either MDEQ or USEPA regulations. Long-term monitoring and maintenance of the soil cover will be required.

1.0 INTRODUCTION

Tetra Tech NUS, Inc. (TtNUS) under contract to the United States Department of the Navy, Naval Facilities Engineering Command Southeast (NAVFAC SE), has prepared this Remedial Investigation (RI) Report for Site 1, Naval Construction Battalion Center (NCBC) Gulfport, located in Gulfport, Mississippi, under the Comprehensive Long-term Environmental Action Navy (CLEAN) IV Contract No. N62467-04-D-0055, Contract Task Order (CTO) 0065. Site 1, Disaster Recovery Disposal Area, is a former landfill located in the northwestern part of NCBC Gulfport.

1.1 PURPOSE OF REPORT

A broad framework for the RI and selection of the remedy process has been created through the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) by the United States Environmental Protection Agency (USEPA). The RI process (USEPA, 1991a) details the methodology that the Superfund program has established for characterizing the nature and extent of risks posed by uncontrolled hazardous waste sites and for evaluating potential remedial options.

The overall objectives of the RI process are:

- To adequately characterize the nature and extent of contamination at the site.
- To define the site dynamics, including contaminant migration pathways, transportation mechanisms, and potential receptors.
- To determine the site risks to human and ecological receptors.

USEPA has established the presumptive remedy framework for achieving each of these objectives while at the same time streamlining both the RI and remedy selection processes. Achieving these objectives will provide the basis for a remedy selection that is protective of human health and the environment. The proportion, distribution, and nature of the wastes present at Site 1 fit the parameters for the application of a containment presumptive remedy. Those characteristics are:

- Risks are low-level except for hotspots.
- Waste types are generally household, commercial, nonhazardous sludge, and industrial solid wastes.

- Lesser quantities of hazardous wastes are present as compared to municipal-type wastes.
- Low-hazard military-specific wastes may be present (low-level radioactive materials, decontamination kits, munitions hardware).

High hazard military wastes would preclude the use of presumptive remedy. Those waste types would include munitions, chemical warfare agents, and high-level radioactive wastes.

1.2 PRESUMPTIVE REMEDY PROCESS

Based on historical patterns of remedy selection for common categories of sites, including landfills, USEPA encourages the use of presumptive remedies (USEPA, 1993f) to increase consistency in remedy selection and to streamline the remedial action process. Prior to preparation of the Site 1 RI Work Plan, it was determined that a presumptive remedy for Site 1 was the best course of action based on the characteristics of the materials in the landfill and low concentrations of contaminants in the surficial aquifer (HLA, 1999). Based on USEPA guidance, a containment remedy involving a soil cover was incorporated into the site strategy to be consistent with USEPA guidance including Presumptive Remedy for Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Municipal Landfills (USEPA, 1993f), amended by the Application of the CERCLA Municipal Landfill Presumptive Remedy to Military Landfills (USEPA, 1996c), and MDEQ policy requiring a soil cover (containment) for this category of landfill as outlined in Mississippi Commission on Environmental Quality (MCEQ) Solid Waste Management Regulations (MCEQ, 2005).

1.3 INVESTIGATION USING PRESUMPTIVE REMEDY STRATEGY

The presumptive remedy process for landfills includes a streamlined approach to site characterization based on the remedial actions most likely to be selected. Site characterization for municipal landfills is expedited by focusing primarily on the information needed to sufficiently assess and address risks posed by the site. Therefore, there is less emphasis on extensively characterizing the soil and groundwater within the landfill disposal area and more of a focus on collecting pertinent data that satisfy the application of a containment presumptive remedy.

1.3.1 Landfill Contents

A complete characterization of the landfill's contents is generally not necessary because the landfill contents will be contained. However, certain landfill properties, such as vertical and lateral extent of the disposal area, age of the landfill, and disposal patterns, can influence the cover type.

1.3.2 Groundwater/Leachate Contamination

The characterization of site geology and hydrology will affect decisions on capping options as well as the monitoring and potential treatment of groundwater. Precipitation, groundwater-to-surface water recharge rates, and water table fluctuations can influence groundwater contamination plumes and leachate quantity. This characterization also includes assessing the impact to other potential receiving media such as the surface water and sediment and the surficial aquifer.

1.3.3 Hot Spots

Hot spots consist of highly toxic and/or highly mobile material and present a potential principal threat to human health or the environment. The presumptive remedy encourages the treatment of hot spots when this remediation would significantly reduce the risk posed by the overall site.

1.3.4 Baseline Risk Assessment

A baseline risk assessment was conducted to determine whether Site 1 poses risks to human health and the environment and to demonstrate that the containment presumptive remedy will address pathways and COCs.

This streamlined investigation framework is one area where the presumptive remedy methodology differs from the traditional RI approach. The Site 1 RI included sampling in and around the landfill disposal area to determine if the landfill contents meet the municipal landfill-type waste definition in Application of the CERCLA Municipal Landfill Presumptive Remedy to Military Landfills (USEPA, 1996c).

1.4 SITE BACKGROUND

NCBC Gulfport is located in the western part of Gulfport, Mississippi, in the southeastern part of Harrison County, about 2 miles north of the Gulf of Mexico (Figure 1-1). The property for the installation was acquired in April 1942 and occupies approximately 1,100 acres. NCBC Gulfport has an average elevation of 30 feet above sea level. Nine sites at NCBC Gulfport, including Site 1, were identified in the Initial Assessment Study (IAS) as potential threats to human health or the environment (Envirodyne, 1985).

The primary mission of NCBC Gulfport is to support military readiness for four battalions of the Naval Construction Force (NCF) and the storage and maintenance of pre-positioned War Reserve Material Stock. The NCF support consists of mobilization and logistics support for both homeport services and deployed support. Approximately 5,000 military and 1,600 civilian personnel are assigned to, or employed by, the base.

1.4.1 Site Description

Site 1 is a former landfill facility (in operation from 1942 to 1948) encompassing approximately 9 acres, although the areal extent of the waste disposal is smaller. The site is located north of 7th Street and east of Colby Avenue (Figure 1-2). This area has most recently been used as a mock disaster recovery training village and as a training facility.

Waste was disposed of in trenches and then buried. Reportedly, the trenches were deeper than 8 feet and standing water was present in the open trenches.

The waste disposal area at Site 1 was covered with soil when disposal activities ceased in 1948. Additional fill has been added over the years as parking lots and roads have been constructed over the surface. Buildings at Site 1 are intermittently occupied, and it is unknown if any of the buildings were constructed on top of the disposal trenches. The recapitalization plan for NCBC Gulfport will significantly alter the location and number of buildings at and near Site 1 through 2009.

Surface water is conveyed to ditches along the eastern and western boundaries of the site. Groundwater flow in and around Site 1 is to the northwest. There are no reports of the disposal of ordnance, radiological material, or biological/chemical warfare agents at Site 1.

1.4.2 Site History

Site 1 was used from 1942 to 1948 as a landfill and was reportedly the primary area for chemical waste disposal on base. Wastes were placed in unlined trenches at or near the groundwater table. The landfill received chemical wastes generated at NCBC Gulfport, mainly from public works shops and the supply department. Waste fuel, oil, solvents, paint, and paint thinners, many reportedly in 55-gallon drums, were transported to the site and buried in the trenches (Envirodyne, 1985).

In 1984, during water line repairs in the southwestern corner of Site 1, four or five rusted 55-gallon drums were excavated. The drums were highly deteriorated, and the drum contents were described as tar-like with a strong odor similar to burnt plastic. The drums were transported to the concrete foundation of former Building 271 (later designated Site 9) for storage pending analytical results of the drum contents. The sample of drum contents was analyzed for hazardous waste characterization for metals and volatiles and for flammability, reactivity, and corrosiveness. The material sampled from the drums contained xylene, toluene, 1,2-dichloroethane, and low levels of arsenic and lead.

1.4.3 Previous Investigations

The following previous environmental investigations have been conducted at Site 1:

1985 Initial Assessment Study of NCBC Gulfport

The IAS, carried out by Envirodyne (1985) under the Naval Energy and Environmental Support Activity (NEESA), identified and evaluated sites at NCBC Gulfport that were potential threats to human health and the environment. The IAS included the following:

- Records search
- On-site survey
- Site ranking
- Outline for a subsequent Confirmation Study

The IAS identified that waste disposal had occurred at Site 1 with the potential to impact human and ecological receptors. The IAS also discussed the excavation of the drums found in the southwestern corner of Site 1 and recommended a confirmation study.

1987 Confirmation Study

The Confirmation Study was conducted by HLA (1987) and included a geophysical survey, surface water and sediment sampling, and monitoring well installation and sampling.

The geophysical survey collected very low frequency electromagnetic data which detect variations in soil conductivity, and magnetometer data which measure variations in the total magnetic field associated with magnetic objects. The grid spacing for this survey was 50 feet. More than half of Site 1 exhibited very low frequency values greater than the background value, suggesting that native soil had been disturbed by excavation and disposal activities. The magnetometer data identified several small magnetic anomalies.

Four surface water samples were collected during the Confirmation Study from the ditch on the western side of Site 1 adjacent to Colby Avenue, from the southernmost Catfish Pond adjacent to the northern edge of Site 1, from the northernmost Catfish Pond, and from an isolated ditch located near the center of Site 1 in the disaster recovery training area. The surface water samples were analyzed for selected metals (cadmium, chromium, and lead), oil and grease, total organic carbon, total organic halides, and chemical oxygen demand. Concentrations of metals in the surface water samples were less than laboratory detection limits. Low levels of oil and grease were detected in the surface water samples.

Composite sediment samples were collected from the Colby Avenue ditch, the southern Catfish Pond, and the northern Catfish Pond, and a sediment grab sample co-located with the surface water sample was collected in the ditch near the center of Site 1. The sediment samples were analyzed for selected metals, oil and grease, total organic carbons, total organic halides, and chemical oxygen demand. Chromium was reported in several of the sediment samples. Other metal concentrations were less than laboratory detection limits.

Three monitoring wells were installed and sampled as part of the Confirmation Study. Monitoring well GPT-1-1 was installed in the southwestern part of the site, and GPT-1-2 was installed near the southeastern part of the site. One monitoring well (GPT-01-03) was installed at the northern edge of the site, adjacent to the Catfish Pond. The monitoring wells were screened from a depth of 3 feet to total depths between 25 to 30 feet. The groundwater samples were analyzed for volatile organic compounds (VOCs), base/neutral/acid (BNA) extractable organics, and selected metals (cadmium, chromium, and lead). Reported concentrations of VOCs, BNAs, and cadmium were less than laboratory detection limits. Chromium and lead were detected in each of the groundwater samples, at concentrations less than current Target Remediation Goals (TRG).

1997 Field Verification Action

Morrison Knudsen Corporation conducted the Field Verification Action at Site 1 to determine whether hazardous constituents, particularly dioxin-related compounds, were present in subsurface soil. Direct-push technology (DPT) was used to collect subsurface soil samples at boring locations based on the geophysical survey completed in 1995. Thirty-three (33) soil borings were advanced at six of the anomalies identified as large or major metallic targets (Figure 1-3). Soil samples were collected at each boring location from depths between 3 and 6 feet and 9 to 13 feet and submitted for laboratory analysis. The soil samples were analyzed for VOCs, semivolatile organic compounds (SVOCs), Resource Conservation and Recovery Act (RCRA) metals, dioxins and furans, pesticides, polychlorinated biphenyls (PCBs), and herbicides.

Dioxins and furans were reported in each of the soil samples collected for the Field Verification Action. At one sample location A4-1, the toxic equivalency quotient (TEQ) in the 3 to 5 foot sample [27.6 nanograms per kilogram (ng/kg)] was greater than the unrestricted TRG (4.26 ng/kg), but less than the restricted TRG (38.2 ng/kg) (Figure 1-4).

Arsenic was detected at concentrations exceeding the unrestricted TRG in one or both sample intervals at 28 of the 33 soil boring locations (Figure 1-4). The arsenic concentration in the sample collected from 2 to 4 feet at A3-9 was 455 milligrams per kilogram (mg/kg), which is greater than the restricted TRG of 3.82 mg/kg.

Concentrations of other analytes detected in the soil samples were less than the TRGs. Positive detections from the verification study are provided in Table 1-1 at the end of this section.

1999 Groundwater Monitoring Report

As part of the base-wide groundwater investigation, which focused on dioxins, two downgradient monitoring wells (GPT-01-04 and GPT-01-05) were installed at Site 1 (Figure 1-3). Low levels of dioxins (predominantly the octo-chlorinated congener) and pesticides were detected in groundwater samples from Site 1. All results were less than Maximum Contaminant Levels (MCLs). The initial characterization of the surficial aquifer at NCBC was refined during this investigation. The relationship between surface water and groundwater at the base was also evaluated, and significant interaction between surface water and groundwater was reported.

1.4.4 Presumptive Remedy Investigation Objectives

As discussed in Section 1.3, to achieve the objectives of the presumptive remedy RI, the following information was needed:

- Verify the extent of the waste disposal area
- Identify the types of materials disposed of in the landfill
- Determine the extent and sources of mobile contaminants
- Assess potential impact to receptors
- Evaluate risks posed to human health and local ecology

To collect this information, the RI conducted at Site 1 included the following activities, as described in Section 2.0:

- Geophysical survey
- Passive soil-gas survey for VOCs
- Surface water and sediment sampling
- DPT groundwater screening
- Monitoring well installation
- Groundwater sampling
- Surface and subsurface soil sampling
- Aquifer characterization

1.5 PRELIMINARY RESPONSE ACTION OBJECTIVES

As a first step in evaluating the suitability of containment alternatives, response action objectives were developed. The presumptive remedy response action objectives focus on waste isolation and containment and are as follows:

- Preventing direct contact with landfill contents
- Minimizing infiltration and containment of leaching to groundwater
- Controlling surface water runoff and erosion
- Controlling landfill gas (if necessary)

1.6 REPORT ORGANIZATION

This report consolidates the results of the previous sampling activities summarized above and the RI and includes the following eight sections:

- 1.0 Introduction
- 2.0 Study Area Investigation
- 3.0 Physical Characteristics of the Study Area
- 4.0 Nature and Extent of Contamination
- 5.0 Contaminant Fate and Transport
- 6.0 Human Health Risk Assessment
- 7.0 Screening Level Ecological Risk Assessment
- 8.0 Summary and Conclusions

The following appendices are included with this report:

- Appendix A – Geophysical Survey Report
- Appendix B – Soil Gas Survey Report
- Appendix C – Field Data
- Appendix D – Validated Laboratory Data
- Appendix E – Human Health Risk Assessment Supporting Data
- Appendix F – Screening Level Ecological Risk Assessment Food-Chain Mode
- Appendix G – Previous Investigations

2.0 STUDY AREA INVESTIGATION

This section provides the details of RI activities conducted at Site 1. Data were collected during this RI to:

- Determine the extent of the waste disposal area.
- Identify the types of materials disposed of in the landfill and the chemicals of potential concern (COPCs).
- Determine the extent and sources of mobile contaminants in soil and groundwater.
- Assess the potential impact to media including surface water and sediment and the surficial aquifer.

Site 1 RI field activities included the following:

- Geophysical investigation
- Passive soil-gas survey
- Surface soil sampling
- Subsurface soil sampling
- DPT groundwater screening
- Monitoring well installation and sampling
- Surface water and sediment sampling
- Aquifer characterization

2.1 GEOPHYSICAL INVESTIGATION

An important element of the containment presumptive remedy for landfills is to adequately determine the extent of the disposal area. A geophysical survey was conducted at Site 1 to locate individual disposal cells and to delineate the extent of the landfill. Data from the geophysical survey were used to guide later phases of the investigation.

Magnetic and terrain conductivity (EM-31) geophysical surveys were conducted at the suspected disposal areas at Site 1 (Figure 2-1). These surveys were based on a 10-foot line spacing grid.

On the golf course area north of Site 1 (former location of catfish ponds) a meandering path EM-31 survey was conducted (Figure 2-1). This survey was used to rapidly screen the Catfish Pond area for unreported disposal cells. The report for the geophysical investigation is included in Appendix A.

2.2 SOIL AND VADOSE ZONE INVESTIGATIONS

The soil and vadose zone investigations, which included a passive soil-gas survey and surface and subsurface soil sampling for chemical analysis, were implemented to refine the delineation of the waste disposal area and confirm that landfill contents meet the municipal-type waste definition.

In addition, investigations were conducted to screen for landfill gas generation and to determine the grain size of the fill material used in the existing soil cover.

2.2.1 Passive Soil-Gas Survey

The passive soil gas survey was a qualitative study of volatile contaminants in shallow subsurface soil and groundwater. Passive soil-gas samplers were used to collect media-composite samples from the vadose zone and shallow surficial aquifer. The 32 samplers were installed to investigate anomalies identified in the geophysical survey where waste disposal was suspected to have occurred. One, two, or three soil gas samplers were installed at the individual anomalies, based on the extent of the anomaly (Figure 2-2). Eight samplers were lost or destroyed before recovery. The report from the soil gas survey is included in Appendix B.

This assessment was not a complete characterization of vadose zone chemistry at Site 1; rather the results provided an efficient means of determining hot spots in the study area and supported the subsequent investigative phases of the RI.

2.2.2 Surface Soil Investigation

The surface soil investigation was conducted to determine if the existing surface soil at the site can be integrated into a final cover. Twenty-one (21) sample locations were selected from the landfill disposal area for chemical analysis (Figure 2-3). Field sampling records are included in Appendix C. One surface soil sample was collected from 0 to 1 foot at 19 locations and 0 to 2 feet at 2 locations.

The surface soil samples were analyzed for target compound list (TCL) VOCs, TCL SVOCs, TCL pesticides and PCBs, Appendix IX chlorinated herbicides, and target analyte list (TAL) inorganics (see Table 2-1). The results of the surface soil investigation are presented in Section 4.2.2. Validated data are included in Appendix D.

2.2.3 Subsurface Soil Investigation

Because extensive subsurface soil sampling was conducted for the 1997 Field Verification Action (discussed in Section 1.4.3), subsurface soil sampling for the RI focused on sampling for VOCs, which

may have migrated from the waste disposal areas since the previous sampling event, and on subsurface soils adjacent to the canal on the east side of Site 1, which potentially could be disturbed during planned construction activities.

2.2.3.1 DPT Subsurface Soil Samples

Because extensive subsurface soil sampling was conducted at Site 1 for the Field Verification Study, subsurface soil sampling for the RI concentrated on evaluating the current concentrations of VOCs, the most mobile contaminants suspected to have been disposed of during landfill operations. One subsurface soil sample was collected from each of 10 drilling locations (see Figure 2-3). The drilling locations were selected to coincide with the margins of the waste area and provide a cross-sectional characterization of the shallow subsurface across the site. These samples were submitted for quick-turnaround analysis for TCL VOCs. Soil boring logs are included in Appendix C. Validated data are included in Appendix D.

2.2.3.2 Canal Bank Samples

Seven additional soil samples were collected adjacent to the canal on the east side of Site 1. These sample locations were outside of the area previously investigated. Three of the samples were analyzed for a full suite of analyses, TCL VOCs, TCL SVOCs, TCL pesticides and PCBs, Appendix IX chlorinated herbicides, and TAL inorganics (see Table 2-1). The other four samples were analyzed only for PCBs. Validated data are included in Appendix D.

2.2.4 Landfill Gas Screening

The landfill gas screening was conducted to detect generation of landfill gases at Site 1. The evaluation included the collection and field analysis of vadose zone gas samples from four locations at Site 1 (shown on Figure 2-4). Locations were evenly spaced over the disposal area. At one location, 01LG05, groundwater was pulled into the sample train and readings were not taken.

The vadose zone sampling was conducted with an expendable probe system because of potential for the water table to be very close to the ground surface. The sampling probe tip was attached to a length of teflon tubing and was driven with a slide hammer to a depth of 1 foot below land surface (bls) and the surface annular space was sealed with clay. A GEM 2000 landfill gas monitor was attached to the tubing and was used to purge the system. The GEM 2000 was used to monitor concentrations of methane (% CH₄), oxygen (% O₂), and carbon dioxide (% CO₂). Readings were recorded at two time intervals (at 5 and 10 minutes elapsed time). At each sampling location, the readings showed that the vadose zone gas concentrations had stabilized (consistent reading maintained for 5 minutes). Then a Multi-Rae multi-gas

meter was attached to the tubing and readings were recorded for oxygen (%O₂), methane lower explosive limit (% LEL), VOCs [photoionization detector (PID) in parts per million (ppm)], carbon monoxide (ppm CO), and hydrogen sulfide (ppm H₂S).

2.2.5 Grain Size Sampling and Analysis

Surface soil samples were collected at five locations in the waste disposal area (Figure 2-4) to provide preliminary quantitative data on the material forming the existing soil cover. The five samples were analyzed for grain size distribution (ASTM D 422).

2.3 GROUNDWATER INVESTIGATIONS

Groundwater sampling during the RI included DPT groundwater screening and permanent monitoring well sampling. DPT groundwater sampling was conducted to support the soil-gas study, and monitoring well sampling was conducted to characterize site groundwater conditions. Figure 2-5 includes DPT sample locations, and Figure 2-6 includes monitoring well locations.

2.3.1 DPT Groundwater Screening

A DPT rig was mobilized to complete a groundwater investigation following an assessment of the soil-gas modules. A total of 29 groundwater samples from 29 locations were collected via temporary wells and analyzed for VOCs using Method 8260.

At each location, a 2-inch-diameter well screen was driven to a selected depth, based on site lithology, and then exposed to a discrete 4-foot interval of the water-bearing zone. Samples were collected at depths ranging from 6 feet to 45 feet. The results of the DPT groundwater screening are presented in Section 4.3.1.

2.3.2 Monitoring Well Installation and Sampling

A total of 22 permanent monitoring wells (GPT-01-06 through GPT-01-27) were installed at Site 1 during the RI at locations chosen based on the results of the DPT groundwater investigation (see Table 2-2). Wells were installed upgradient and downgradient of the landfill to evaluate potential migration of contamination, and well pairs and clusters were installed to evaluate vertical groundwater gradients. Wells were screened in the shallow and deep zones of the shallow surficial aquifer. Well locations are presented on Figure 2-6.

Monitoring well groundwater samples were analyzed for TCL VOCs, TCL SVOCs, TCL pesticides and PCBs, Appendix IX chlorinated herbicides, and TAL inorganics. Groundwater quality parameters

including pH, conductivity, temperature, dissolved oxygen, and turbidity were measured with field instruments at each monitoring well during sampling activities. The monitoring well groundwater results are presented in Section 4.3.2. Groundwater sample log sheets are included in Appendix C.

Monitoring wells were installed using DPT methods and were constructed of 1-inch-diameter, Schedule 40 polyvinyl chloride (PVC) flush-threaded casing with 5-foot (deep wells) or 10-foot (shallow and intermediate wells), 0.01-inch slotted, PVC, pre-packed screens. The shallow monitoring wells were installed to total depths averaging 14 feet. Four intermediate wells (GPT-01-07/GPT-01-10/GPT-01-12/GPT-01-14) were installed to total depths between 23 and 29 feet. Deep monitoring wells (GPT-01-6/GPT-01-9/GPT-01-11) were installed to total depths between 40 and 49 feet. A 2-foot-thick bentonite pellet seal was installed above the 20/40 sand filter pack. The remainder of the annulus of the borehole was grouted with cement/bentonite slurry. The monitoring wells were completed at ground surface with flush-mount vaults, as specified in the Southern Division Specifications for Monitoring Well Completion and Abandonment (NFESC, 1999). The horizontal location and top of casing elevation for each new monitoring well was surveyed by a Mississippi-licensed professional land surveyor. Monitoring well construction details are summarized in Table 2-2.

2.4 SURFACE WATER AND SEDIMENT INVESTIGATION

Surface water and sediment samples were collected during the RI from drainage ditches bordering the east and west sides of Site 1. The data collected were used to characterize the general aquatic environmental quality in these ditches. Five co-located surface water and sediment samples were collected (Figure 2-7). Three of the samples (01SW/SD0101, 01SW/SD0201, and 01SW/SD0301) were collected from or adjacent to the shallow, concrete-lined drainage ditch on the west side of Site 1, parallel to Colby Ave. At the time of sample collection, maintenance workers had cleaned the sediment from the ditch. Therefore, at locations 01SD0201 and 01SD0301, sediment was collected from the locations where shallow drainage swales from Site 1 intersected the concrete-lined ditch. The surface water samples were collected from within the ditch. The surface water and sediment samples collected at 01SW/SD0101 were collected from the mouth of a culvert, where the ditch had not been cleaned. Two surface water and sediment sample locations (01SW/SD0401 and 01SW/SD0501) were located in the larger drainage ditch on the east side of Site 1.

The surface water and sediment samples were analyzed for TCL VOCs, TCL SVOCs, TCL pesticides and PCBs, Appendix IX chlorinated herbicides, and TAL inorganics. Surface water and sediment results are presented in Section 4.4. Surface water and sediment sample log sheets are included in Appendix C.

2.5 AQUIFER CHARACTERIZATION

Static water level (SWL) measurement data were recorded from Site 1 monitoring wells in September of 2008. The monitoring well locations are shown on Figure 2-6. The SWL measurement data and top of casing elevations were used to determine groundwater elevations at site monitoring wells. The groundwater elevations were used to estimate flow direction and horizontal and vertical gradients at each site.

Hydraulic conductivity values were calculated from slug tests that were conducted in wells at Site 3, which is located approximately 750 feet to the northwest of Site 1 (Site 3 RI) and Site 4, which is located approximately 500 feet to the west of Site 1 (Site 4 RI). Because the hydrogeology of these sites is similar, additional slug tests were not conducted at Site 1.

3.0 PHYSICAL CHARACTERISTICS OF THE STUDY AREA

NCBC Gulfport is located in the western part of the City of Gulfport, Mississippi, in southeastern Harrison County, approximately 2 miles north of the Gulf of Mexico. NCBC Gulfport occupies approximately 1,100 acres and has an average elevation of approximately 30 feet above sea level.

3.1 SURFACE FEATURES

Site 1 is a former landfill facility encompassing approximately 9 acres, although the areal extent of the waste disposal is smaller (Figure 3-1). The site is bordered on the north by facilities of the Pine Bayou Golf Course. Planted pine trees are present across the site. The site topography is relatively flat, with elevations of approximately 20 to 24 feet above mean sea level.

3.2 METEOROLOGY

The Gulfport area has a mild climate with warm and humid summers [average temperature of 82 degrees Fahrenheit (°F)] and mild winters (average temperature of 52 °F). The mean annual precipitation is 63.5 inches, and individual storms are often intense and may produce large 24-hour precipitation totals. The Mississippi coast is subject to hurricanes between June 1 and November 30.

3.3 SURFACE WATER HYDROLOGY

NCBC Gulfport is located in the Gulf Coast Flatwoods Region, which extends along the southern coast of Harrison County. This area is typically drained by small streams flowing southeastward toward the coast. Topography in this area is a series of wet, poorly drained depressions between better drained areas of slightly higher elevation.

Surface water in the vicinity of NCBC Gulfport is abundant. Storm water runoff is collected in a series of ditches and canals and directed off base. Large precipitation events tend to produce small stream and ditch flooding due to relatively high stream flow velocities.

The drainage ditch on the western side of the site receives surface water runoff from most of the disposal area identified at Site 1 and discharges to Canal No. 1 on the northern side of 8th Street (Figure 3-1).

The canal on the eastern side of Site 1 receives limited runoff from the eastern part of Site 1 and flows to the north and discharges south of 28th Street at Outfall 3.

3.4 GEOLOGY

Data collected from soil borings advanced at Site 1 were used to evaluate the lithologic and stratigraphic conditions that may influence contaminant fate and transport at the site.

3.4.1 Site Stratigraphy

Surface and shallow subsurface soils in the Site 1 area are primarily gray and brown sand to sandy silt with varying amounts of gravel and minor clay horizons. Figure 3-2 shows the locations of soil borings used to develop the geologic cross section, Figure 3-3. The uppermost 2 feet in most areas is fill material. Below the fill material, typical lithologies are light brown and gray fine sands and silty fine sands. These strata are typical of Pleistocene and Recent age terrace and stream valley deposits. Some horizons contain stringers of fine, subrounded, quartz gravel or shell fragments to depths of up to 20 feet. The top of a gray silt unit with sand and clay is encountered at depths of approximately 20 to 30 feet bls, depending on site topography. This clay-rich layer is persistent across the site, with thicknesses ranging from 5 to 10 feet.

Below the gray clayey sand layer, gray silty sand, and sand lithologies are present at depths ranging from 35 to 50 feet. This sand unit is 5 to 10 feet thick over most of the site. At depths of approximately 40 to 48 feet, a much more plastic green-gray clayey silt layer was encountered. This layer is persistent across the site and, based on other sites investigated at NCBC Gulfport, ranges from 10 to 50 feet thick (HLA, 1999). This layer may represent an aquitard that separates the shallow surficial aquifer from deeper water-bearing units.

3.4.2 Regional Geology

NCBC Gulfport is located in the coastal plain of southern Mississippi, which is underlain by a series of estuarine or deltaic sediments that dip southwestward toward the delta of the Mississippi River (Shows, 1970). These sediments range in age from Miocene to Recent and are not readily separated into stratigraphic units. The uppermost beds are Pleistocene and Recent terrace and stream valley deposits. The uppermost stratigraphic unit in the coastal plain area is the Pamlico Sand. The Pamlico Sand formation is approximately 60 to 70 feet thick and is composed of fine silt, sands, and shale, or clay. The Pamlico Sand is underlain by the following formations:

- Citronelle Formation (youngest), approximately 100 feet thick.
- Graham Ferry Formation, alternating layers of sand, shale, and clay ranging from 125 to 250 feet thick.
- Upper and Lower Pascagoula Formations (oldest), alternating layers of sand, shale, and clay with shell and boulders approximately 1,100 feet thick.

3.5 SOILS

Surface and shallow subsurface soils identified from soil borings at Site 1 are primarily sand and silty sand with minor clay horizons. Native soils typically begin at depths of 1 to 2 feet, depending on topography.

The Soil Survey of Harrison County [United States Department of Agriculture (USDA), 1975] identifies the soil type in the developed areas of Site 1 where landfill operations occurred as Harleston fine sandy loam with 0 to 2 percent slopes, a moderately well-drained soil developed in loamy material and commonly found on uplands. This soil type is typically sandy loam and fine sandy loam and is strongly acid to very strongly acid. Permeability is moderate, available water capacity is medium, and runoff is slow.

3.6 HYDROGEOLOGY

Hydrogeologic data were collected to evaluate movement of groundwater in the shallow surficial aquifer at the site. The lithologies at Site 1 are consistent with the typical surficial aquifer of the Mississippi Coastal Plain, composed of undifferentiated alluvium and Pamlico Sand terrace deposits (Recent to Pleistocene in age). The Pamlico Sand formation is approximately 60 to 70 feet thick and is composed of fine sands and clay.

The monitoring wells installed for the RI are grouped into two zones, shallow and deep. The shallow wells include water table wells installed to depths of 13 to 14 feet and the wells installed to depths of approximately 25 to 30 feet bls, at the top of the gray silt unit. Deep wells were installed to depths of approximately 40 to 50 feet bls, at the top of the green silt unit and are screened in the sandy unit between the silt units.

Depth to groundwater and groundwater elevation data were used to determine the site-specific groundwater flow direction and water table gradient. Groundwater flow velocity at the site was estimated using hydraulic conductivity values determined for selected site monitoring wells and hydraulic gradient data.

3.6.1 Static Water Level and Groundwater Elevations

The depth to groundwater at NCBC Gulfport ranges from approximately 2 to 10 feet and is controlled primarily by surface topography. Water level measurement data were recorded from Site 1 monitoring wells in September 2008 (see Table 3-1).

Depth to water measurements in the shallow wells ranged from 0.57 to 6.86 feet bls. Depths to water are greater in the areas of higher elevation in the southern and eastern parts of the site and decrease with elevation approaching the ditch on the western boundary of the site.

Depth to water measurements in the deep wells ranged from 1.89 to 5.20 feet. Depth to water was greatest at GPT-01-09, located in the north central part of Site 1 and decreased to the west and east.

3.6.2 Groundwater Flow Direction

Groundwater elevations measured in September 2008 were plotted and contoured on maps for the shallow zone (Figure 3-4). Based on these contours, groundwater flow in the shallow zone shows a north-south oriented divide near the middle of the site, with groundwater flow to the northwest to the west of the divide, and to the northeast to the east of the divide.

Groundwater elevation data from the three deep zone wells was plotted and the groundwater flow direction is estimated to be to the northwest (Figure 3-5).

3.6.3 Horizontal Hydraulic Gradient

The average horizontal groundwater gradient across the site was calculated using the following equation and groundwater elevations measured in site monitoring wells and the estimated groundwater flow direction:

$$I \equiv \frac{h_1 - h_2}{d}$$

where:

I = hydraulic gradient

h_1 = groundwater elevation at point 1, the highest value

h_2 = groundwater elevation at point 2, the lowest value

d = horizontal distance between points 1 and 2 parallel to direction of groundwater flow

The highest and lowest groundwater elevations measured in monitoring wells from each aquifer zone (shallow and deep) were used to determine the difference in groundwater elevation for that zone across the site (Table 3-2). Because there is a groundwater divide in the shallow zone, gradients were calculated for the western and eastern sides of the site. The horizontal distance between the high and low groundwater elevation points in each zone was measured parallel to the estimated groundwater flow direction.

The average gradient in the shallow wells west of the groundwater divide was 0.003 feet per foot (ft/ft). The average gradient in the shallow wells east of the groundwater divide was 0.002 ft/ft. The gradient in the deep wells was 0.008 ft/ft.

3.6.4 Vertical Hydraulic Gradient

The vertical groundwater gradient was estimated from groundwater elevations measured in shallow and deep monitoring well pairs installed at the site. The vertical gradient is determined from the difference in groundwater elevations in adjacent shallow and deep monitoring wells and the vertical separation of the screened intervals of the monitoring wells. The vertical separation of each well cluster is the difference in depth below grade of the middle of the shallow well screened interval and the middle of the deep well screened interval. If the groundwater elevation in the shallow well in a cluster is higher than the groundwater elevation in the deep well, the vertical gradient is negative or downward. If the groundwater elevation in the shallow well is lower than the groundwater elevation in the deep well, the vertical gradient is positive or upward.

Little or no vertical gradient, 0.01 to -0.01 ft/ft, was observed in the monitoring well pairs screened in the upper and lower parts of the shallow zone (Table 3-3).

More pronounced vertical gradients, -0.03 to -0.12 ft/ft, were observed in the well clusters where wells were screened in the shallow and deep zones (Table 3-3). The vertical gradients were downward across the site, indicating that the downward migration of contaminants from the shallow part of the aquifer may be limited by a semi-confining layer and suggesting the potential for groundwater discharge to surface water bodies.

3.6.5 Hydraulic Conductivity

Hydraulic conductivity values for Site 1 were estimated using the data from slug tests conducted in selected monitoring wells at Site 3 (TtNUS, 2008) and Site 4 (TtNUS, 2007). A slug test data summary is included in Table 3-4. The geometric mean of the hydraulic conductivity values reported for shallow monitoring wells at Site 3 and Site 4 is approximately 23.5 feet per day (ft/day). The geometric mean of

the hydraulic conductivity values reported for deep monitoring wells at Site 4 is approximately 3.2 ft/day. The slug test data indicate two orders of magnitude variation in hydraulic conductivity in the surficial aquifer.

3.6.6 Horizontal Groundwater Flow Velocity

Potential horizontal movement of groundwater at the site may be estimated in terms of transportation by natural flow in the saturated zone, assuming groundwater flow follows Darcy's Law. Darcy's Law is expressed as:

$$V \equiv \frac{(K * I)}{\eta}$$

where:

- V = average velocity
- K = hydraulic conductivity
- η = effective porosity
- I = average hydraulic gradient

Data from soil borings advanced during the DPT investigation indicate that fine-grained sand and silty or clayey sand are typical lithologies at the site. Review of standard literature suggests that a representative effective porosity for this lithology is approximately 30 percent (Heath, 1983).

The horizontal gradient in the shallow surficial aquifer in the western half of Site 1 was 0.003 ft/ft. With a hydraulic conductivity of 23.5 ft/day, the groundwater flow velocity in this part of Site 1 was 0.24 ft/day.

The horizontal gradient in the shallow surficial aquifer in the eastern half of Site 1 was 0.002 ft/ft. With a hydraulic conductivity of 23.5 ft/day, the groundwater flow velocity in this part of Site 1 was 0.16 ft/day.

The horizontal gradient in the deep surficial aquifer at Site 1 was 0.008 ft/ft. With a hydraulic conductivity of 3.2 ft/day, the groundwater flow velocity in this aquifer zone at Site 1 was 0.09 ft/day.

3.6.7 Regional Hydrogeology

In the Gulfport area, geologic units containing fresh water are of Miocene to Recent age. Aquifers are composed predominantly of sand beds that are irregular in thickness and horizontal extent. There are no thick, consistently traceable confining units between aquifers at these shallow depths (Shows, 1970).

The uppermost aquifer is the surficial aquifer, which is composed of undifferentiated alluvium and Pamlico Sand terrace deposits (Recent to Pleistocene in age). The Pamlico Sand formation is approximately 60 to 70 feet thick and is composed of fine sands and clay. Depth to groundwater in the surficial aquifer is variable depending on local topography and precipitation, but generally ranges from 4 to 7 feet bls. In the northern part of the Base, shallow groundwater flow in the surficial aquifer is north toward Turkey Creek, which empties into Bernard Bayou and eventually into the Gulf of Mexico via the Mississippi Sound. Generally, this aquifer is not used for potable water supply.

Beneath the surficial aquifer are hydrogeologic units which include aquifers in the Citronelle Formation and Graham Ferry Formation (Pliocene) and Pascagoula, Hattiesburg, and Catahoula Formations (Miocene). Boundaries between the aquifers are vaguely defined, if at all. These aquifers are composed of sands and discontinuous clays and are a major source of potable water in the Gulfport area.

Wells in the Citronelle Formation are used in Harrison County for both domestic and industrial water supply. Supply wells in the Upper and Lower Pascagoula Formations provide the majority of fresh water used in the Coastal Plain. The Hattiesburg Formation becomes increasingly brackish with depth, and salt water is encountered near the base of this unit (approximately 2,000 feet below sea level).

3.7 DEMOGRAPHY AND LAND USE

NCBC Gulfport is located in the western part of the City of Gulfport, Mississippi, in southeastern Harrison County. Biloxi, the largest city in Harrison County, is located 7 miles east of Gulfport, and Pass Christian is located 7 miles to the west.

NCBC Gulfport is an active military facility with a primary mission of supporting battalions of the NCF and the storage and maintenance of pre-positioned War Reserve Material Stock. NCF support consists of both homeport services and deployed support. Additional missions include tenant support and services to other activities in the region.

Land uses on base include training activities, equipment and materials storage, maintenance areas, recreational facilities, and residential housing for military personnel. Land use in off-base areas adjacent to NCBC Gulfport is primarily residential.

Site 1 is located adjacent to the base golf course; therefore, recreational users and trespassers, as well as site and maintenance workers, are expected to use the site.

3.8 ECOLOGY

Site 1 is located in the northwestern corner of the base. Areas to the east and south of the site are developed and used as training facilities. The area to the north and west include parts of the Pine Bayou Golf Course.

3.8.1 Aquatic Habitats

The drainage ditches at Site 1 are part of the network of interconnected ditches and canals that convey storm water on the base. The on-base ditches at NCBC Gulfport are generally straight and uniform in width, lacking the morphological properties of natural streams. Aquatic plants may grow in stable sand and gravel banks near and below water levels. Wading birds, fish, and benthic organisms have been observed in the ditches and canals on the base.

3.8.2 Terrestrial Habitats

Ground cover at the site is predominantly maintained grass, with planted pines, and several small buildings. Large trees are present throughout the site. On-site wildlife may forage at Site 1, but due to lack of suitable cover on the golf course, wildlife use is assumed to be temporary. Snakes, turtles, frogs, and Canada geese have been observed at the site.

3.8.3 Species of Concern

A request for a listing of species of concern was sent to the Heritage Program of the Mississippi Museum of Natural Science. The response from the Heritage Program, dated February 24, 2003, cited no occurrences of state or federal listed or proposed endangered or threatened plants or animals on NCBC Gulfport.

4.0 NATURE AND EXTENT OF CONTAMINATION

As stated in Section 1.0, the field and laboratory analytical data collected for the RI provide the information necessary to: (1) adequately characterize the nature and extent of contamination at the site, (2) define site dynamics, and (3) determine site risks to human and ecological receptors. Section 4.0 presents the characterization of the nature and extent of contamination at the site by:

- Identifying the types of materials disposed of during landfill operations.
- Evaluating the extent of potential sources of contaminants that could impact receptors outside the boundary of the containment area (cap).
- Identifying contaminants based on screening against state and federal criteria for exposure to human receptors, ecological receptors, and potential receiving media.

The screening criteria used to evaluate the nature and extent of contamination in environmental media at Site 1 included the following:

- MDEQ Tier 1 TRGs
- Oak Ridge National Laboratory (ORNL) Regional Screening Levels (RSLs)
- Soil Screening Levels (SSLs) for migration to air and groundwater
- USEPA Groundwater Volatilization Criteria (GVCs)
- USEPA Region 4 Ecological Screening Values (ESVs)

The screening criteria used to evaluate environmental media sampled at Site 1 are summarized in Table 4-1. The decision points used to identify the COPCs included:

- Chemicals detected at concentrations greater than the screening criteria (Table 4-1).
- Non-carcinogens detected at a concentration greater than 1/10 of their direct exposure screening criteria [representing a hazard quotient (HQ) of 0.1 as a conservative approach to include cumulative effects].
- Chemicals without established ESVs [retained for evaluation in the screening level ecological risk assessment (SLERA)].

The Application of the CERCLA Municipal Landfill Presumptive Remedy to Military Landfills (USEPA, 1996c) identifies the waste characteristics of military landfills that allow the application of the presumptive remedy guidance. The guidance states that appropriate characteristics include the following:

- Risks are low-level except for “hot spots.”
- Treatment of wastes is usually impractical due to the volume and heterogeneity of the waste.
- Waste types include household, commercial, non-hazardous sludge, and industrial waste solids.
- Lesser quantities of hazardous wastes are present compared to municipal wastes.
- Land application units, surface impoundments, injection wells, and waste piles are **not** included.

The guidance further states that it is anticipated that military landfills will have industrial solid waste, paints (and paint thinners), pesticides, transformer oils, and other solvents in relatively low proportion to the volume of municipal wastes – including construction debris, commercial/household type garbage, and yard wastes. The types of waste that would exclude a military site from presumptive remedy consideration include chemical warfare agents, munitions, and other explosives. Based on the site history, operational history of the base, and results from previous investigations, Site 1 qualifies for presumptive remedy consideration.

To specifically examine the contaminant sources at Site 1 and to begin the definition of site dynamics, the following sections describe the types, distribution, and trends of contaminants present in the various media.

4.1 WASTE DISPOSAL BOUNDARY AND CONTAMINANT SOURCES

The first requirements of the presumptive remedy RI for landfills were to adequately characterize the extent of the disposal area and to determine if the types of wastes at the site are appropriate for a presumptive remedy.

4.1.1 Waste Disposal Boundary

At Site 1, the waste disposal boundary was established by evaluating the results of the magnetometer (shown on Figure 4-1) and EM-31 (shown on Figure 4-2) surveys.

Visual observations of soil samples at DPT sampling locations and monitoring well locations further aided in delineation of the waste disposal area. In addition, these observations confirmed that the geophysical survey was effective in accurately determining the waste disposal boundaries of the landfill.

4.1.2 Contaminant Sources

A review of disposal practices and interviews with site workers during the IAS (Envirodyne Engineering, 1985) indicated that liquid chemical wastes generated by the base were disposed of at Site 1 from 1942 to 1948. These liquid wastes included fuels, oils, and solvents.

4.2 SOILS AND VADOSE ZONE

The passive soil gas survey and quick-turn soil screening were used to look for potential hot-spots associated with the waste disposal areas identified by the geophysical survey. Additional full suite soil sampling was conducted to characterize surface and subsurface soil conditions. The landfill gas screening and geotechnical sampling were used for a preliminary evaluation of existing conditions in the landfill.

4.2.1 Passive Soil-Gas Survey

The passive soil-gas survey was conducted to provide a qualitative evaluation of the presence or absence of volatile contaminants in soil and shallow groundwater. The passive soil-gas methodology does not distinguish between contaminants present in soil, groundwater, or both media. The concentrations of contaminants reported by this method do not directly correlate to quantified concentrations in soil or groundwater samples used for risk-based screening.

The passive soil gas survey detected low levels of total petroleum hydrocarbons (TPH) at each of the sample locations. The highest concentration was reported in sample 560070, located near the center of the disposal area. Because the area is planted with pine trees, it is likely that naturally occurring terpenes produced the widespread detections of TPH in the soil gas samples.

Detections of other compounds were limited to two sample locations. Low levels of the alkanes undecane and tridecane were detected at the 560070 location. Toluene was detected at the 560069 sample location.

Soil and groundwater samples collected for quantitative analysis in the vicinity of these two soil gas samples did not have detectable levels of the compounds reported in the soil gas samples.

4.2.2 Surface Soil

The current surface soil cover at Site 1 was brought in following landfill closure. The source of the fill material is unknown. Surface soil samples were collected from a depth of 0 to 1 foot at 19 locations and

from a depth of 0 to 2 feet at 2 locations at Site 1 and were analyzed for TCL VOCs, TCL SVOCs, TCL pesticides and PCBs, Appendix IX chlorinated herbicides, and TAL inorganics. Analytes detected in the surface soil samples are summarized in Table 4-2, and results exceeding the TRG are presented on Figure 4-3.

4.2.2.1 Volatile Organics

Three VOCs were reported in one or more surface soil samples collected at Site 1.

Tetrachloroethene was detected in two surface soil samples, 01SS13701 and 01SS42001, at estimated concentrations of 0.28 J and 0.22J micrograms per kilogram (ug/kg), which are less than the TRGs (unrestricted – 11,900 ug/kg and restricted – 18,200 ug/kg) and the RSL (570 ug/kg). The tetrachloroethene concentrations in both these samples were greater than the SSL for soil leaching to groundwater of 0.052 ug/kg. The detected concentrations of tetrachloroethene were less than the ESV (10 ug/kg).

2-Butanone was detected at concentrations ranging from 1.8 to 4 ug/kg, which are less than the direct exposure and migration pathways screening criteria for human health. An ESV has not been established for 2-butanone.

4-methyl-2 pentanone was detected at concentrations ranging from 0.71 to 1.2 ug/kg, which are less than the direct exposure and migration pathways screening criteria for human health. An ESV has not been established for 4-methyl-2 pentanone.

4.2.2.2 Semivolatile Organics

Benzo(b)fluoranthene was detected in one surface soil sample, 01SS04QT at a concentration of 78 J ug/kg which is greater than the SSL for soil leaching to groundwater of 47 ug/kg and less than the TRG, RSL, and ESV.

Caprolactam was detected in surface soil samples at concentrations ranging from 140 to 300 J ug/kg, which are orders of magnitude less than the TRG, the RSL, and SSL. An ESV has not been established for caprolactam.

4.2.2.3 Pesticides/PCBs

Dieldrin was the only pesticide detected in Site 1 surface soil samples at a concentration exceeding human health direct exposure criteria (TRG and RSL). Dieldrin was detected in 98 of the 21 soil samples.

Dieldrin was detected in one surface soil sample (01SS02501) at a concentration of 460 J ug/kg, which is greater than the restricted TRG (358 ug/kg) and the residential RSL (30 ug/kg), as well as the ESV (0.5 ug/kg) and the SSL for leaching to groundwater (0.09 ug/kg).

Dieldrin concentrations at six of the sample locations, 01SS0801 (01SS0901, 01SS1001, 01SS1101, 01SS1401, and 01SS01501) ranged from 0.55 J ug/kg to 15 J ug/kg, which are greater than the ESV and SSL for leaching to groundwater, but less than the direct exposure criteria (TRGs and RSL). The dieldrin concentration in surface soil sample 01SS13701, 0.36 J ug/kg, exceeded the ESV only.

Aldrin was detected in 3 of the 21 surface soil samples. Aldrin was detected in one surface soil sample (01SS01701) at a concentration of 6.3 J ug/kg, which is greater than the ESV (2.5 ug/kg) and the SSL for leaching to groundwater (0.84 ug/kg). Aldrin concentrations detected in the other two samples, [01SS02501 (0.29 J ug/kg) and 01SS4201 (0.16 J ug/kg)] were less than the screening criteria.

Heptachlor epoxide concentrations at five of the sample locations (01SS1001, 01SS1101, 01SS01401, 01SS02401, and 01SS02501) ranged from 0.25 J ug/kg to 1.7 J ug/kg, which are greater than the SSL for leaching to groundwater (0.079 ug/kg), but less than the direct exposure criteria (TRGs and RSL). An ESV has not been established for heptachlor epoxide.

Isomers of the pesticide benzene hexachloride (BHC) were detected in one or more samples at concentrations greater than the SSL for leaching to groundwater. Alpha BHC was detected in one surface soil sample (01SS05QT) at a concentration of 0.26 J ug/kg, which is greater than the SSL of 0.074 ug/kg. Beta BHC was detected in five of the surface soil samples, but only the concentration reported for 01SS0801 (0.36 J ug/kg) was greater than the SSL of 0.26 ug/kg. Delta BHC was detected in one surface soil sample (01SS01401) at a concentration of 0.26 J ug/kg which is greater than the SSL of 0.074 ug/kg. Gamma BHC (lindane) was detected in one surface soil sample, the field duplicate 01SS013901-D, at a concentration of 0.23 J ug/kg, which is greater than the ESV of 0.05 ug/kg, but less than the SSL of 0.43 ug/kg.

Aroclor 1260 was detected in one surface soil sample, 01SS1001 at a concentration of 17 J ug/kg which is greater than the SSL of 14 ug/kg, but less than the residential TRG (1,000 ug/kg), RSL (220 ug/kg), and ESV (20 ug/kg).

Endrin aldehyde was detected in two surface soil samples, 01S06QT at 0.31 J ug/kg and 01SS1001 at 2 J ug/kg. These concentrations are less than the direct exposure and migration pathways screening criteria. An ESV has not been established for endrin aldehyde.

Several pesticides were detected at concentrations less than direct exposure or migration pathway screening criteria, but do not have established ESVs; endosulfan II (6 samples), endosulfan sulfate (1 sample), heptachlor (1 sample), and methoxychlor (4 samples).

4.2.2.4 Herbicides

2,4,5-trichlorophenoxyacetic acid (2,4,5-T) was detected in surface soil samples at concentrations ranging from 1.2 to 6 ug/kg, which are orders of magnitude less than the TRG, the RSL, and SSL. An ESV has not been established for 2,4,5-T.

Dinoseb was detected in one surface soil sample at a concentration of 8.8 ug/kg, which is orders of magnitude less than the TRG, the RSL, and SSL. An ESV has not been established for dinoseb.

4.2.2.5 Inorganics

Metals were frequently detected in the soil samples collected at Site 1 (see Table 4-2).

Arsenic was the only metal detected in Site 1 surface soil samples at concentrations exceeding human health direct exposure criteria (TRGs and RSL). Arsenic was detected in 19 of the 21 soil samples.

Arsenic was detected in two surface soil samples at concentrations greater than the restricted TRG of 3.82 mg/kg:

01SS04QT 4.8 mg/kg
01SS0701 3.9 mg/kg

Arsenic concentrations in 14 of the 21 surface soil samples were greater than the unrestricted TRG (0.426 mg/kg), the residential RSL (0.39 mg/kg) and the SSL for soil leaching to groundwater (0.0013 mg/kg – risk based and 0.29 mg/kg – MCL based):

01SS01QT	0.83 mg/kg	01SS01501	1 mg/kg
01SS02QT	1.5 mg/kg	01SS01701	2.7 mg/kg
01SS03QT	1.1 mg/kg	01SS02401	0.78 mg/kg
01SS05QT	1.6 mg/kg	01SS02501	1.1 mg/kg
01SS06QT	1.3 mg/kg	01SS13701	1.9 mg/kg
01SS1001	3.5 mg/kg	01SS13801	1.2 mg/kg
01SS1101	1.7 mg/kg	01SS13901-D	1.5 mg/kg
01SS1201	1.3 mg/kg	01SS42001	1.5 mg/kg
01SS01401	1.8 mg/kg		

Pettry and Switzer (2001) evaluated the arsenic concentrations in different soil resource areas. Samples of soils collected from Coastal Flatwoods areas had arsenic concentrations ranging from 0.37 to 14.78 mg/kg, with a mean arsenic concentration of 4.42 mg/kg. The detected concentrations of arsenic in the Site 1 soil samples, 0.78 to 4.8 mg/kg, are within this range of concentrations and all but one (01SS04QT – 4.8 mg/kg) was less than the mean concentration reported by Pettry and Switzer.

Aluminum was detected in each of the surface soil samples at concentrations ranging from 1,770 to 12,300 mg/kg. Each of the aluminum detections were at greater concentration than the ESV of 50 mg/kg, but less than the TRG, RSL, and SSLs.

Antimony was reported in two of the surface soil samples, 01SS0801 – 1.1 J mg/kg and 01SS42001 – 3.6 J mg/kg. These concentrations are greater than the SSL for leaching to groundwater, 0.66 mg/kg, and the ESV, 0.27 mg/kg, but less than the TRG and RSL.

Cobalt was detected in one soil sample (01SS1701) at a concentration of 6.8 mg/kg, which is greater than the SSL for leaching to groundwater, 0.49 mg/kg. This concentration is less than the TRG, RSL, and ESV.

Iron was detected in each of the surface soil samples at concentrations ranging from 546 to 9,050 mg/kg. Each of the iron detections were at greater concentration than the ESV of 200 mg/kg. All but one of the reported iron concentration were greater than the SSL for leaching to groundwater of 640 mg/kg. Iron concentrations were less than the TRG and RSL.

Manganese was detected in each of the surface soil samples at concentrations ranging from 1 to 358 mg/kg. The reported manganese concentration in 01SS1701 (358 mg/kg) is greater than the ESV (220 mg/kg) and the SSL for leaching to groundwater (57 mg/kg). The manganese concentrations in two other samples (01SS1401 – 67.4 mg/kg and 01SS13701 – 89 mg/kg) only exceeded the SSL for leaching to groundwater. Manganese concentrations were less than the TRG and RSL.

Chromium was detected in each of the surface soil samples at concentrations ranging from 2.2 to 11 mg/kg. Each of the chromium detections was at greater concentration than the SSL for leaching to groundwater of 2.1 mg/kg. Chromium concentrations were less than the TRG, RSL, and ESV.

Copper was detected in 19 of the 21 surface soil samples at concentrations ranging from 1.4 to 210 mg/kg. Most of the reported copper concentrations were less than 10 mg/kg. The reported copper concentration in 01SS1501 (210 mg/kg) is greater than the ESV (28 mg/kg) and the SSL for leaching to groundwater, 51 mg/kg. Copper concentrations were less than the TRG and RSL.

Lead was detected in each of the surface soil samples at concentrations ranging from 3.2 to 70.6 mg/kg. The lead concentrations in eight samples were greater than the ESV, 11 mg/kg and the SSL for leaching to groundwater, 14 mg/kg. Lead concentrations were less than the TRGs and RSL.

Selenium was reported in four of the surface soil samples. The selenium concentrations detected in two of the surface soil samples (01SS05QT – 1 mg/kg and 01SS06QT – 1.3 mg/kg) are greater than the SSL for leaching to groundwater (0.95 mg/kg) and the ESV (0.52 mg/kg). The selenium concentrations detected in two other surface soil samples (01SSQT01 – 0.69 mg/kg and 01SS04QT – 0.71 mg/kg) were greater than the ESV. Selenium concentrations were less than the TRG and RSL.

Vanadium was detected in each of the surface soil samples at concentrations ranging from 2.7 to 16 mg/kg. The vanadium concentrations in 14 samples were greater than the ESV, 7.8 mg/kg. Vanadium concentrations were less than the TRG, RSL, and SSLs.

Zinc was detected in each of the surface soil samples at concentrations ranging from 1.7 to 89 mg/kg. The zinc concentrations in two samples (01SS1001 – 54.8 mg/kg and 01SS13701 – 89 mg/kg) were greater than the ESV, 46 mg/kg. Zinc concentrations were less than the TRG, RSL, and SSLs.

4.2.2.6 Summary of Surface Soil Analytical Results

Chemicals detected in surface soil at Site 1 appear to have resulted from typical maintenance activities and the addition of fill from an unknown source. Relatively few VOCs were detected in Site 1 surface soil samples and concentrations were low. A range of pesticides were detected, but many were only found in one sample. Metals were detected frequently in the surface soil samples. Table 4-3 details the screening of COPCs for Site 1 surface soil. The chemicals retained as COPCs for evaluation in the remedial actions (RAs) are summarized below:

- Direct Exposure (carcinogen) – dieldrin and arsenic
- Direct Exposure (non-carcinogen) – aluminum, antimony, cobalt, iron, and manganese
- Leaching to groundwater – tetrachloroethene, benzo(b)fluoranthene, Aroclor-1260, aldrin, alpha chlordane, BHC isomers, dieldrin, heptachlor epoxide, antimony, arsenic, chromium, cobalt, iron, lead, manganese, and selenium.
- Ecological Receptors – aldrin, gamma BHC, dieldrin, endrin aldehyde, aluminum, antimony, copper, iron, lead, manganese, selenium, vanadium, and zinc

- Ecological Receptors (No ESV) – 2-butanone, 4-methyl-2-pentanone, caprolactam, chlordane, endosulfan II, endosulfan sulfate, heptachlor, heptachlor epoxide, methoxychlor, 2,4,5-T, and dinoseb

4.2.3 Subsurface Soil

One subsurface soil sample was collected from each of 10 drilling locations and analyzed for VOCs (Table 4-4). The drilling locations were selected to coincide with the margins of the waste area and provide a cross-sectional characterization of the shallow subsurface across the site. Six additional soil samples were collected adjacent to the ditch on the east side of Site 1. Three of the samples were analyzed for a full suite of analytes (Table 4-4). The other three locations were analyzed only for PCBs (Table 4-4).

4.2.3.1 Volatile Organics

The VOCs detected in the subsurface soil samples, chloromethane (1 sample), 2-butanone (2 samples), 4-methyl-2-pentanone (1 sample), and carbon disulfide (1 sample), were all at concentrations less than the screening criteria.

4.2.3.2 Semivolatile Organics

SVOC concentrations in the three ditch bank samples analyzed for SVOCs were less than the laboratory detection limits.

4.2.3.3 Pesticides/PCBs

The PCB Aroclor-1242 was detected in one of the ditch bank samples (01SBDIT02) at a concentration of 2,400 J ug/kg. This reported concentration was greater than the unrestricted TRG (1,000 ug/kg), the RSL (220 ug/kg), and the SSL for leaching to groundwater (3 ug/kg). PCB concentrations in the other ditch bank samples were less than the laboratory detection limit.

Beta BHC was reported in two of the ditch bank samples (01SBDIT01 – 0.32 J ug/kg and 01SBDIT02 – 63 J ug/kg) at concentrations greater than the SSL for leaching to groundwater (0.026 ug/kg) but less than the unrestricted TRG (355 ug/kg), the RSL (270 ug/kg), and the SSL for soil to air (16,000 ug/kg).

Other BHC isomers detected in 01SBDIT02 were alpha BHC - 4.2 J ug/kg and delta BHC – 34 J ug/kg, at concentrations greater than the SSL for leaching to groundwater, 0.074 ug/kg, but less than the unrestricted TRG (101 ug/kg), the RSL (77 ug/kg), and the SSL for soil to air (750 ug/kg). Note that the screening criteria for alpha BHC were used to evaluate the delta BHC results.

Dieldrin was reported in two of the ditch bank samples, 01SBDIT01 – 0.43 J ug/kg and 01SBDIT02 – 0.85 R ug/kg. Note that the result for 01SBDIT03 was R-flagged during data validation for laboratory quality issues. Because most of the screening criteria for dieldrin are two to three orders of magnitude greater than the R-flagged result, it has been treated as a detection of 0.85 ug/kg for this evaluation. The detected dieldrin concentrations in these two samples were greater than the SSL for leaching to groundwater (0.09 ug/kg), but less than the unrestricted TRG (39.9 ug/kg), the RSL (30 ug/kg), and the SSL for soil to air (1,100 ug/kg).

Heptachlor epoxide was detected in two of the ditch bank soil samples (01SBDIT01 – 0.33 J ug/kg and 01SBDIT02 – 6.2 J ug/kg) at concentrations greater than the SSL for leaching to groundwater, 0.079 ug/kg.

4.2.3.4 Herbicides

Herbicide concentrations in the three ditch bank samples analyzed for herbicides were less than the laboratory detection limits.

4.2.3.5 Inorganics

Arsenic was the only metal detected in the canal bank soil samples collected at Site 1 with concentrations exceeding human health direct exposure criteria. Arsenic was reported in two of the ditch bank soil samples, 01SBDIT01 – 2 mg/kg and 01SBDIT03 – 1.3 mg/kg. These concentrations are greater than the unrestricted TRG (0.426 mg/kg), the RSL (0.39 mg/kg) and the SSL for leaching to groundwater (0.0013 mg/kg) but less than the restricted TRG (3.82 mg/kg). The detected concentrations of arsenic in the Site 1 soil samples are within the range of concentrations for Coastal Flatwoods areas (Pettry and Switzer, 2001) and are less than the mean concentration.

Chromium was detected in each of the ditch bank soil samples at concentrations ranging from 3 to 9.8 mg/kg. Each of the chromium detections was at greater concentration than the SSL for leaching to groundwater of 2.1 mg/kg. Chromium concentrations were less than the TRG and RSL.

Iron was detected in each of the ditch bank soil samples at concentrations ranging from 908 to 2,060 mg/kg. Each of the iron detections was at a greater concentration than the SSL for leaching to groundwater of 640 mg/kg. Iron concentrations were less than the TRG and RSL.

4.2.3.6 Summary of Subsurface Soil Analytical Results

Relatively few VOCs were detected in Site 1 subsurface soil samples and concentrations were low. A range of pesticides were detected, but many were found only in one sample. Metals were detected frequently in the subsurface soil samples. Table 4-5 details the screening of COPCs for Site 1 subsurface soil. The chemicals retained as COPCs for evaluation in the human health risk assessment (HHRA) are summarized below:

- Direct Exposure (carcinogen) – Aroclor-1242 and arsenic.
- Direct Exposure (non-carcinogen) – aluminum
- Leaching to groundwater – alpha chlordane, Aroclor-1242, beta BHC, delta BHC, dieldrin, heptachlor epoxide, arsenic, chromium, and iron

4.2.4 Landfill Gas Screening

The methane concentrations at the five vadose zone sampling locations at Site 1 were less than the instrument detection levels for both methane concentration (% CH₄) and LEL (Table 4-6).

4.2.5 Grain Size Analysis

Grain size samples of the current cover were evaluated to see if the current cover material was likely to have the geotechnical properties required for the low permeability layer. Each of the samples was predominantly sand, 73 percent to 83 percent, which suggests that current cover would require amendment to meet the low permeability criteria (Table 4-7).

4.3 GROUNDWATER

Groundwater samples were collected during two phases of investigation that included DPT groundwater sampling for VOC analysis and monitoring well sampling. DPT groundwater samples were analyzed to quantify concentrations of VOCs identified in the passive soil-gas survey. Monitoring wells were sampled for a full suite of analytes to further characterize groundwater conditions at the site.

The presumptive remedy strategy for Site 1 includes containment of the buried waste via a soil landfill cover for the waste disposal area. The goal of the groundwater sampling program was to provide the data necessary to answer the following questions:

- Is the waste observed in the landfill consistent with the use of the presumptive remedy?
- Do site dynamics support a containment strategy?
- Are there hot spots that require additional delineation?
- Will the hot spots require additional treatment?
- Should additional non-presumptive remedies be included in the containment alternatives?

The results of the groundwater investigations are discussed below.

4.3.1 DPT Groundwater Investigation

Groundwater samples were collected from 29 DPT locations (Figure 4-4) and analyzed for VOCs (Table 4-8). The samples were collected from locations across the entire waste disposal area, as well as upgradient, cross-gradient, and downgradient of the landfill. The initial sample collection focused on geophysical hot spots identified during the survey and subsequent locations were sampled to refine the delineation. Vertically, groundwater samples were collected from depths ranging from 6 to 45 feet bls.

The DPT VOC analytical results are discussed in Section 4.3.2.1, along with the monitoring well VOC results.

4.3.2 Monitoring Well Sampling

Groundwater samples were collected from 22 monitoring wells at Site 1 (Figure 4-4). The majority of the monitoring wells were screened in the shallow aquifer at depths of 30 feet or less. The monitoring well groundwater samples were analyzed for TCL VOCs, TCL SVOCs, TCL pesticides and PCBs, Appendix IX chlorinated herbicides, and TAL inorganics. Analytes detected in monitoring well samples are summarized in Table 4-9.

4.3.2.1 Volatile Organics

Tetrachloroethene was reported in five of the groundwater samples out of a total of 51 samples (29 DPT locations and 22 monitoring wells). Four of the DPT groundwater samples had detections of tetrachloroethene:

01TW0101	0.35 J micrograms per liter (ug/L)
01TW0301	0.41 J ug/L
01QT0401	0.54 J ug/L
01QT1501	0.26 J ug/L

Tetrachloroethene was detected in one monitoring well sample:

01GW2301 2.5 ug/L

Each of these tetrachloroethene detections was greater than the RSL, 0.11 ug/L. Only the concentration reported in the monitoring well sample 01GW2301, 2.5 ug/L was greater than the GVC of 1.1 ug/L. All of the detections were less than the TRG of 5 ug/L, which is based on the MCL.

Trichloroethene was reported in four of the groundwater samples. Two of the DPT groundwater samples had detections of trichloroethene:

01TW0101 0.51 J ug/L

01TW0301 0.32 J ug/L

Trichloroethene was detected in two monitoring well samples:

01GW2001 0.3 J ug/L

01GW2301 1.3 ug/L

Each of these trichloroethene detections was greater than the GVC, 0.053 ug/L. All of the detections were less than the TRG of 5 ug/L, which is based on the MCL and the RSL, 1.7 ug/L.

Other VOCs detected in one or more groundwater samples, cis-1,2-dichloroethene, chloromethane, acetone, 2-butanone, and carbon disulfide, were at concentrations less than the screening criteria.

4.3.2.2 Semivolatile Organics

Naphthalene was reported in one monitoring well sample (01GW2601) at a concentration of 6.7 J ug/L, exceeding the TRG of 6.2 ug/L and the RSL of 0.14 ug/L. Naphthalene was not detected in the other monitoring well groundwater samples.

Bis(2-ethylhexyl)phthalate was detected in five of the monitoring well samples at concentrations ranging from 1.7 J ug/L to 2 J ug/L, which are less than the TRG (6 ug/L) and the RSL (4.8 ug/L).

4.3.2.3 Pesticides/PCBs

4-4'-DDT was detected in one groundwater sample (01GW2401) at a concentration of 0.0068 J ug/L, which is less than the TRG (0.197 ug/L) and the RSL (0.2 ug/L).

Endrin aldehyde was detected in one groundwater sample (01GW1301) at a concentration of 0.0088 J ug/L, which is less than the TRG (2 ug/L) and the RSL (11 ug/L).

4.3.2.4 Herbicides

Silvex (2,4,5-TP) was reported by the laboratory in seven of the monitoring well samples at concentrations less than the screening criteria. Note that the result for three of the groundwater samples were R-flagged during data validation for laboratory quality issues. Because most of the screening criteria for Silvex are two to three orders of magnitude greater than the R-flagged results, they have been treated as detections for this evaluation.

4.3.2.5 Inorganics

Arsenic was detected in 2 of the 21 monitoring well samples, 01GW1401 at 19.1 ug/L and 01GW1501 at 14.2 ug/L. These concentrations are less than the TRG (50 ug/L), but exceed the RSL (0.045 ug/L). Both of these monitoring wells are located at the northwest corner of the site, on the west side of the ditch that parallels Colby Avenue.

Iron was detected in each of the monitoring well samples at concentrations ranging from 147 ug/L to 44,000 ug/L. Iron concentrations were greater than the TRG (11,000 ug/L) and the RSL (26,000 ug/L) in three monitoring well samples:

- 01GW1401 38,000 ug/L
- 01GW1501 44,000 ug/L
- 01GW2701 28,800 ug/L

Iron concentrations were greater than the TRG, but less than the RSL in two groundwater samples:

- 01GW0901 11,500 ug/L
- 01GW2001 13,900 ug/L

Four of these five locations are in the northern part of the investigation area, in the vicinity of the former catfish ponds.

Thallium was detected in one monitoring well sample (01GW1601) at a concentration of 4.1 ug/L, greater than the TRG (2 ug/L) and the RSL (2.4 ug/L).

Aluminum was detected in each of the monitoring well samples collected at Site 1. Reported aluminum concentrations ranged from 73.5 to 6,320 ug/L, which are less than the TRG (36,500 ug/L) and the RSL (37,000 ug/L).

Manganese was detected in each of the monitoring well samples collected at Site 1. Reported manganese concentrations ranged from 4.4 to 548 ug/L, which are less than the TRG (730 ug/L) and the RSL (880 ug/L).

Other metals and cyanide were at concentrations less than screening criteria.

4.3.3 Summary of Groundwater Analytical Results

Relatively few organic compounds were detected in Site 1 groundwater samples and concentrations were low. Metals were detected frequently in the groundwater samples. Table 4-10 details the screening of COPCs for Site 1 groundwater. The chemicals retained as COPCs for evaluation in the HHRA are summarized below:

- Direct Exposure (carcinogen) – tetrachloroethene, trichloroethene, naphthalene, and arsenic.
- Direct Exposure (non-carcinogen) – iron, manganese, and thallium
- Volatilization from groundwater – tetrachloroethene and trichloroethene

4.4 SURFACE WATER AND SEDIMENT

The surface water and sediment samples were analyzed for a full suite of analytes including TCL VOCs, TCL SVOCs, pesticides and PCBs, chlorinated herbicides, TAL metals and cyanide. Surface water analytical results are compared to the ESVs and the TRGs and RSLs for tap water, and the sediment analytical results are compared to the ESVs and the TRGs and RSLs for soil direct exposure.

4.4.1 Surface Water

Surface water samples co-located with sediment samples were collected from drainage ditches adjacent to Site 1 at the locations shown on Figure 4-5. Three of the surface water samples (01SW0101, 01SW0201, and 01SW0301) were collected from the shallow, concrete-lined drainage ditch on the west side of Site 1, parallel to Colby Avenue. At the time of sample collection, maintenance workers had cleaned the sediment from the ditch. The surface water samples were collected from within the ditch. Surface water sample 01SW0101 was collected from the mouth of a culvert, where the ditch had not

been cleaned. Two surface water samples (01SW0401 and 01SW0501) were located in the larger drainage ditch on the east side of Site 1 (Table 4-11).

4.4.1.1 Volatile Organics

Four VOCs were reported in one or more surface water samples collected at Site 1.

Acetone was detected in each of the samples with concentrations ranging from 3.4 to 5.1 ug/L, which are less than the TRG (608 ug/L) and the RSL (22000 ug/L). An ESV has not been established for acetone.

Carbon disulfide was detected in two of the surface water samples [01SW0201 and 01SW0301 (and field duplicate)] with estimated concentrations ranging from 0.19 to 0.20 ug/L, which are less than the TRG (1040 ug/L) and the RSL (1000 ug/L). An ESV has not been established for carbon disulfide.

1,1,2 trichloro-trifluoroethane was detected in one surface water sample (01SW0401) at a concentration of 6.6 ug/L, which is less than the TRG (59400 ug/L) and the RSL (59000 ug/L). An ESV has not been established for 1,1,2 trichloro-trifluoroethane.

Toluene was detected in one surface water sample (01SW0401) at an estimated concentration of 0.22 ug/L, which is less than the TRG (1000 ug/L), the RSL (2300 ug/L), and the ESV (175 ug/L).

4.4.1.2 Semivolatile Organics

One SVOC, caprolactam, was detected in each of the surface water samples at estimated concentrations ranging from 0.91 J to 2.1 J ug/L, which are less than the TRG (18,300 ug/L) and the RSL (18000 ug/L). An ESV has not been established for caprolactam.

4.4.1.3 Pesticides/PCBs

One pesticide, alpha chlordane, was detected in one surface water sample (01SW00401) at an estimated concentration of 0.004 J ug/L, which is less than the TRG (2 ug/L), the RSL (0.19 ug/L), and the ESV (0.0043 ug/L). PCBs were not reported in the surface water samples.

4.4.1.4 Herbicides

One herbicide, 2,4,5-TP (Silvex), was detected in four of the surface water samples at estimated concentrations ranging from 0.044 J ug/L to 0.067 J ug/L, which are less than the TRG (50 ug/L) and the RSL (290 ug/L). An ESV has not been established for Silvex.

4.4.1.5 Inorganics

Eleven metals were reported in one or more surface water samples collected at Site 1. Cyanide was not detected in the surface water samples.

Arsenic was detected in one surface water sample (01SW00101) at a concentration of 3.4 ug/L, which is greater than the RSL (0.045 ug/L), and less than the TRG (50 ug/L) and the ESV (190 ug/L).

Iron was detected in each of the surface water samples at concentrations ranging from 1,720 to 2,410 ug/L, which are less than the TRG (11000 ug/L) and the RSL (26000 ug/L) and greater than the ESV (1000 ug/L).

Aluminum was detected in each of the surface water samples at concentrations ranging from 430 to 1,690 ug/L, which are less than the TRG (36500 ug/L) and the RSL (37000 ug/L) and greater than the ESV (87 ug/L).

Lead was detected in two of the surface water samples [01SW0301 (and field duplicate) and 01SW0401] with concentrations ranging from 1.6 to 2.0 ug/L, which are less than the TRG (50 ug/L) and greater than the ESV (1.32 ug/L). An RSL has not been established for lead.

Barium was detected in each of the samples with concentrations ranging from 27.4 to 30.1 ug/L, which are less than the TRG (2000 ug/L) and the RSL (7300 ug/L). An ESV has not been established for barium.

Manganese was detected in each of the samples with concentrations ranging from 26.3 to 53.1 ug/L, which are less than the TRG (730 ug/L) and the RSL (880 ug/L). An ESV has not been established for manganese.

Zinc was detected in each of the samples with concentrations ranging from 5.4 to 10.4 ug/L, which are less than the TRG (11000 ug/L), the RSL (11000 ug/L), and the ESV 58.91 ug/L).

Calcium, magnesium, and sodium were detected in each of the surface water samples. Potassium was reported only in surface water sample 01SW0401. Because these elements are considered essential nutrients for both human and ecological receptors, screening criteria have not been established.

4.4.1.6 Summary of Surface Water Analytical Results

The concentrations of organic compounds (VOCs, SVOCs, pesticides, PCBs, and herbicides) reported in the surface water samples collected at Site 1 were less than the human health screening criteria; therefore, none of the organic compounds were retained as COPCs for the HHRA. The organic compounds detected in surface water samples at Site 1 that do not have established ESVs (1,1,2-trichloroethane, acetone, carbon disulfide, caprolactam, and silvex) were retained as COPCs for the SLERA (Table 4-12).

Arsenic was detected in one surface water sample (01SW0101) at a concentration greater than the RSL tap water criteria and is retained as a COPC in the HHRA. Iron concentrations in all the surface water samples were less than the TRGs and RSL. However, iron concentrations were greater than 10 percent of the TRG; therefore, iron will be evaluated as a non-carcinogenic COPC in the HHRA.

Aluminum, iron and lead were reported in Site 1 surface water samples at concentrations greater than the ESVs and are retained as ecological COPCs. Barium and manganese were retained as COPCs for the SLERA because ESVs have not been established for these metals.

4.4.2 Sediment

Sediment samples were collected from drainage ditches and swales adjacent to Site 1 (Figure 4-5). Five co-located surface water and sediment samples were collected for the RI. Three of the sample locations (01SD0101, 01SD0201, and 01SD0301) were collected from or adjacent to the shallow, concrete-lined drainage ditch on the west side of Site 1, parallel to Colby Avenue. At the time of sample collection, maintenance workers had cleaned the sediment from the ditch. Therefore, at locations 01SD0201 and 01SD0301, sediment was collected from the locations where shallow drainage swales from Site 1 intersected the concrete-lined ditch. Sediment sample 01SD0101 was collected from the mouth of a culvert, where the ditch had not been cleaned. Two surface water and sediment samples (01SW/SD0401 and 01SW/SD0501) were collected in the larger drainage ditch on the east side of Site 1 (Table 4-13).

4.4.2.1 Volatile Organics

VOCs were detected in most of the sediment samples at concentrations less than the human health screening criteria.

2-Butanone was detected in four of the five sediment samples with concentrations ranging from 5.8 to 80 ug/kg, which are less than the unrestricted TRG (84,500 ug/kg) and the RSL (28,000,000 ug/kg). An ESV has not been established for 2-butanone.

Acetone was detected in two of the five sediment samples with concentrations ranging from 28 to 220 ug/kg, which are less than the unrestricted TRG (38,000 ug/kg) and the RSL (61,000,000 ug/kg). An ESV has not been established for acetone.

Toluene was detected in one sediment sample at an estimated concentration of 33 J ug/kg, which is less than the unrestricted TRG (7,820,000 ug/kg) and the RSL (5,000,000 ug/kg). An ESV has not been established for toluene.

4.4.2.2 Semivolatile Organics

PAHs were detected in only in sediment sample 01SD0101. The benzo(a)pyrene concentration in this sample, 190 J ug/kg, was greater than the unrestricted TRG (87.5 ug/kg), the RSL (15 ug/kg) and the ESV (88.8 ug/kg). Benzo(b)fluoranthene was reported in this sample at a concentration of 330 J ug/kg, which is greater than the RSL of 150 ug/kg.

Other PAHs detected in this sample at concentrations greater than the ESV, but less than the TRGs and RSL include:

- Chrysene – 400 J ug/kg (ESV = 182 ug/kg)
- Fluoranthene – 1,300 J ug/kg (ESV = 113 ug/kg)
- Phenanthrene – 360 J ug/kg (ESV = 86.7 ug/kg)
- Pyrene – 930 J ug/kg (ESV = 153 ug/kg).

Bis(2-ethylhexyl)phthalate was detected in each of the sediment samples at concentrations less than the TRGs and RSL. The reported concentration in sediment sample 01SD0101 of 450 J ug/kg was greater than the ESV of 182 ug/kg.

4-methylphenol was detected in 01SD0101 at a concentration of 420 J ug/kg which is less than the unrestricted TRG (391,000 ug/kg) and the RSL (310,000 ug/kg). An ESV has not been established for 4-methylphenol.

4.4.2.3 Pesticides/PCBs

Pesticides were detected at low levels in each of the sediment samples. Concentrations were less than human health screening criteria.

Chlordane (total) exceeded the ESV of 1.7 ug/kg at three of the sediment sample locations.

- 01SD0101 – 9.5 ug/kg
- 01SD0401 – 5.7 ug/kg
- 01SD0501 – 7 ug/kg

These samples were collected from the ditches on the east and west sides of Site 1 which receive from input from areas upstream of Site 1. Chlordane concentrations in 01SD0201 or 01SD0301, which were collected from swales on the west side of Site 1 and only receive input from Site 1, were less than the ESV.

Several pesticides were detected at concentrations less than direct exposure screening criteria, but do not have established ESVs; aldrin (1 sample), alpha BHC (1 sample), delta BHC (1 sample), and heptachlor epoxide (1 sample).

PCB concentrations in the sediment samples were less than the laboratory detection limits.

4.4.2.4 Herbicides

Herbicide concentrations in the sediment samples were less than the laboratory detection limits.

4.4.2.5 Inorganics

Arsenic was the only metal detected in Site 1 sediment samples at concentrations exceeding human health direct exposure criteria (TRGs and RSL). Arsenic was detected in 4 of the 5 sediment samples. Arsenic was detected in one sediment sample at a concentration greater than the restricted TRG of 3.82 mg/kg and the ESV of 7.24 mg/kg.

- 01SD0101 19.8 J mg/kg

Arsenic concentrations in 3 of the 5 sediment samples were greater than the unrestricted TRG (0.426 mg/kg) and the residential RSL (0.39 mg/kg).

- 01SD0201 1.37 mg/kg
- 01SD0401 0.81 mg/kg
- 01SD0501 1.5 mg/kg

Aluminum was detected in each of the sediment samples at concentrations ranging from 1,000 to 17,200 mg/kg. Each of the aluminum detections were less than the TRGs and RSL. An ESV has not been established for aluminum in sediment.

Iron was detected in each of the sediment samples at concentrations ranging from 650 mg/kg to 28,100 J mg/kg. The iron concentration reported for 01SD0101 (28,100 J mg/kg) was greater than the unrestricted TRG of 23,500 mg/kg, but less than the RSL of 55,000 mg/kg and the restricted TRG of 613,000 mg/kg. An ESV has not been established for iron in sediment.

Manganese was detected in each of the samples with concentrations ranging from 1.5 mg/kg to 295 J mg/kg, which are less than the TRG (1,560 mg/kg) and the RSL (1,800 mg/kg). An ESV has not been established for manganese in sediment.

Lead was detected in two sediment samples (01SD0101 at 32.1 J mg/kg and 01SD0401 at 31 mg/kg) which are greater than the ESV of 30.2 mg/kg, but less than both the unrestricted TRG and RSL (400 mg/kg).

Vanadium was detected in each of the samples with concentrations ranging from 1.4 to 32.2 J mg/kg, which are less than the TRG (548 mg/kg) and the RSL (390 mg/kg). An ESV has not been established for vanadium in sediment.

Zinc was detected in each of the sediment samples at concentrations ranging from 4.2 mg/kg to 132 J mg/kg. The zinc concentration reported for 01SD0101 (132 J mg/kg) was greater than the ESV of 124 mg/kg, but less than the RSL of 23,000 mg/kg and the unrestricted TRG of 23,500 mg/kg.

Barium was detected in each of the samples with concentrations ranging from 5.3 to 61.2 mg/kg, which are less than the TRG (5,480 mg/kg) and the RSL (15,000 mg/kg). An ESV has not been established for barium.

Beryllium was reported in one sediment sample (01SD0101) at a concentration of 1.1 J mg/kg, which is less than the unrestricted TRG (156 mg/kg) and the RSL (160 mg/kg). An ESV has not been established for beryllium.

4.4.2.6 Summary of Sediment Analytical Results

Relatively few VOCs were detected in Site 1 sediment samples and concentrations were low. A range of pesticides and SVOCs were detected, but many were found only in one sample. Metals were detected

frequently in the sediment samples. Table 4-14 details the screening of COPCs for Site 1 sediments. The chemicals retained as COPCs for evaluation in the RAs are summarized below:

- Direct Exposure (carcinogen) – benzo(a)pyrene, benzo(b)fluoranthene, and arsenic.
- Direct Exposure (non-carcinogen) – aluminum, iron, and manganese.
- Ecological Receptors – chrysene, fluoranthene, phenanthrene, pyrene, bis(2-ethylhexyl)phthalate, and chlordane.
- Ecological Receptors (No ESV) – 2-butanone, acetone, toluene, aldrin, 4-methylphenol, diethyl phthalate, benzo(b)fluoranthene, benzo(k)fluoranthene, BHC isomers, heptachlor epoxide, aluminum, barium, beryllium, iron, manganese, and vanadium.

4.5 AIR

Air samples for laboratory analysis were not collected from Site 1 during the RI because the concentrations of volatile contaminants previously detected in soil and groundwater were relatively low. Air monitoring was conducted during the site investigation to identify potential exposure to higher concentrations of volatile contaminants.

To determine the potential for migration of soil contaminants to the atmosphere, the contaminant concentrations were compared to the USEPA SSLs. SSLs have been established for various volatiles, pesticides/PCBs, and metals. Concentrations of these classes of analytes that were detected in soil at Site 1 were less than the default SSL values.

USEPA groundwater volatilization criteria have been established for many of the VOCs detected in groundwater at Site 1. Chemicals that were reported in one or more groundwater samples at concentrations greater than the default criteria, indicating the potential for migration and accumulation of vapors from the groundwater, were retained as COPCs.

4.6 NATURE AND EXTENT CONCLUSIONS

One of the primary objectives of the RI was to evaluate the nature and extent and the impact of the waste disposal at Site 1, and to determine if the resulting site conditions meet the requirements to continue to pursue the current presumptive remedy strategy.

The *Application of the CERCLA Municipal Landfill Presumptive Remedy to Military Landfills* (USEPA, 1996c) identifies the waste characteristics of military landfills that allow the application of the Presumptive Remedy guidance. The guidance states that appropriate characteristics include:

- Risks are low-level except for "hot spots." The results of sampling were generally below screening levels.
- Treatment of wastes is usually impractical due to the volume and heterogeneity of the waste. The vast majority of the material at Site 1 is non-hazardous debris and household type wastes.
- Waste types include household, commercial, non-hazardous sludge, and industrial waste solids. The IAS reports that liquid wastes were disposed of in trenches at the site.
- Lesser quantities of hazardous wastes are present as compared to municipal wastes. The hotspots at the site represent a very small volume of the total waste.
- Land application units, surface impoundments, injection wells, and waste piles are **not** included. There is no reported history, nor any visual evidence of these at Site 1.

The guidance anticipates that military landfills will have industrial solid waste, paints (and paint thinners), pesticides, transformer oils, and other solvents in relatively low proportion to the volume of municipal wastes – including construction debris, commercial/household type garbage, and yard wastes. The types of waste that would exclude a military site from presumptive remedy consideration include chemical warfare agents, munitions, and other explosives.

Based on the site investigation results, Site 1 has the acceptable characteristics necessary to continue with the presumptive remedy. The following section, *Contaminant Fate and Transport*, will examine the potential impact to local receptors and support refinement of the response action objectives necessary to address the contaminant pathways.

Notes:

Soil Screening Values are equal to TRGs and RSLs for carcinogens, 1/10 the TRGs or RSLs for noncarcinogens

Analytes without established ecological screening values are retained as COPCs for the Screening Level Ecological Risk Assessment

SSL = soil screening level

TRG = target remediation goal

ORNL = Oak Ridge National Laboratory

RSL - Regional Screening Level

COPC = Chemical of Potential Concern

µg/kg = micrograms per kilogram

N = noncarcinogen

mg/kg = milligrams per kilogram

C = carcinogen

USEPA = United States Environmental Protection Agency

NA = not applicable

sat = soil saturation concentration

5.0 CONTAMINANT FATE AND TRANSPORT

The behavior of contaminants released into the environment, particularly the potential for a contaminant to migrate from a release area and persist in an environmental medium, can influence whether the release will result in an adverse human health or ecological effect. The movement of contaminants in the environment will be controlled by certain properties of the contaminant and the availability of suitable pathways for contaminant movement. The fate and transport discussion for this report is limited to the chemicals retained as COPCs as presented in Section 4.0.

5.1 POTENTIAL ROUTES OF MIGRATION

The movement of contaminants in the environment will be controlled by the source and nature and extent of the contaminants and the availability of suitable pathways for contaminant movement.

5.1.1 Potential Contaminant Sources

A review of disposal practices and interviews with site workers during the IAS (Envirodyne, 1985) indicated that during the time this landfill was operated, 1942 to 1948, liquid wastes were buried at the site.

At Site 1, the waste disposal boundary was established by evaluating the results of the geophysical survey. The landfill area as defined by the geophysical survey is approximately 1.5 acres.

The current surface soil cover at Site 1 was emplaced after land filling activities were completed; therefore, surface soil contamination would not be the result of landfill activities unless landfill material was mixed with the soil cover or part of the disposal area was not covered.

5.1.2 Preliminary Site Conceptual Model

The preliminary site conceptual model was developed to evaluate the relationships between the contaminant sources at Site 1, potentially effected media, and contamination migration pathways. Buried waste in the landfill cells was considered the primary source for contaminants at the site. The primary release mechanism is the direct contact of subsurface soil and groundwater with the buried waste, leaching of contaminants to soil and groundwater, and potential migration of liquid wastes disposed of at the site.

Surface soil was considered a secondary source of contaminants because it is fill material of unknown origin emplaced after landfill operations ceased.

5.1.3 Potential Pathways for Contaminant Migration

Based on the evaluation of existing conditions at Site 1, the following potential contaminant transport pathways may exist at the site:

- Leaching of soil contaminants to groundwater.
- Surface migration of soil contaminants to surface water or sediment.
- Migration of groundwater contaminants and discharge to surface water or sediment.
- Volatilization from groundwater and volatilization or particulate migration from surface soil to the atmosphere.

5.1.3.1 Leaching of Soil Contaminants to Groundwater

Contaminants that adhere to soil particles or have accumulated in soil pore spaces can be remobilized and transported to groundwater as a result of infiltration or precipitation. The rate and extent of this leaching are influenced by the following:

- Depth of the water table
- Amount of precipitation
- Rate of infiltration
- Physical and chemical properties of the soil
- Physical and chemical properties of the contaminant

The mobility of chemicals at Site 1 will be influenced by the relatively shallow water table, potentially high rates of precipitation, and sandy soil in the area, which may allow a higher rate of infiltration. The contaminants identified at Site 1 generally have physical and chemical properties that result in low mobility and persistence in the environment.

5.1.3.2 Surface Migration of Soil Contaminants

Contaminants that adhere to soil particles or have accumulated in soil pore spaces can be remobilized and transported mechanically to surface water bodies and associated sediment. The rate and extent of this surface transport are influenced by the following:

- Amount of precipitation
- Physical and chemical properties of the soil

- Physical and chemical properties of the contaminant
- Proximity to receiving waters

The mobility of chemicals at Site 1 could be influenced by the potentially high rates of precipitation and the sandy soil in the area, which may allow mechanical transport. Transport by surface water flow will be inhibited by the grass cover at the site.

5.1.3.3 Migration of Groundwater Contaminants

Contaminants can migrate in a dissolved phase or as an immiscible liquid. A contaminant that is present in water at concentrations greater than its solubility concentration will form an immiscible liquid. Based on the specific gravity of the contaminant, it will either float or sink in the water. In the case of chlorinated solvents (e.g., trichloroethene), the contaminant will sink in the water because it has a higher specific gravity than water. Subsurface transport of immiscible contaminants is governed by a set of factors different from those of dissolved contaminants.

The groundwater data at Site 1 do not provide evidence of immiscible contaminants at concentrations exceeding water solubility levels. For example, VOCs were detected at concentrations less than their water solubilities. Therefore, the migration of groundwater contaminants, for the most part, is likely governed by factors that govern the movement of dissolved contaminants. Three general processes govern the migration of dissolved constituents in groundwater: advection, dispersion, and retardation. Advection is a process by which solutes are carried by groundwater movement. Dispersion is a mixing of contaminated and uncontaminated water during advection. Retardation is a slowing of contaminant migration caused by the reaction of the solute with the aquifer soil.

Contaminant concentrations may be affected by one or more mechanisms during transport. Volatilization or precipitation may physically transform contaminants. Contaminants may be chemically transformed through photolysis, hydrolysis, or oxidation/reduction. Contaminants may also be biologically transformed by biodegradation.

Hydrogeologic data were collected to evaluate movement of groundwater in the shallow surficial aquifer at Site 1. These data were used to estimate the site-specific groundwater flow direction and velocity.

The dissolved contaminants in groundwater may migrate downgradient with the natural flow of groundwater and discharge as seeps to the drainage ditches that run along the eastern side of the site. Contaminants can then migrate in the direction of surface water flow as dissolved constituents in surface water or bound to sediment. Three general processes govern the migration of dissolved contaminants caused by the flow of surface water: movement caused by the flow of surface water, movement caused

by the irregular mixing of water, and chemical mechanisms occurring during the movement of surface water. Sediment particles can disassociate from the sediment into surface water and migrate by one of the aforementioned methods.

At Site 1, contaminants in drainage ditches and swales adjacent to the site may allow transport of contaminants to the north. Storm events are of particular concern because of greater flow velocities, which can mobilize bedload sediments that are usually not disturbed under normal flow conditions. Because most of the site has maintained grass, erosion and overland transport of particulate matter from on-site surface soil do not appear to be important transport mechanisms at Site 1.

5.1.3.4 Volatilization from Soil or Groundwater

Chemicals in soil can migrate into ambient air either as vapors or by adhering to particulate matter (dusts). Chemicals that have a significant volatility are likely to enter ambient air as vapors. Once in groundwater, volatile chemicals may migrate or they may volatilize through the capillary zone and overlying soil layers into ambient air or inside buildings.

Chemicals in the vapor phase may migrate horizontally or vertically and can enter buildings through cracks in the foundation or through foundation walls. Once inside buildings, the air concentrations in buildings are subject to various factors such as building dimensions and ventilation rates. Upon entering ambient air, the vapors are not expected to persist for long periods of time because half-lives of VOCs in the atmosphere are typically measured in hours or a few days. The air concentrations of vapors in ambient air are likely to be quickly diluted by the action of winds. Vapors may also be released directly to ambient air from soil or groundwater during excavation activities.

Many of the contaminants detected in soil and groundwater samples at Site 1 are not especially volatile and are not expected to vaporize into the air. Because most of the site is grass covered, little dust is generated under normal conditions. However, there is a potential for particulate exposure in areas without grass if the soil is heavily disturbed (e.g., during excavation).

5.2 CONTAMINANT PERSISTENCE

The persistence of contaminants after they are released to the environment is controlled by the susceptibility of the contaminants to certain chemical and biological processes that may degrade the contaminants and reduce their remaining mass.

5.2.1 Physical and Chemical Factors Affecting Contaminant Fate

The following properties can be used to evaluate the potential environmental mobility and fate of contaminants:

- Specific gravity
- Vapor pressure
- Water solubility
- Octanol/water partition coefficient (K_{ow})
- Organic carbon partition coefficient (K_{oc})
- Henry's Law constant
- Bioconcentration factor (BCF)
- Mobility index

Table 5-1 presents the physical and chemical properties of the organic compounds detected at Site 1. The relative mobilities of metals as a function of environmental conditions are provided in Table 5-2.

5.2.1.1 Specific Gravity

Specific gravity is the ratio of the weight of a given volume of pure chemical at a specified temperature to the weight of the same volume of water at a given temperature. Specific gravity is used to determine whether a chemical will have a tendency to float or sink in water when present as a pure chemical or at very high concentrations. Non-aqueous-phase chemicals with specific gravities greater than 1 will tend to sink and chemicals with specific gravities less than 1 will tend to float. The groups of chemicals detected at Site 1, particularly chlorinated VOCs, generally have specific gravities greater than 1.

5.2.1.2 Vapor Pressure

Vapor pressure provides an indication of the rate at which a chemical volatilizes from both soil and water. Chemicals with higher vapor pressures are expected to enter the atmosphere much more readily than chemicals with lower vapor pressures. Volatilization is a significant loss process for VOCs in surface water or surface soil and is of primary importance at environmental interfaces such as surface soil/air and surface water/air. Volatilization is not as important when evaluating contaminated groundwater and subsurface soils that are not exposed to the atmosphere. Vapor pressures for halogenated VOCs are typically one or more orders of magnitude higher than vapor pressures for polynuclear aromatic hydrocarbons (PAHs), and volatilization is not significant for metals other than mercury.

5.2.1.3 Water Solubility

The rate at which a chemical may be leached from a solid matrix (e.g., soil or waste deposit) by infiltrating precipitation is proportional to its water solubility. More soluble chemicals are more readily leached than less soluble chemicals. The water solubilities presented in Table 5-1 indicate that trichloroethene is slightly more soluble than PAHs, which are not especially water soluble.

The solubility of inorganics is strongly influenced by their valence state(s) and forms (hydroxides, oxides, carbonates, etc.). The solubility is also dependent on pH, Eh (redox potential), temperature, and other ionic species in solution (the Debye-Huckel theory). The solubility products reported in the literature vary with the type of complex formed, but generally, for example, cadmium and copper complexes are more soluble than lead and nickel complexes.

5.2.1.4 Octanol/Water Partition Coefficient

The K_{ow} is a measure of the equilibrium partitioning of chemicals between octanol and water. A linear relationship between the K_{ow} and the uptake of chemicals by fatty tissues of animal and human receptors (the BCF) has been established. K_{ow} values are also useful in characterizing the sorption of compounds by organic soils where experimental values are not available. PAHs are more likely to partition to fatty tissues than the more soluble VOCs. The K_{ow} is also used to estimate BCFs in aquatic organisms.

5.2.1.5 Organic Carbon Partition Coefficient

The K_{oc} indicates the tendency of a chemical to adhere to soil particles containing organic carbon. Chemicals with high K_{oc} values generally have low water solubilities and vice versa. This parameter may be used to infer the relative rates at which more mobile chemicals (ketones, monocyclic aromatics, and halogenated aliphatics) partition to groundwater. Most PAHs are relatively immobile in soil and are preferentially bound to the soil. These compounds are not as likely to be transported in the dissolved phase by groundwater to the same extent as compounds with higher water solubilities. However, these preferentially bound chemicals are easily transported by erosional processes when they are present in surface soil and the soil particles to which they have adsorbed are mobilized.

5.2.1.6 Henry's Law Constant

Vapor pressure and water solubility are used in determining volatilization rates from surface water bodies and from groundwater. The ratio of these two parameters, the Henry's Law constant, is used to calculate the equilibrium chemical concentrations in the vapor (air) phase versus the liquid (water) phase for the dilute solutions commonly encountered in environmental settings. In general, chemicals having a Henry's Law constant of less than 1×10^{-5} atm-m³ per mole should volatilize very little and be present only in

minute amounts in the atmosphere or soil gas. For chemicals with Henry's Law constants greater than 5×10^{-3} atm-m³ per mole, volatilization and diffusion in soil gas could be significant.

5.2.1.7 Bioconcentration Factor

The BCF represents the ratio of aquatic animal-tissue concentration to water concentration. The ratio is both contaminant and species specific. When site-specific values are not measured, literature values are used or BCFs are derived from K_{ow} values. Many PAHs will bioconcentrate in aquatic animal tissue at levels three to five orders of magnitude greater than those concentrations found in the water in which the organisms reside, whereas trichloroethene does not bioconcentrate to any significant degree.

5.2.1.8 Distribution Coefficient

The distribution coefficient (K_d) is a measure of the equilibrium distribution of a chemical or ion in soil/water systems. The distribution of organic chemicals is a function of both the K_{oc} and the amount of organic carbon in the soil. For an ion (e.g., metal), the K_d is the ratio of the concentration adsorbed on soil surfaces to the concentration in water. K_d values for metals vary over several orders of magnitude because the K_d is dependent on the size and charge of the ion and the soil properties governing exchange sites on soil surfaces. Coulomb's Law predicts that the ion with the smallest hydrated radius and the largest charge will be preferentially accumulated over ions with larger radii and smaller charges.

5.2.1.9 Mobility Index

The mobility index (MI) is a quantitative assessment of chemical mobility in the environment based on the water solubility (S), vapor pressure (VP), and the K_{oc} of a given material (Laskowski et al., 1983) as follows:

$$MI = \log ((S*VP)/K_{oc})$$

The MI for a given chemical is evaluated using the following scale (Ford and Gurba, 1984):

<u>Relative MI</u>	<u>Mobility Description</u>
> 5	extremely mobile
0 to 5	very mobile
-5 to 0	slightly mobile
-10 to -5	immobile
< -10	very immobile

Trichloroethene has a MI close to 5 and is considered very mobile. Pesticides such as BHC have MIs between -5 and -10 and are classified as immobile. Lighter molecular weight PAHs, such as naphthalene, have MIs ranging from -5 to 0 and are considered slightly mobile, and heavier molecular weight PAHs (e.g., benzo(a)pyrene) are classified as very immobile, having MIs less than -10 (Table 5-1).

5.2.2 VOCs

The predominant VOCs detected at Site 1, halogenated aliphatics including tetrachloroethene, trichloroethene, and dichloroethene, are generally volatile at normal temperatures and are typically considered to be fairly soluble in water with a low capacity for retention by soil organic carbon; therefore, these organic compounds are frequently detected in groundwater. The high volatility and water solubility of these chemicals dominate their fate in the environment. These chemicals may migrate through the soil column after being released by a spill event or by subsurface waste burial as infiltrating precipitation solubilizes them. Some fraction of these chemicals is retained by the soil, but most will continue migrating downward to the water table. Upon reaching the water table, migration occurs primarily in the direction of the horizontal hydraulic gradient.

Compounds with specific gravities greater than that of water (e.g., trichloroethene) are often used in various industrial applications such as degreasing. If a large enough spill of these solvents occurs, these chemicals may also migrate as a bulk liquid but will not stop at the water table (i.e., these chemicals will mix with and/or sink into the aquifer).

In general, chlorinated VOCs are subject to abiotic dehydrohalogenation. This process is an elimination reaction that results in the formation of an ethene from a saturated halogenated compound. Research indicates that microbial degradation of highly chlorinated ethanes is a relatively slow process. Chlorinated ethenes are subject to degradation via the action of soil microorganisms. The biodegradation of these compounds in the soil matrix is dependent on the abundance of microflora, nutrient availability, soil reaction (pH), temperature, etc. However, the continued presence of chlorinated VOCs at the site over time suggests that one or more factors are limiting the reductive dechlorination process.

Monocyclic aromatics such as benzene are subject to degradation via the action of both soil and aquatic microorganisms. The biodegradation of these compounds in the soil matrix is dependent on the abundance of microflora, macronutrient availability, soil reaction (pH), temperature, etc. Although these compounds are amenable to microbial degradation, it is not anticipated that degradation will occur at an appreciable rate at Site 1, although macronutrient availability is not known.

Under certain conditions, volatilization is a significant fate process for these compounds. Volatilization is only significant at the air-soil or air-water interface. Compounds may volatilize rapidly to the atmosphere

from soil or surface water due to low soil adsorption. Adsorption is not considered an important fate for these types of compounds when compared to more hydrophobic compounds. BCFs indicate that these compounds should not bioaccumulate.

5.2.3 PAHs

The SVOCs most frequently detected at Site 1 include bis(2-ethylhexyl)phthalate and PAHs. SVOCs as a class of compounds, and PAHs in particular, are considered to be persistent in the environment. SVOCs in soil are much more likely to bind to soil and be transported via mass transport mechanisms than to go into solution. PAHs are subject to degradation via aerobic bacteria but may be relatively persistent in the absence of microbial population or macronutrients such as phosphorus and nitrogen. Land-spreading applications have indicated that PAHs are highly amenable to microbial degradation in soil. The rate of degradation is influenced by temperature, pH, oxygen concentrations, initial chemical concentrations, and moisture. Photolysis, hydrolysis, and oxidation are not important fate processes for the degradation of PAHs in soil.

SVOCs are generally considered to be fairly immobile chemicals in the environment because they are large molecules with high K_{oc} values and low solubilities compared to volatile organics. However, some of the lighter molecular weight PAHs (a subgroup of SVOCs) are more water soluble and environmentally mobile. SVOC compounds in soil generally do not migrate vertically to a great extent and are more likely to adhere to soil particles and be removed from the site via surface runoff and erosional processes.

PAHs are frequently released to the environment through emissions from the incineration of municipal and chemical wastes and in exhaust from internal combustion engines. The PAHs detected at Site 1 may be a by-product of wastes burned at the site.

PAHs generally have very low solubilities, vapor pressures, and Henry's Law constants and high K_{oc} and K_{ow} values. The low molecular weight PAHs (e.g., acenaphthene, anthracene, fluorene, and phenanthrene) may volatilize from surface waters and high molecular weight PAHs (e.g., benzo(a)pyrene, benzo(a)anthracene, chrysene, etc.) are less likely to volatilize.

5.2.4 Pesticides

Pesticides can enter the environment by spraying, dusting, or direct application to soil. Pesticides are expected to have been used as part of maintenance activities at Site 1 and applied per manufacturers' instructions. Many of the compounds detected are no longer licensed for general sale and use in the United States. Pesticides as a class of compounds are not considered to be very mobile in the

environment. These chemicals, upon application or disposal, tend to remain affixed to soil particles. Migration of pesticides generally occurs primarily by erosion via the action of wind or water.

Bioconcentration of pesticides in the food chain is another important fate mechanism. Hydrolysis, oxidation, and photolysis are not generally important fate mechanisms for pesticides in soil or water. Hydrolysis half-lives for several pesticides are reported in periods of months to years. Fate and transport information for some of the more common pesticides detected at Site 1 is summarized as follows:

- **4,4' DDT and its metabolites** are considered to be persistent chemicals. They undergo extensive adsorption to soil and are not highly soluble. Biodegradation may occur under both aerobic and anaerobic conditions in the presence of certain soil microorganisms. Under aerobic conditions, 4,4'-dichlorodiphenyltrichloroethane (DDT) may be transformed to dichlorodipenyldichloroethylene (DDE), and under anaerobic conditions, 4,4'-dichlorodipenyldichloroethane (DDD) may result. These compounds are, however, somewhat volatile, with a reported half-life of 100 days for 4,4'-DDT. These compounds are highly lipophilic and therefore readily bioaccumulate. 4,4'-DDT is no longer in production in the United States.
- **Aldrin** is readily converted to **dieldrin**. Dieldrin is a particularly persistent pesticide but is no longer registered for general use. In soil, dieldrin will persist for long periods of time (more than 7 years) and may slowly evaporate. It does not readily leach to groundwater. Once in surface waters (via runoff), dieldrin adsorbs strongly to sediment and bioconcentrates and slowly photodegrades. Biodegradation and hydrolysis are not significant.
- **Endrin and its metabolites** are no longer produced or used in the United States. These compounds will remain in soil and do not leach significantly, with half-lives of greater than 14 years in sediment. One common transportation and degradation mechanism is photochemical degradation. In water, endrin would not be expected to biodegrade or hydrolyze to any significant extent and therefore will bioconcentrate in aquatic organisms.
- **Chlordane** is extremely persistent in the environment and, in some soils, may persist for greater than 20 years. Volatilization is an important removal mechanism in water and soil. Leaching to groundwater may occur where there are high levels of organic solvents.
- The use of **heptachlor** was restricted to underground termite control in 1983. Heptachlor epoxide is formed by the biological transformation of heptachlor in the environment. These compounds sorb strongly to soil. Heptachlor is subject to biodegradation (forming heptachlor epoxide, which is highly resistant to biodegradation) and hydrolysis. Bioconcentration of both compounds is significant, and volatilization and photolysis are very slow.

PCBs

PCBs were detected only in soil samples at Site 1. Their presence in soil, but not in any aqueous samples, is evidence of their low water solubility and tendency to adhere to particulate matter. PCBs are considered to be very persistent organic chemicals. Biodegradation is the only process known to transform PCBs under environmental conditions, and only the lighter compounds are measurably biodegraded. Although some microorganisms may biodegrade PCBs, such biota may not exist in local soil. There is experimental evidence to suggest that heavier PCBs (five or more chlorines per molecule) can undergo photolytic degradation, but there are no data to suggest that this process operates under environmental conditions. Base-, acid-, and neutral-promoted hydrolysis are considered to be inconsequential degradation mechanisms for PCBs.

5.2.6 Metals

Metals are highly persistent environmental contaminants. They do not biodegrade, photolyze, or hydrolyze. Metals released to the environment generally adsorb to the soil matrix (compared to being part of the soil structure) and bioaccumulate. Because metals are frequently incorporated into the soil matrix and remain bound to particulate matter, they migrate from source areas via bulk movement processes (erosion).

The mobility of metals is influenced primarily by their physical and chemical properties, in combination with the physical and chemical characteristics of the soil matrix. Factors that assist in predicting the mobility of inorganic species are the soil/pore water pH, soil/pore water oxidation reduction potential (Eh) of groundwater, and cation exchange capacity. The mobility of metals generally increases with decreasing soil pH and cation exchange capacity (Table 5-2). Metals are more mobile under acidic conditions. In these cases, it is possible for metals to migrate vertically through the soil column and reach the groundwater.

The detected concentrations of arsenic in environmental media at Site 1 may be attributed to naturally occurring conditions. Pettry and Switzer (2001) evaluated arsenic concentrations in soil in Mississippi and reported data from five sample locations in the Coastal Flatwoods in Jackson County and one in Hancock County. The reported concentrations of arsenic in the Coastal Flatwoods samples ranged from 0.38 to 4.78 mg/kg. The arsenic levels reported at Site 1 were in the lower range of the background concentrations in the area.

5.3 CONTAMINANT MIGRATION

Transport of contaminants after they are released to the environment is controlled by the following:

- Nature and extent of contamination
- Physical properties of the contaminants
- Potential migration pathways

These factors determine whether the contaminant partitions to more mobile media (air or groundwater) or less mobile media (soil or sediment particles).

5.3.1 Site Conceptual Model

The primary release mechanism is the direct contact of subsurface soil and groundwater with the buried waste, leaching of contaminants to soil and groundwater, and potential migration of liquid wastes disposed of at the site.

Surface soil was considered a secondary source of contaminants because it is fill material of unknown origin emplaced after landfill operations had ceased and may also have been affected by site activities not related to the landfill operation.

The potential pathways for contaminant migration at Site 1 are shown in Table 5-3.

5.3.2 Surface Soil/Subsurface Soil/Groundwater Pathway

The potential for contaminants to leach from surface soil to subsurface soil and groundwater is evaluated because contaminants were reported in Site 1 soil at concentrations greater than default leaching criteria. The COPCs detected in each of these media are compared in Table 5-4 and summarized as follows:

- VOCs – 2-butanone was reported infrequently in each of the media in this pathway. The 2-butanone concentrations in surface and subsurface soil were comparable. The concentrations in groundwater were less than the screening criteria.
- SVOCs- benzo(b)fluoranthene and caprolactam were the only SVOCs detected in surface soil, but were not reported in subsurface soil or groundwater samples. Naphthalene was detected in one monitoring well sample, but not in any soil samples.

- Pesticides – Endrin aldehyde was reported infrequently in each of the media in this pathway, although this chemical was retained as a COPC only for surface soil. Aldrin, BHC isomers, dieldrin, and heptachlor epoxide were detected in surface soil samples at concentrations greater than the leaching SSLs. These same pesticides, excluding aldrin, were also detected in subsurface soil samples at concentrations greater than the leaching SSLs. None of these pesticides were reported in the groundwater samples.
- PCBs – Aroclor 1260 was reported in one surface soil sample and none of the other media in this pathway. Aroclor 1242 was reported only in one subsurface soil sample.
- Metals – A number of metals were frequently detected in the media sampled at Site 1. Antimony, arsenic, chromium, cobalt, copper, iron, lead, manganese, and selenium were detected in one or more surface soil samples at concentrations greater than the SSLs for the soil leaching pathway. Only arsenic, chromium, and iron were detected in subsurface soil samples at concentrations greater than the SSLs. Aluminum, arsenic, iron, manganese, and thallium were detected in groundwater samples at concentrations exceeding screening criteria.

5.3.3 Surface Soil/Surface Water/Sediment Pathway

Because contaminants were detected in surface soil samples at concentrations exceeding screening criteria, the surface soil-to-sediment and surface water pathways are evaluated. The site was capped with fill material of unknown origin at some time after landfill operations ceased. Routine maintenance activities, which may have included pesticide applications, have been conducted in the subsequent years. The analytes detected in each of these media are compared in Table 5-5 and summarized as follows:

- VOCs – 2-butanone was detected in surface soil and sediment samples. The 2-butanone concentrations in the sediments were up to an order of magnitude greater than the concentrations reported in surface soil, suggesting that sources other than Site 1 are contributing to the 2-butanone in sediments. Acetone and toluene were identified as COPCs for sediment and/or surface water. These analytes were not reported in surface soil samples from Site 1, indicating that this migration pathway was not complete.
- SVOCs- benzo(b)fluoranthene and caprolactam were the only SVOC COPCs detected in surface soil. Diethyl phthalate, while not a surface soil COPC, was detected in three of the sediment samples. The diethyl phthalate concentrations in the sediments were up to an order of magnitude greater than the concentrations reported in surface soil, suggesting that sources other than Site 1 are contributing to the diethyl phthalate in sediments.

- PCBs – Aroclor 1260 was reported in one surface soil sample and none of the other media in this pathway.
- Metals – A number of metals were frequently detected in the media sampled at Site 1. Antimony, arsenic, chromium, cobalt, copper, iron, lead, manganese, and selenium were detected in one or more surface soil samples at concentrations greater than screening criteria. Only arsenic, chromium, iron, lead, and manganese were retained as COPCs for surface water and sediment.

5.3.4 Groundwater/Surface Water/Sediment Pathway

The east and west ditches may receive groundwater discharge from Site 1. Therefore, the groundwater-to-surface water and sediment pathways are evaluated. The analytes detected in each of these media are compared in Table 5-6 and summarized as follows:

- VOCs – 2-butanone was detected in groundwater and sediment samples. 2-butanone was reported more frequently and at higher concentrations in the sediment samples suggesting that sources other than Site 1 are contributing to the 2-butanone in sediments. Acetone was reported in each of the media in this pathway. Acetone concentrations in groundwater and surface water were comparable. Carbon disulfide, while not a groundwater COPC, was detected in two of the surface water samples. The carbon disulfide concentrations in the surface water were up to an order of magnitude less than the concentrations reported in groundwater. Toluene was identified as a COPC for sediment and surface water. Toluene was not reported in groundwater samples from Site 1, indicating that this migration pathway was not complete.
- SVOCs- Bis(2-ethylhexyl)phthalate was detected in groundwater and sediment samples. The concentrations in the sediments were greater than the concentrations reported in groundwater, suggesting that sources other than Site 1 are contributing to the 2-butanone in sediments.
- Pesticides –The pesticide that was detected in groundwater at Site 1, Endrin aldehyde, was not detected in surface water or sediment samples.

5.3.5 Soil and Groundwater to Air Pathway

To determine the potential for migration of soil or groundwater contaminants to the atmosphere, contaminant concentrations in these media were compared to USEPA SSLs (surface and subsurface soil) and USEPA groundwater volatilization criteria. Table 5-7 compares the analytes detected in each of these media. SSLs have been established for various volatiles, pesticides/PCBs, and metals. Concentrations of these classes of analytes detected in soil at Site 1 were less than the default SSLs.

Surface soil- and subsurface soil-to-air and inhalation pathways are not considered complete because concentrations of contaminants detected in soil were less than the default SSLs.

USEPA groundwater volatilization criteria have been established for many of the VOCs detected in groundwater at Site 1. Tetrachloroethene and trichloroethene were detected in one or more groundwater samples at concentrations greater than the default criteria, indicating the potential for migration and accumulation of vapors from groundwater. Further evaluation of these COPCs is included in the HHRA.

6.0 HUMAN HEALTH RISK ASSESSMENT

This baseline HHRA was performed to characterize and quantify potential health risks at Site 1, Disaster Recovery Disposal Area at the NCBC Gulfport. The objective of the risk assessment is to determine whether detected concentrations of chemicals within the study areas pose a significant threat to potential human receptors under current and/or future land use. The risk assessment for Site 1 is based on chemical data for surface soil, subsurface soil, groundwater, surface water, and sediment collected between March and October of 2008. The potential risks to human receptors are estimated based on the assumption that no actions are taken to control contaminant releases. The baseline risk assessment consists of five major components:

- Data evaluation and identification of COPCs
- Identification of significant exposure pathways
- Toxicity assessment
- Estimation of potential human health risks
- Characterization of uncertainty in the risk assessment

Section 6.1 lists USEPA and MDEQ guidance used to prepare the baseline HHRA. Section 6.2 describes the methods used to evaluate data usability for the risk assessment. Methods for selecting COPCs to be evaluated quantitatively in the risk assessment are described in Section 6.3. COPCs are selected to represent those compounds likely to have the highest potential health risk, based on chemical concentration, toxicity, and mobility. The COPC screening process involves comparing maximum site concentrations to risk-based screening levels.

Section 6.4 presents an overview of the Exposure Assessment, which characterizes potential receptor populations and the pathways by which they may come into contact with contaminants at the site. Discussions of current and future land uses, potential human receptors, exposure scenarios, and methods used to estimate chemical intakes are included. In addition, specific exposure parameters used to calculate chemical intakes are presented. The chemical intake estimates are based on chemical concentrations at receptor locations, human activity patterns, physiological factors, and exposure duration and frequency. Current and reasonable future exposure scenarios are developed on the basis of site characteristics, land use and zoning plans, human activity patterns, potential chemical migration pathways, and other pertinent information.

Section 6.5 presents an overview of the Toxicity Assessment and the chemical-specific toxicity criteria used in quantifying potential human health risks. When integrated with chemical intake estimates developed in the Exposure Assessment, these toxicity factors provide a basis for quantifying potential human health risks.

Methods used for characterizing risks associated with noncarcinogenic and carcinogenic effects for exposure to COPCs are presented in Section 6.6.

The quantitative risk estimates are based on a number of assumptions about exposure and toxicity. Thus, the risk estimates may over- or underestimate the level of potential human health risks associated with a site. The Uncertainty Analysis (Section 6.7) describes in qualitative and semi-quantitative terms the sources of uncertainty in the risk assessment. Section 6.8 presents the summary and conclusions of the risk assessment.

6.1 RISK ASSESSMENT GUIDANCE

The following guidance was used to prepare the HHRA:

- Risk Assessment Guidance for Superfund (RAGS), Volume I. Human Health Evaluation Manual, Part A. Interim Final (USEPA, 1989).
- RAGS, Volume I. Human Health Evaluation Manual: Standard Default Exposure Factors (USEPA, 1991b).
- Selecting Exposure Routes and Contaminants of Concern by Risk-Based Screening. Region 3 Technical Guidance Manual Risk Assessment (USEPA, 1993b).
- Distribution of Preliminary Review Draft: "Superfund's Standard Default Exposure Factors for the Central Tendency and Reasonable Maximum Exposure" (USEPA, 1993d).
- Soil Screening Guidance: Technical Background Document (USEPA, 1996b).
- Exposure Factors Handbook (USEPA, 1997c).
- RAGS, Human Health Evaluation Manual, Part D: "Standardized Planning, Reporting, and Review of Superfund Risk Assessments" (RAGS Part D) (USEPA, 2001d).
- Risk Evaluation Procedures for Voluntary Cleanup and Development of Brownfield Sites, MDEQ (MDEQ, 2002a).
- Supplemental Guidance For Developing Soil Screening Levels For Superfund Sites, OSWER 9355.4-24, Office of Solid Waste and Emergency Response Washington, D.C. (USEPA, 2002b).
- Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous OSWER 9285.6-10. Waste Sites. Office of Emergency and Remedial Response, Washington, D.C., (USEPA, 2002c).
- Work Plan for RI at Site 1 – Disaster Recovery Disposal Area, NCBC, Gulfport, Mississippi (TTNUS, 2009).

- RAGS: Volume I, Human Health Evaluation Manual, Part E, Supplemental Guidance for Dermal Risk Assessment) Interim Guidance (USEPA, 2004c).
- Guidelines for Carcinogen Risk Assessment (USEPA, 2005e).
- Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, March 2005c).
- RAGS: Volume I, Human Health Evaluation Manual, Part F, Supplemental Guidance for Inhalation Risk Assessment (USEPA, 2009).

In addition, USEPA's online database, Integrated Risk Information System (IRIS) (USEPA, online, April 2009), was used to identify the most recently published toxicity criteria for the identified COPCs.

6.2 DATA EVALUATION

Information associated with data usability of the data collected at Site 1 is provided in this section.

The HHRA presented in this report is based on the most recent analytical data collected at Site 1 (the data were collected by TtNUS between March and October 2008). Historical soil, groundwater, surface water, and sediment data were not used in the quantitative risk assessment. A summary of the analytical data from these investigations is presented in Section 3.1 of the Work Plan for the RI at Site 1 (TtNUS, January 2009).

Fixed-base laboratory analytical results for target analytes from the field investigation were used in the quantitative risk evaluation. Unfiltered results for groundwater and surface water are used to assess risks associated with these media. Field measurements and data regarded as unreliable (i.e., qualified as "R" during the data validation process) were not used in the quantitative risk assessment. Analytical data qualified as estimated ("J", or "UJ") were used, even though the reported positive concentrations or sample-specific quantitation limits may be somewhat imprecise. The use of estimated data adds to the uncertainty associated with the risk assessment; however, the associated uncertainty is expected to be negligible compared with the other uncertainties inherent in the risk evaluation process (i.e., uncertainties with land uses, exposure scenarios, toxicological criteria, etc.). Analytical data qualified for blank contamination were used in the baseline risk assessment. When determining exposure concentrations via statistical procedures, analytical results qualified because of blank contamination and non-detected results were conservatively assumed to be present at concentrations equal to one-half the sample-specific quantitation limit.

All analytical data used in the quantitative estimation of potential risks were validated.

6.3 SELECTION OF CHEMICALS OF POTENTIAL CONCERN

The selection of COPCs is a qualitative screening process used to limit the number of chemicals and exposure routes quantitatively evaluated in the HHRA to those site-related constituents that dominate overall potential risks. Screening of site data against risk-based concentrations (RBCs) is used to focus the risk assessment on meaningful chemicals and exposure routes.

In general, a chemical is selected as a COPC and retained for further quantitative risk evaluation in the HHRA if the maximum detection in a sampled medium exceeds a conservative screening value(s) and the chemical is determined to be present at concentrations exceeding background levels, if available. Chemicals eliminated from further evaluation at this time are assumed to present minimal risks to potential human receptors.

6.3.1 Derivation of Screening Criteria

Screening concentrations based on the ORNL RSLs, MDEQ TRGs, and USEPA MCLs were used to select COPCs for Site 1. The risk-based screening concentrations (i.e., those based on the ORNL RSLs and MDEQ TRGs) correspond to a systemic HQ of 0.1 (for noncarcinogens) or a lifetime cancer risk of 1×10^{-6} (for carcinogens). Note that the ORNL RSLs and the MDEQ TRGs are based on a HQ of 1.0 and the screening concentrations are based on a HQ of 0.1. This is because the screening levels for non-carcinogenic chemicals have been divided by a factor of 10 to further account for the potential cumulative effects of several chemicals affecting the same target organ or producing the same adverse noncarcinogenic health effect.

Screening levels based on the following standards/criteria were used to select COPCs for soil:

- ORNL RSLs for Residential Soil (ORNL, 2009).
- MDEQ Tier 1 TRGs for restricted and unrestricted land use (MDEQ, 2002b).
- USEPA generic SSLs for the inhalation of volatiles and fugitive dusts calculated online at http://risk.lsd.ornl.gov/calc_start.shtml based on methodology from the USEPA's Soil Screening Guidance (USEPA, 1996b).

Screening levels based on the following criteria were used to select COPCs for sediment:

- ORNL RSLs for Residential Soil (ORNL, 2009).
- MDEQ Tier 1 TRGs for restricted and unrestricted land use (MDEQ, 2002b)

Screening levels based on the following criteria were used to select COPCs for groundwater:

- ORNL RSLs for Tap water (ORNL, 2009).
- MDEQ Tier 1 TRGs for Groundwater (MDEQ, 2002b)
- USEPA MCLs (USEPA, August 2006)

Screening levels based on the following criteria were used to select COPCs for surface water:

- ORNL RSLs for Tap water (ORNL, 2009).
- MDEQ Tier 1 TRGs for Groundwater (MDEQ, 2002b)

If the maximum concentration of a constituent exceeded any of these criteria, then the chemical was selected as a COPC and carried through the quantitative risk assessment.

Soil data were also compared to ORNL SSLs for migration from soil to groundwater (ORNL, 2009). The soil-to-groundwater SSLs were not used to select COPCs for quantitative risk evaluation but to provide an evaluation of potential impact of chemicals detected in soil on groundwater. Exceedances of the soil-to-groundwater SSLs are discussed in Section 6.3.2.

Lead as a COPC

Limited criteria are available to evaluate the potential risks associated with lead. There are no RBCs for this chemical because USEPA has not developed toxicity values [i.e., Cancer Slope Factors (CSFs), Reference Doses (RfDs)] for lead. However, recommended screening levels are available for lead in soil that are used to indicate the need for response activities.

Guidance from both the Office of Prevention, Pesticides, and Toxic Substances (OPPTS) and the Office of Solid Waste and Emergency Response (OSWER) recommend 400 mg/kg as the lowest screening level for lead-contaminated soil in a residential setting where children are frequently present (USEPA, July 1994b). OPPTS identifies 2,000 to 5,000 mg/kg as an appropriate range for areas where contact with soil by children in a residential setting is less frequent. A value of 400 mg/kg was used as the screening level for soil and sediment in the HHRA for Site 1.

The Safe Drinking Water Act (SDWA) Action Level (15 µg/L) was used as the screening level for lead in groundwater and surface water.

Essential Nutrients and Chemicals without Toxicity Criteria

The essential nutrients calcium, magnesium, potassium, and sodium were not identified as COPCs because these inorganic chemicals are naturally abundant in environmental matrices and are only toxic at

high doses. In addition, because of the lack of toxicity criteria, risk-based COPC screening levels are not available for some chemicals (i.e., phenanthrene, alpha- and gamma-chlordane, delta-BHC, endosulfan II, endosulfan sulfate, and endrin aldehyde). Appropriate surrogates were selected for some of these chemicals based on similar chemical structures. Pyrene was used as the surrogate for phenanthrene, chlordane was used as a surrogate for alpha- and gamma-chlordane, alpha-BHC was used as a surrogate for delta-BHC, endosulfan was used as a surrogate for endosulfan II and endosulfan sulfate, and endrin was used as a surrogate for endrin aldehyde.

Determination of Site-Related Chemicals (Background Evaluation)

No background sample data are available for soil, sediment, or surface water at NCBC Gulfport. Therefore, a background screen (i.e., a comparison of site-data to background data) was not used in the selection of COPCs for these media. One monitoring well sample and four DPT samples (plus one duplicate) were used as background data for COPC selection in the monitoring well and DPT groundwater datasets, respectively. A comparison of the maximum detected concentrations in both site and background datasets was conducted. Ideally, chemicals exceeding the risk-based screening levels but below site background concentrations would not be selected as COPCs. However, no chemicals were eliminated from COPC selection on the basis of background for Site 1.

A discussion of the chemicals identified as COPCs and the rationale for their selection are provided in the following sections.

6.3.2 COPC Selection for Surface Soil

This section presents the results of the COPC selection process for surface soil. Table 6-1 shows the results of the comparison of the maximum detected surface soil concentrations to screening levels based on the ORNL RSLs and MDEQ TRGs. The following chemicals were retained as COPCs for surface soil:

- One pesticide (dieldrin)
- Inorganics (aluminum, antimony, arsenic, cobalt, iron, manganese)

These constituents were identified as COPCs in surface soil because maximum concentrations exceeded one or more of the screening criteria. The maximum concentration for cobalt exceeded the ORNL residential soil criterion only. The maximum detected concentrations of aluminum, antimony, iron, and manganese exceeded the ORNL residential soil criteria and MDEQ Tier 1 TRGs for unrestricted land use but did not exceed the MDEQ Tier 1 TRGs for restricted land use. Both dieldrin and arsenic exceeded the ORNL residential criteria and both unrestricted and restricted MDEQ TRGs. The only organic compound selected as a COPC, dieldrin, was detected in 8 of 20 samples. Antimony was detected in only 2 of 21 samples, arsenic was detected in 19 of 21 samples, and cobalt was detected in only 1 of

21 samples. Aluminum, iron, and manganese were detected in all 21 surface soil samples. No site-specific background data are available for NCBC Gulfport for these chemicals. Therefore, a background screen was not used in the COPC selection process for surface soil. Note that the maximum concentrations for aluminum, antimony, cobalt, iron, and manganese did not exceed the associated MDEQ unrestricted and ORNL residential soil criteria if a noncancer benchmark of HI = 1 (i.e., the published screening level) were used instead of an hazard index (HI) = 0.1.

Although no site-specific background data were available for surface soil, the maximum concentrations of all inorganic COPCs for surface soil are well within naturally occurring background levels found in U.S. soil (Dragun, 1988). Additionally, the maximum concentration of arsenic (4.8 mg/kg), was within the range of background concentrations detected in the state of Mississippi (0.26 – 24.43 mg/kg) as determined in a study of arsenic in Mississippi soils performed by Mississippi State University in 2001 (Pettry and Switzer, 2001). Therefore, based on the scientific literature consulted, the concentrations of aluminum, antimony, arsenic, cobalt, iron, and manganese in surface soil at Site 1 may reflect background conditions..

The maximum concentrations of all chemicals detected in surface soil were also compared to USEPA Generic SSLs for migration from soil to air (inhalation), when available. As shown in Table 6-1, the maximum concentrations of all constituents were less than the inhalation SSLs. Therefore, potential risks from inhalation of chemicals detected in surface soil are expected to be minimal and this pathway is not evaluated further in the risk assessment.

Migration of Chemicals from Surface Soil to Groundwater

In Table 6-2, maximum concentrations in surface soil were also compared to the USEPA SSLs for the groundwater protection calculated using a dilution/attenuation factor of 1 (DAF = 1) (ORNL, 2009). The following chemicals were detected in the surface soils at maximum concentrations exceeding the COPC screening levels for contaminant migration from soil to groundwater:

- One volatile (tetrachloroethene)
- One semivolatile (benzo(b)fluoranthene)
- Pesticides/PCBs (aldrin, alpha-BHC, Aroclor-1260, beta-BHC, delta-BHC, dieldrin, heptachlor epoxide)
- Inorganics (antimony, arsenic, chromium, cobalt, copper, iron, lead, manganese, selenium)

These exceedances of the SSLs may indicate the potential for chemicals in soil to leach to groundwater and impact water quality. However, of the chemicals that exceeded the migration-to-groundwater SSLs,

only tetrachloroethene, aluminum, arsenic, chromium, iron, lead, and manganese were detected in groundwater samples collected at the site.

Tetrachloroethene was the only organic COPC selected for the migration to groundwater pathway that was also detected in site groundwater. This chlorinated volatile organic chemical was detected in only 2 of 21 surface soil samples, in 3 of 25 DPT groundwater samples, and in none of the monitoring well groundwater samples (although tetrachloroethene was detected in the background sample for the monitoring well data set). The soil data for organic chemicals suggests that the surface soils are not a significant residual contaminant source for groundwater contamination at Site 1. Further evidence of this is the fact that of the chlorinated VOCs detected in both the monitoring well and DPT samples (i.e., acetone, carbon disulfide, trichloroethene) and in the DPT samples alone (i.e., 2-butanone, chloromethane, cis-1,2-dichloroethene, tetrachloroethene), only 2-butanone and tetrachloroethene were detected in surface soil. Note that neither 2-butanone nor tetrachloroethene was detected in any monitoring well samples (although tetrachloroethene was detected in the monitoring well background sample).

All metals exceeding the migration from soil-to-groundwater SSLs except for antimony, cobalt, copper, and selenium were detected in groundwater samples. The maximum concentrations of all migration to groundwater COPCs for surface soils except for copper were within the range of soil background levels reported in the continental U.S. (Dragun, 1988). The maximum concentration of copper was within one order of magnitude of the upper limit for the typical range of soil concentrations and well within the extreme limits range reported for this element in native soil. Of the migration COPCs detected in site groundwater samples, arsenic, iron, and manganese were the only COPCs detected in groundwater. The maximum arsenic concentration exceeds the associated MCL, and the maximum iron and manganese concentrations exceed the associated secondary MCLs. However, as mentioned previously, soil concentrations of arsenic and manganese are within published background levels. The maximum concentration of iron in groundwater was also within published background levels (see Section 6.3.4). The available data indicate that groundwater quality at Site 1 has not been adversely impacted by the migration of metals from soil to groundwater.

An additional consideration is the fact that the SSLs (DAF = 1) are very conservative because a DAF of 1 assumes that no dilution or attenuation occurs as a chemical migrates from soil to groundwater. The USEPA in the Soil Screening Guidance (USEPA, 1996b) recommends that a DAF of 20 be used as the default DAF and states that "A DAF of 20 is protective for sources up to 0.5 acre in size". Further analyses presented in the SSL guidance indicate that it can be protective of larger sources as well. If SSLs for a DAF of 20 were calculated from the ORNL values presented in Table 6-2 (i.e., the ORNL SSLs were multiplied by a factor of 20), only the maximum concentrations of dieldrin, heptachlor epoxide, and

arsenic would exceed their respective SSLs. However, as discussed previously, the maximum concentration of arsenic detected in surface soil may be due to naturally occurring background levels.

6.3.3 COPC Selection for Subsurface Soil

This section presents the results of the COPC selection process for subsurface soil. The COPC screening process for subsurface soil and the results of the screening are presented in Table 6-3. The subsurface soil data set consists of 17 samples (and 2 duplicates) collected in May and October of 2008. The following chemicals were retained as COPCs for subsurface soil:

- One PCB (Aroclor-1242)
- Inorganics (aluminum, arsenic)

These constituents were identified as COPCs in subsurface soil because maximum concentrations exceeded one or more of the human health risk screening levels for residential land use (i.e., ORNL risk-based screening levels for residential soil and/or MDEQ Tier 1 TRGs for restricted and unrestricted land use). The maximum detected concentrations of Aroclor-1242, aluminum, and arsenic exceeded the ORNL residential soil RSLs and MDEQ Tier 1 TRGs for unrestricted land use but did not exceed the MDEQ Tier 1 TRGs for restricted land use. No site-specific background data are available for NCBC Gulfport for these chemicals. Therefore, a background screen was not used in the COPC selection process. The maximum concentration of Aroclor-1242 (2.4 mg/kg) is within one order of magnitude of the Toxic Substances Control Act soil cleanup level of 1 mg/kg, which applies to high occupancy areas (USEPA, November 2005). Additionally, Aroclor-1242 was detected in only one of seven samples. The maximum concentration of arsenic is well within naturally occurring background levels, and the maximum concentration of aluminum is slightly less than the lower limit for the typical range of background levels found in U.S. soil (Dragun, 1988). In addition, the maximum concentration of arsenic (2 mg/kg) is within the range of background concentrations determined in a study of arsenic in Mississippi soils (Pettry and Switzer, 2001). Based on a comparison of site data to the available background data presented in the scientific literature, the concentrations of aluminum and arsenic detected in subsurface soil at Site 1 may reflect background conditions.

The maximum concentrations were also compared to USEPA Generic SSLs for migration from soil to air (inhalation), when available. As shown in Table 6-3, the maximum concentrations of all constituents were less than the inhalation SSLs. Therefore, potential risks from inhalation of chemicals detected in soil are expected to be minimal and this pathway is not evaluated further in the risk assessment.

Migration of Chemicals from Subsurface Soil to Groundwater

In Table 6-4, maximum concentrations in subsurface soil were also compared to the ORNL SSLs for the groundwater projection calculated using a dilution/attenuation factor of 1 (DAF = 1) (ORNL, 2009). The following chemicals were detected in the subsurface soils at maximum concentrations exceeding the COPC screening levels for contaminant migration from soil to groundwater:

- One volatile (chloromethane)
- Pesticides/PCBs (alpha-BHC, Aroclor-1242, beta-BHC, delta-BHC, dieldrin, heptachlor epoxide)
- Inorganics (arsenic, chromium, iron)

These exceedances of the SSLs may indicate the potential for chemicals in soil to leach to groundwater and impact water quality. However, of the organic chemicals that exceeded the migration-to-groundwater SSLs, only chloromethane was detected in any site groundwater samples. Chloromethane was detected in 1 of 25 DPT groundwater samples only (and was not detected in any monitoring well samples). Additionally, chloromethane was only detected in 1 of 13 subsurface soil samples. Alpha-BHC was detected in 1 of 3 subsurface soil samples, and Aroclor-1242 was detected in 1 of 7 samples. Beta-BHC, delta-BHC, dieldrin and heptachlor epoxide have detection frequencies of 2/2, 1/3, 1/2, and 2/3, respectively. The soil data for organic chemicals suggests that the subsurface soils are not a significant residual contaminant source for groundwater contamination at Site 1. Further evidence of this is the fact that of the chlorinated VOCs detected in both the monitoring well and DPT samples (i.e., acetone, carbon disulfide, trichloroethene) and in the DPT samples alone (i.e., 2-butanone, chloromethane, cis-1,2-dichloroethene, tetrachloroethene), only carbon disulfide, 2-butanone, and chloromethane were detected in subsurface soil. Note that neither 2-butanone nor chloromethane was detected in any monitoring well samples; however, tetrachloroethene was detected in the monitoring well background sample.

All of the metals exceeding the migration from soil-to-groundwater SSLs were detected in groundwater samples. The maximum arsenic concentration exceeds the associated MCL, and the maximum iron concentration exceeds the associated secondary MCL. However, the maximum concentration of chromium does not exceed the associated MCL. The maximum concentrations of arsenic and chromium in subsurface soil are within the typical range of naturally occurring background levels, and the maximum concentration of iron is well below the lower limit for the typical range of naturally occurring background concentrations (Dragun, 1988). Of the inorganic migration to groundwater COPCs, arsenic and iron are also groundwater COPCs (chromium is not). However, the maximum concentration of arsenic in subsurface soil is less than/within typical U.S. background levels (as mentioned above), and arsenic and iron concentrations in groundwater are within U.S. background levels (see Section 6.3.4). The available

data indicate that groundwater quality at Site 1 has not been adversely impacted by the migration of metals from soil to groundwater.

An additional factor to consider is the fact that the SSLs (DAF=1) are very conservative because a DAF of 1 assumes that no dilution or attenuation occurs as a chemical migrates from soil to groundwater. The USEPA in the Soil Screening Guidance (USEPA, 1996b) recommends that a DAF of 20 be used as the default DAF and states that "A DAF of 20 is protective for sources up to 0.5 acre in size". Further analyses presented in the SSL Guidance indicate that a DAF of 20 can be protective of larger sources as well. If SSLs for a DAF of 20 were used in the comparisons presented in Table 6-4 (i.e., if the ORNL SSLs were multiplied by a factor of 20), chloromethane, dieldrin, chromium, and iron would not be selected as COPCs. As previously discussed, the concentrations of the metals detected in subsurface soil may be due to naturally occurring background concentrations.

6.3.4 COPC Selection for Groundwater

A comparison of the maximum detected DPT and monitoring well groundwater concentrations to screening levels based on the ORNL RSLs for tap water, MDEQ TRGs for groundwater, and USEPA MCLs is presented in Tables 6-5 and 6-6, respectively. The following chemicals were retained as COPCs for groundwater:

DPT samples:

- One volatile (tetrachloroethene)

Monitoring well samples:

- One semivolatile (naphthalene)
- Inorganics (aluminum, arsenic, iron, manganese, thallium)

For the DPT samples, the only COPC, tetrachloroethene, exceeded the ORNL RSL for tap water; the MDEQ groundwater TRG and the USEPA MCL were not exceeded. For the monitoring well samples, all COPCs except for naphthalene and arsenic exceeded the ORNL tap water RSLs, the USEPA MCLs or SMCLs, and the MDEQ TRGs. Naphthalene exceeded both the ORNL RSL and the MDEQ groundwater TRG; however, no MCL is available for naphthalene. Arsenic exceeded the ORNL tap water RSL only and was detected in only 2 of 21 groundwater samples.

Tetrachloroethene was detected in only 3 of 25 DPT groundwater samples and was not detected in any monitoring well samples. However, tetrachloroethene was also detected at a concentration of 2.5 ug/L in sample 01GW2301 from location GPT-01-23. Location GPT-01-23 was designated as upgradient and used as a background location. Naphthalene and arsenic were only detected in 1/21 and 2/21 samples, respectively. The remaining COPCs, aluminum, iron, and manganese, were detected in all (21/21) samples. High sample turbidity (>10 Nephelometric Turbidity Units) was reported for 4 of the 22 monitoring well locations (including the background location). However, no maximum concentrations of metals were reported from the wells with high turbidity. The maximum concentrations of arsenic (19.1 ug/L), iron (44,000 ug/L) and manganese (548 ug/L) are well within the typical background ranges reported in Dragun, 1988 (typical background range for arsenic is < 1.0 – 30 ug/L; typical background range for iron is 10 – 10,000 ug/L; typical background range for manganese is < 1.0 – 1000 ug/L). Aluminum (maximum concentration = 6320 ug/L) exceeded the upper limit of the typical groundwater background range published in Dragun, 1988 (upper limit: 1000 ug/L); however, the maximum concentration of aluminum was within one order of magnitude of the aforementioned upper limit.

Vapor Intrusion Pathway from Groundwater to Soils

Vapor Intrusion is the migration of volatile chemicals from the subsurface into overlying buildings. Volatile chemicals in buried wastes, soils, and/or contaminated groundwater can emit vapors which may migrate from subsurface strata and into indoor air spaces of overlying or adjoining buildings (USEPA, 2002a). Because volatile organic chemicals were detected in groundwater samples at Site 1, COPCs for groundwater were also selected based on a comparison of maximum detected concentrations to EPA screening designed to conservatively evaluate the potential for vapor intrusion into a building. The results of the comparison of maximum concentrations in groundwater to the USEPA Groundwater Volatilization Criteria are presented in Table 6-7 (DPT samples) and in Table 6-8 (monitoring well samples). The following chemical was detected in the groundwater at maximum concentrations exceeding the COPC screening levels for vapor intrusion from groundwater to soils and was retained as a COPC:

DPT samples:

- One volatile (trichloroethene)

Monitoring well samples:

- One volatile (trichloroethene)

Trichloroethene was selected as a COPC for the vapor intrusion pathway in both the DPT and the monitoring well groundwater samples. It should be noted that the maximum concentrations of

trichloroethene were less than the maximum background concentrations from the upgradient locations in both the DPT and monitoring well datasets. In addition, trichloroethene was only detected in 1 of 25 DPT samples and 1 of 21 monitoring well samples. However, conservatively, trichloroethene was retained as a COPC for the vapor intrusion pathway.

6.3.5 COPC Selection for Surface Water

A comparison of the maximum detected surface water concentrations to screening levels based on the ORNL RSLs for tap water and MDEQ TRGs for groundwater is presented in Table 6-9. The following chemicals were retained as COPCs for surface water:

- Inorganics (arsenic, iron)

These constituents exceeded the ORNL RSLs and MDEQ Tier 1 TRGs for groundwater. Note that the use of these criteria for surface water assumes that the surface water is used as a drinking source (i.e., potential receptors ingest 2 liters of water per day for 350 days per year). Groundwater criteria are used because surface water criteria for human health are currently not available. Using these criteria is extremely conservative because groundwater criteria assume that the water is a potential drinking source. However, it is unlikely that the water in Canal No. 1 downgradient of the site would ever be used as a source of drinking water.

6.3.6 COPC Selection for Sediment

This section presents the results of the COPC selection process for sediment. Table 6-10 shows the results for the comparison of the maximum detected sediment concentrations to screening levels based on the ORNL residential soil RSLs and MDEQ TRGs and summarizes the COPC selection process for sediment at Site 1. The following chemicals were retained as COPCs for sediment:

- Semivolatiles (Benzo(a)pyrene equivalents)
- Inorganics (aluminum, arsenic, iron, manganese)

These constituents were identified as COPCs for sediment because the maximum detected concentrations exceeded screening levels based on the ORNL RSLs for residential soil and MDEQ Tier 1 TRGs for unrestricted land use. In addition, the maximum concentration of arsenic also exceeded the MDEQ TRG for restricted soil. The use of the ORNL residential soil RSLs and MDEQ TRGs for soil to evaluate COPC concentrations in sediment is conservative because these criteria were established assuming residential land use scenarios (e.g., routine daily contact with soils). However, it is anticipated that a human receptor would be exposed to the sediments at Site 1 on a less frequent basis than is

assumed for a typical residential exposure to soil. Consequently, the use of soil criteria for COPC screening and risk estimation is likely to overestimate potential risks from exposure to sediment.

6.3.7 Summary

Table 6-11 summarizes the chemicals retained as COPCs for soil, groundwater, surface water, and sediment at Site 1. RAGS Part D tables for COPC selection are included in Appendix E-1.

6.4 EXPOSURE ASSESSMENT

The exposure assessment estimates the extent of human contact with COPCs by characterizing potentially exposed populations of individuals (i.e., receptors), identifying actual or potential pathways of exposure that are appropriate for each potential receptor, and estimating the extent of human exposure.

An exposure pathway identifies the exposure routes for potentially complete pathways at the site and describes the mechanism by which human receptors may come into contact with site-related COPCs. Exposure pathways are dependent on both current and future land use. An exposure pathway is defined by four elements (USEPA, 2005f):

- A source material and mechanism of constituent release to the environment.
- An environmental migration or transport medium (e.g., soil) for the COPCs.
- A point of potential human contact with the medium of interest (e.g., potential exposure to the contaminated soil).
- An exposure route (e.g., ingestion, dermal contact) at the point of contact.

An exposure pathway is considered "complete" if all elements are present. If complete and significant, these pathways are quantitatively evaluated in the risk assessment.

The potential for exposure at Site 1 is based on several factors, including current and future land uses, human activity patterns, site access controls, chemical behavior in the environment, and the presence of human receptors. Based on these variables, exposure scenarios are developed which characterize the potential for human exposure under both current and future site conditions. The future scenario accounts for potential or anticipated changes in land use and site characteristics that may alter exposure conditions at the site. The Exposure Assessment assumes that, in general, chemical compositions for environmental media are identical under current and future site conditions.

The Exposure Assessment presented in this section of the report describes the physical site setting and the potential receptors of concern, identifies the potential contaminant migration and exposure pathways,

defines the contaminant concentrations at the point of exposure, and presents the equations used to quantify exposure in terms of contaminant intake (dose). Appendix E-1 presents calculations of the chemical-specific intakes for all receptors and exposure pathways and Appendix E-2 contains example calculations of the chemical intakes.

A summary of the potentially significant exposure pathways identified for quantitative evaluation for Site 1 is provided in Table 6-12. Rationales for the selection or elimination of exposure pathways are presented in RAGS-Part D Table 1 in Appendix E-1.

6.4.1 Land Use and Site Access

Site 1 is a former landfill approximately 9 acres in size and located north of 7th street and east of Colby Avenue. The site has most recently been used as a mock disaster recovery training village and as a training facility.

As indicated in Section 2 of the work plan, solid wastes along with some liquid wastes, including waste fuel, oil, solvents, paint thinners, were disposed of at the site during the site landfill's operation between 1942 and 1948. Liquid wastes were reportedly transported to the site in 55-gallon drums and buried. The waste disposal area was covered with soil when disposal activities ended in 1948, and additional fill has been added since then due to parking lot and road construction. As mentioned above, Site 1 has most recently been used as a training facility. Access to the site is not restricted and older children could potentially play on the site.

6.4.2 Conceptual Site Model (CSM)

The development of a CSM is an essential component of the exposure assessment. The CSM integrates information regarding the physical characteristics of the site, exposed populations, sources of contamination, and contaminant mobility (fate and transport) to identify potential exposure routes and receptors to be evaluated in the risk assessment. A well-developed CSM will allow for a better understanding of the risks at a site and will aid risk managers in identifying the potential need for both environmental sampling and remediation. The site-specific CSM for Site 1 is presented in this section.

Table 6-12 presents a summary of the exposure pathways that are addressed quantitatively for each human receptor. The CSM depicts the relationships among the following elements:

- Site sources of contamination
- Contaminant release mechanisms
- Transport/migration pathways

- Exposure routes/pathways, and
- Potential receptors

These elements of the CSM for Site 1 are discussed in the following sections.

6.4.2.1 Site Sources of Contamination/Release Mechanisms/Migration Pathways

Previous investigations have identified that liquid and solid wastes (e.g., paint disposal waste containing metals) were landfilled at Site 1. Contaminant migration (e.g., migration from wastes/soils to groundwater) has occurred as a consequence of the leaching of the waste materials interred at the landfill.

Based on historical site data and sampling, the following parameters are among the site-related chemical contaminants known to be present or potentially present in environmental media at Site 1:

- VOCs (e.g. vinyl chloride, trichloroethene)
- SVOCs (e.g. benzo(a)pyrene equivalents)
- Pesticides/PCBs (alpha-BHC, dieldrin)
- Metals (e.g. arsenic, iron)

The topography at Site 1 is relatively flat and the ground surface is primarily fill dirt and native sand with predominantly grassy vegetative cover. Roads and structures from the disaster recovery training area are present at the site. Surface water drainage at the site is to the west to the ditch adjacent to Colby Avenue, which drains into Canal No. 1. Canal No. 1 conveys surface water north where it exits the base through a culvert under 28th Street. The depth to groundwater at Site 1 is approximately 3 feet bls. The surface material is a fine to medium sand with minor silt, which is unlikely to prevent infiltration into the landfill.

Potential contaminant release mechanisms at Site 1 include the mobilization of contaminants from wastes buried in subsurface soil to local groundwater by infiltration of precipitation and dissolution of soluble contaminants. Soluble constituents can then be transported to the shallow aquifer by rainwater infiltration, at which point they may continue to move hydrologically downgradient. It is also possible that contaminants may migrate vertically. It should be noted that, drinking water supply wells in this area are typically screened at approximately 500 feet bls, and a significant confining layer is present at about 150 to 250 feet bls. This confining layer was identified and reported by the Office of Land and Water Resources in Public Water Supply (PWS). Report PWS-ID: 240005 Source ID: 12 (1993) and pertains to wells installed within 2 miles of Site 1.

Contaminant transport is affected by the chemical and physical properties of both the soil and the contaminants. Figure 3-2 presents the site conceptual model that illustrates these potential contaminant migration pathways for Site 1. Another potential contaminant migration mechanism for Site 1 is the discharge of the local, shallow groundwater to drainage ditches on the site. If disturbed, contaminants in surface soil could also migrate from the site as consequence of airborne particulate emissions or volatilization of VOCs.

6.4.2.2 Potential Receptors

NCBC Gulfport is an active facility and will remain active for the foreseeable future. Site 1 is currently a training facility and is expected to be used for this purpose in the foreseeable future. Access to the site is not restricted and older children could potentially play on the site. Because the site is currently active and access is not limited, the baseline HHRA considered receptor exposure under residential, industrial, and trespasser/recreational user land use scenarios. Based on current and potential future land use, the following potential receptors described below and in Table 6-12 may be exposed to contaminated environmental media within the study area.

Construction/Excavation Workers – Receptors under future land use. Construction activities are currently planned for the study area. Construction workers are considered for future land use only and are assumed to be exposed to surface/subsurface soil and sediment (by ingestion and dermal contact), groundwater (by dermal contact and inhalation of volatiles), surface water (by ingestion and dermal contact), and air (by fugitive dust and vapors if subsurface soil is excavated).

Site Commercial/Industrial Workers – Receptors under current and future land use. This includes adult military and civilian personnel working daily at Site 1. These workers are assumed to be exposed to surface soil, subsurface soil, and sediment (by ingestion and dermal contact) and to surface water (by dermal contact and ingestion).

On-Site Maintenance Workers – Receptors under current and future land use. This receptor scenario includes adult military and civilian personnel assigned to routine maintenance/security tasks for the training facility and base security. This receptor is assumed to be exposed to surface soil, subsurface soil, and sediment (by ingestion and dermal contact) and to surface water (by dermal contact and ingestion).

Recreational Users/Trespassers (Adolescent and Adult) – Receptors under current and future land use. This receptor is assumed to be exposed to surface soil, subsurface soil, and sediment (by ingestion and dermal contact) and to surface water (by dermal contact and ingestion).

Residents (Child and Adult) – Receptors under future land use. Although a future on-site residential scenario is highly unlikely, a future residential scenario is typically evaluated in a risk assessment for decision-making purposes. It is assumed that a hypothetical resident may be exposed to surface soil, subsurface soil, and sediment (by ingestion and dermal contact), groundwater (by ingestion, dermal contact, and inhalation of volatiles), and surface water (by dermal contact and ingestion). Because the potential for residential housing on land adjacent to the site cannot be entirely discounted, off-site residents are considered plausible receptors under future land use. Conservatively, off-site residents are assumed to be exposed to site contaminants in the same manner as on-site residents would be.

6.4.3 Central Tendency Exposure vs. Reasonable Maximum Exposure

Traditionally, exposures evaluated in the HHRA were based on the concept of a reasonable maximum exposure (RME) only, which is defined as "the maximum exposure that is reasonably expected to occur at a site" (USEPA, 1989). However, recent risk assessment guidance (USEPA, 1992) indicates the need to address an average case or central tendency exposure (CTE).

To provide a full characterization of potential exposure, both RME and CTE are evaluated for Site 1. The available guidance (USEPA, 1993d) concerning the evaluation of CTE is limited and, at times, vague. Therefore, professional judgment was exercised when defining CTE conditions for a particular receptor. Exposure factors and assumptions for the CTE are presented and discussed in Section 6.4.5.

6.4.4 Exposure Point Concentrations

The exposure point concentration (EPC), which is calculated for COPCs only, is a reasonable maximum estimate of the chemical concentration that is likely to be contacted over time by a receptor and is used to calculate estimated exposure intakes.

The following guidelines were used to calculate the EPCs for soil, groundwater, surface water and sediment at Site 1:

- If a soil, surface water, or sediment dataset contained fewer than 10 samples, the EPC for the RME and CTE cases was defined as the maximum detected concentration.
- If a soil, surface water, or sediment dataset contained 10 or more samples, the 95-percent upper confidence limit (UCL) on the arithmetic mean, which was based on the distribution of the data set, was selected as the EPC for the RME and CTE cases. EPCs were calculated following USEPA's Calculating UCLs for EPCs at Hazardous Waste Sites (USEPA, 2002c) using the USEPA's ProUCL software and guidance (USEPA, 2007a). In general, the concentration

selected for the EPC is the value recommended by the ProUCL software, subject to final review by a statistician.

- USEPA Region IV (USEPA, 2000a) makes an exception to the use of the UCL as the EPC for groundwater. According to the Region IV guidance, groundwater EPCs should be the arithmetic average of the wells in the highly concentrated area of the plume. However, evaluating the locations of positive detections for groundwater COPCs did not reveal a well-defined contaminant plume. Therefore, the maximum detected concentrations were used as EPCs for groundwater COPCs. Using maximum concentrations is a more conservative approach than using the average concentrations from wells of the area of highest concentration because it assumes that receptors are exposed to the greatest concentration at the site for the entire exposure duration, which is unlikely.

Prior to statistical analysis (e.g., distribution analyses, the calculation of basic descriptive statistics and UCLs, etc.), non-detect results were assigned a value of one-half the sample quantitation limit. Rejected values ("R" flagged during data validation) were eliminated from further consideration because they were regarded as unreliable. Estimated and biased values (flagged "J") were used at the reported value with the realization that some uncertainty is associated with the reported numerical result. When duplicate sample pairs are reported, the sample and duplicate were considered as two separate samples when determining the minimum and maximum detected concentrations, but the average of the original and duplicate samples was used for all calculations.

USEPA Region IV has adopted a Toxicity Equivalence Factor (TEF) approach to evaluate potentially carcinogenic PAHs. These TEFs are based on the relative potency of each compound relative to that of benzo(a)pyrene. The TEFs are used to convert each individual carcinogenic PAH concentration into an equivalent concentration of benzo(a)pyrene. Using individual benzo(a)pyrene equivalent concentrations, an EPC for carcinogenic PAHs is derived. If all the carcinogenic PAHs were not detected in a sample, then one half the sample quantitation limit for benzo(a)pyrene was used as the equivalent concentration for that sample. The TEF approach was used for the sediment dataset only, because in all other media carcinogenic PAHs were either not detected or only one carcinogenic PAH was detected.

The EPCs for the chemicals identified as COPCs in environmental media at Site 1 are presented in Table 6-13 and the RAGS-Part D Tables in Appendix E-1.

6.4.5 Intake Estimation Methods and Exposure Parameters

To determine potential human health risks associated with Site 1, an estimate of chemical intake was made in accordance with current USEPA guidance. Exposure parameters and exposure concentrations are used

to derive estimates of chemical intake for each exposure route, pathway, and receptor. The resulting chemical intakes are integrated with the toxicity factors discussed in Section 6.5 to develop quantitative risk estimates for potential receptors at the site. Intakes for the identified potential receptor groups are calculated using current USEPA risk assessment guidance (USEPA, 1989; 2004c) and presented in the risk assessment spreadsheets (Appendix E-1). In accordance with current USEPA guidance chemical intakes (and risks) are estimated for both the CTE and RME conditions. Values of exposure parameters used to quantify exposure for each receptor are presented in Tables 6-14 and 6-15 for the RME and CTE, respectively.

The following sections present the equations used to estimate chemical intakes for the exposure routes identified for quantitative evaluation. Example calculations for estimated intakes are provided in Appendix E-2. Calculations of estimated intakes for all potential receptors are contained in Appendix E-1.

6.4.5.1 Exposure to COPCs in Soil/Sediment

The HHRA assumes that site maintenance workers, construction/excavation workers, industrial workers, trespassers (adults and adolescents), and potential future residents may come into contact with chemicals detected in soil or sediment at the site. Soil/sediment exposure routes are incidental ingestion and dermal contact. A description of the methods and assumptions used to quantify soil and sediment exposure follows.

Incidental Ingestion of Soil/Sediment. Intakes associated with soil ingestion are estimated using the following equation (USEPA, 1989):

$$\text{Intake} = \frac{C \times IR \times FI \times EF \times ED \times CF}{BW \times AT}$$

where:

Intake	=	ingestion intake
C	=	chemical concentration in soil or sediment (mg/kg)
IR	=	soil/sediment ingestion rate (mg/day)
FI	=	fraction ingested from contaminated source (unitless)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (years)
CF	=	conversion factor (1 x 10 ⁻⁶ kg/mg)
BW	=	body weight (kg)
AT	=	averaging time (days)
		for noncarcinogens: 365 days/year x ED
		for carcinogens: 365 days/year x 70 years

Incidental ingestion rates for potential receptors are based on the recommendations contained in current risk guidance for the evaluation of the CTE and RME (USEPA, 1993d). Children are assumed to ingest more soil than adults as a result of normal behavior such as purposely placing dirty objects in their mouth and unintentional hand-to-mouth activities. The following ingestion rates for the CTE are used to quantify risks in this HHRA: 100 mg/day for child residents, 50 mg/day for adult residents, adult and adolescent trespassers, industrial workers, and site maintenance workers. Construction workers are expected to have higher than average soil ingestion rates (165 mg/day) because of the increased potential for soil contact typically associated with ground-intrusive activities (USEPA, 2002c). For the RME, the following ingestion rates are used to quantify risks: 200 mg/day for child residents, 100 mg/day for adult residents, adolescent trespassers, and site maintenance workers, 50 mg/day for adult trespassers and industrial workers, and 330 mg/day for construction workers. The fraction of soil ingested from the contaminated source is conservatively assumed to be 1.0 for both the CTE and RME.

Site maintenance workers are assumed to be exposed to soil 12 days/year for 9 years for the CTE and 24 days/year for 25 years for the RME. Construction workers are assumed to be exposed to soil 250 days/year for one year for the RME and 125 days/year for one year for the CTE. Industrial workers are assumed to be exposed to soil 250 days/year for 25 years for the RME and 219 days/year for 9 years for the CTE. Adolescent trespassers are assumed to be exposed to soil 15 days/year for 11 years for the CTE and 30 days/year for 11 years for the RME. Adult trespassers are assumed to be exposed to soil 15 days/year for 19 years for the CTE and 30 days/year for 19 years for the RME. Residents are assumed to be exposed to soil 234 days per year for 9 years (2 years child + 7 years adult) for the CTE and 350 days/year for 30 years (6 years child + 24 years adult) for the RME.

For exposure to sediment, site maintenance workers and industrial workers are assumed to be exposed 24 days/year for the RME and 12 days/year for the CTE. Adolescent trespassers are assumed to be exposed to sediment 30 days/year for the RME and 15 days/year for the CTE. Adult trespassers are assumed to be exposed to sediment 30 days/year for the RME and 15 days/year for the CTE. Construction/excavation workers and future residents are assumed to be exposed to sediment 30 days/year for the RME and 15 days/year for the CTE.

Adults (workers, trespassers, and residents) are assumed to weigh 70 kilograms (kg). The body weight for adolescent trespassers (ages 6 to 16) is specified as 45 kg, and the weight of the child resident (0 to 6 years) is assumed to be 15 kg.

Exposure parameters for the soil ingestion route are summarized in Tables 6-14 and 6-15.

Dermal Absorption of Soil/Sediment. Doses for dermal contact with soil and sediment are estimated using the following equation (USEPA, 2004c):

$$DEX = \frac{C \times SA \times AF \times ABS \times EF \times ED \times CF}{BW \times AT}$$

where:

DEX	=	dermal dose (mg/kg-day)
C	=	chemical concentration in soil or sediment (mg/kg)
SA	=	skin surface area available for contact (cm ² /day)
AF	=	soil-to-skin adherence factor (mg/cm ²)
ABS	=	absorption factor (unitless)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (years)
CF	=	conversion factor (1 x 10 ⁻⁶ kg/mg)
BW	=	body weight (kg)
AT	=	averaging time (days)
		for noncarcinogens: 365 days/year x ED
		for carcinogens: 365 days/year x 70 years

Exposed surface areas of the body available for dermal contact are determined for each receptor based on assumed human activities and clothing worn during exposure events. USEPA guidance (USEPA, 1997c; 2004c) was used to develop the default assumptions concerning the amount of skin surface area available for contact for a receptor. The skin surface areas used in risk assessment calculations and the rationale for the selection of the surface areas are defined as follows:

- For adolescent trespassers, 25 percent of the total surface area is assumed to be available for contact with soil. This skin surface area is assumed to be 3,250 square centimeters (cm²) for the RME and CTE scenarios (USEPA, 1997c).
- The head, hands, and forearms of site maintenance workers, industrial workers, and excavation/construction workers are assumed to be available for contact (assuming that they wear a short-sleeved shirt, long pants, and shoes). As recommended in RAGS Part E (USEPA, 2004c), this skin surface area is assumed to be 3,300 cm² for the RME and CTE scenarios. This value represents the average of the 50th percentile areas of males and females more than 18 years old.
- For adult trespassers and adult residents assumed to be exposed to soil and sediment, the exposed surface areas available for contact are the values for the adult skin surface area for

exposure to soil recommended in RAGS Part E (USEPA, 2004c), 5,700 cm² for the RME and for the CTE. This skin area assumes that the head, hands, forearms, and lower legs of the adult are available for contact.

- For child residents assumed to be exposed to soil and sediment, the exposed surface areas available for contact are the values for child skin surface area for exposure to soil recommended in RAGS Part E (USEPA, 2004c), 2,800 cm² for the RME and for the CTE. This skin area assumes that the head, hands, forearms, lower legs, and feet of the child are available for contact.

The soil to skin adherence factors and chemical-specific dermal absorption factors provided in RAGS Part E (USEPA, 2004c) are used to evaluate risks from exposure to soil. The following soil adherence factors are used for the RME and CTE exposure scenarios:

- Industrial and site maintenance workers – 0.2 (mg/cm²) for the RME and 0.02 mg/cm² for the CTE (Exhibit 3.5, USEPA, 2004c).
- Construction workers – 0.3 mg/cm² for the RME and 0.1 mg/cm² for the CTE (Exhibit 3.3, USEPA, 2004c).
- Adult trespassers and adult residents – 0.07 mg/cm² for the RME and 0.01 mg/cm² for the CTE (Exhibit 3.5, USEPA, 2004c).
- Adolescent trespassers – 0.4 mg/cm² for the RME and 0.04 mg/cm² for the CTE (Exhibit 3.3, USEPA, 2004c).
- Child residents – 0.2 mg/cm² for the RME and 0.04 mg/cm² for the CTE (Exhibit 3.5, USEPA, 2004c).

For the constituents identified as COPCs in soil and sediment, the following dermal absorption factors are used in this HHRA (USEPA, July 2004):

- PAHs - 0.13
- Dieldrin – 0.1
- Aroclor-1242 – 0.14

- Arsenic – 0.03
- Other Metals and Volatiles - not evaluated for dermal contact with soil (RAGS-Part E does not provide absorption factors for metals other than arsenic and cadmium).

The same exposure frequencies, exposure durations, and body weights previously identified for ingestion route of exposure are used to characterize dermal contact with soil and sediment. Exposure parameters for the soil/sediment dermal absorption route are summarized in Tables 6-14 and 6-15.

6.4.5.2 Exposure to Groundwater

Future residential and construction worker, scenarios were developed for exposure to groundwater primarily using current risk assessment guidance (USEPA, December 1989, May 1993, and July 2004). The applicable groundwater exposure frequencies, exposure durations, and body weights for residents are identical to those previously identified for soil contact.

Ingestion of Groundwater

Intakes for direct ingestion of groundwater are estimated using the following general equation (USEPA, 1989):

$$\text{Intake} = \frac{C \times IR \times EF \times ED}{BW \times AT}$$

where:

Intake	=	ingestion intake (mg/kg-day)
C	=	chemical concentration in groundwater (mg/L)
IR	=	ingestion rate (L/day)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (years)
BW	=	body weight (kg)
AT	=	averaging time (days)
		for noncarcinogens: 365 days/year x ED
		for carcinogens: 365 days/year x 70 years

Water ingestion rates for the adult resident are specified as 1.4 L/day (CTE) and 2.0 L/day (RME). For the child resident, water ingestion rates are 0.66 L/day (CTE) and 1.5 L/day (RME).

Dermal Contact with Groundwater

The following equations are used to estimate doses resulting from dermal contact with groundwater (USEPA, 2004c):

$$DAD = \frac{DA_{event} \times EV \times EF \times ED \times A}{BW \times AT}$$

where:

DAD	=	dermal dose (mg/kg-day)
DA _{event}	=	dose per event (mg/cm ² /event)
EV	=	event frequency (events/day)
ED	=	exposure duration (years)
EF	=	exposure frequency (days/year)
A	=	skin surface area available for contact (cm ²)
BW	=	body weight (kg)
AT	=	averaging time (days)

for noncarcinogens: 365 days/year x ED
for carcinogens: 365 days/year x 70 years

The absorbed dose per event (DA_{event}) is estimated using a nonsteady-state approach for organic compounds and a traditional steady-state approach for inorganics. The following equations apply for organic chemicals:

$$\text{If } t_{event} < t^*, \text{ then: } DA_{event} = 2 \times FA \times K_p \times C \times CF \times \left(\frac{\sqrt{6 \tau t_{event}}}{\pi} \right)$$

$$\text{If } t_{event} > t^*, \text{ then: } DA_{event} = FA \times K_p \times C \times CF \times \left(\frac{t_{event}}{1+B} + 2 \tau \left(\frac{1+3B+3B^2}{(1+B)^2} \right) \right)$$

where:

t _{event}	=	duration of event (hour/event)
t [*]	=	time it takes to reach steady-state conditions (hour)
FA	=	fraction absorbed (dimensionless) – chemical specific
K _p	=	permeability coefficient from water through skin (cm/hour)
C	=	concentration of chemical in surface water (mg/L)
τ	=	lag time (hour)
π	=	constant (unitless; equal to 3.1416)
CF	=	conversion factor (1x10 ⁻³ L/cm ³)
B	=	partitioning constant derived by Bunge Model (dimensionless)

Values for the chemical-specific parameters (t^* , K_p , τ , and B) are obtained from the current dermal guidance (USEPA, 2004c, Exhibit B-3) and are presented in Appendix E-1. If published values are not available for a particular compound, they were calculated using equations provided in the USEPA dermal guidance.

The following equation was used to estimate DA_{event} for inorganics:

$$DA_{\text{event}} = K_p \times C \times t_{\text{event}}$$

The recommended default value of 1×10^{-3} was used for inorganic chemicals, unless chemical-specific data were available in RAGS-Part E.

Whole body contact was assumed for dermal contact with groundwater for the residential scenario. A value of $18,000 \text{ cm}^2$ is used for the adult resident for both the CTE and RME scenario (USEPA, 2004c). For the child resident, a skin surface area of $6,600 \text{ cm}^2$ is used for the CTE and RME scenarios. For excavation/construction workers exposed to groundwater, the exposed skin surface area is assumed to be 3300 cm^2 (USEPA, 1997c). This assumes that approximately 18 percent of the total body surface area is available for contact with groundwater. The estimated exposure time (i.e., length of shower or bath) is 15 minutes for the CTE and 20 minutes for the RME. Construction/excavation workers are assumed to be exposed to shallow groundwater in a trench 4 hours/day for the RME and 2 hours/day for the CTE. An event frequency of one per day is assumed for the CTE and RME (residents were assumed to take one shower or bath per day).

Exposure parameters for exposure to groundwater are summarized in Tables 6-14 and 6-15.

Inhalation of Volatiles in Groundwater

Groundwater exposure may also result in chemical intake through inhalation if the water resource is used as a domestic water supply or is exposed during construction activities, and VOCs are present in the groundwater. This exposure route is plausible for residential receptors that may be exposed while showering, bathing, washing dishes, etc., or for construction workers contacting shallow groundwater during excavation activities. Per USEPA Region IV risk assessment protocol, it will be assumed that the chemical intake resulting from a showering exposure is equivalent to the chemical intake from ingestion of two liters of water.

Inhalation of Volatiles via Vapor Intrusion from Groundwater into Indoor Air

Volatilization of chemicals from groundwater into indoor air may occur, thereby exposing individuals inside buildings or dwellings. Therefore, potential risks associated with chemical concentrations in indoor

air as a result of vapor migration from impacted groundwater are evaluated for industrial workers and hypothetical future residents. The Johnson and Ettinger Vapor Intrusion Model (USEPA, 2004b) is used to determine the indoor air concentration of a chemical that is present in groundwater. The model assumes that vapors of volatile chemicals are emitted from groundwater, migrate through surface and subsurface soil, through cracks in the building foundation, and accumulate in air inside buildings. The Johnson and Ettinger model assumes that residential dwellings have been constructed on the site and that the dimensions of these buildings and ventilation rates are typical of residential dwellings in the United States. The results of the vapor intrusion evaluation are presented in the uncertainty section (Section 6.7.3.6) due to the uncertainty associated with the EPCs generated using the Johnson and Ettinger volatilization model. Input values and results of the vapor intrusion model are included in Appendix E-3.

Exposure of Workers to Volatiles in a Construction/Utility Trench

Construction workers may be exposed to COPCs that have volatilized from groundwater when excavation exposes the shallow groundwater table. Construction worker exposure associated with the inhalation route was estimated in the following manner (USEPA, 2009):

$$EC = \frac{(C_{air})(ET)(EF)(ED)}{(AT)}$$

where:

EC	=	exposure concentration (mg/m ³)
C _{air}	=	concentration of chemical in air (mg/m ³)
ET	=	exposure time (hours/day)
EF	=	exposure frequency (days/yr)
ED	=	exposure duration (yr)
AT	=	averaging time (days); for noncarcinogens, AT = ED x 365 days/yr x 24 hours/day; for carcinogens, AT = 70 yr x 365 days/yr x 24 hours/day

The same exposure frequency and exposure time used to estimate intake from dermal contact with groundwater were used to evaluate intake from inhalation of VOCs from groundwater during construction activities.

There are no well-established models available for estimating migration of volatiles from groundwater into a construction/utility trench. To estimate the EPC for air in a construction trench, this HHRA uses the approach suggested by the Virginia Department of Environmental Quality (VDEQ, 2004), which is based

on a combination of a vadose zone model (to estimate volatilization of gases from contaminated groundwater into a trench) and a box model (to estimate dispersion of the contaminants from the air inside the trench into the above-ground atmosphere). The VDEQ methodology is described in the following paragraphs.

The airborne concentration of a contaminant in a trench can be estimated using the following equation:

$$C_{\text{air}} = C_{\text{GW}} \times \text{VF}$$

where:

C_{air} = air concentration of contaminant in the trench $\mu\text{g}/\text{m}^3$

C_{GW} = concentration of contaminant in groundwater $\mu\text{g}/\text{L}$

VF = volatilization factor L/m^3

It is assumed that a construction project could result in an excavation of 15 feet bls or less. If the depth to groundwater at a site is less than 15 feet, the VDEQ model assumes that a worker would encounter groundwater when digging an excavation ditch or a trench. The worker would then have direct exposure to the groundwater. The worker would also be exposed to contaminants in the air inside the trench that would result from volatilization from the groundwater pooling at the bottom of the trench.

The following equation is used to calculate the volatilization factor (VF) for a trench less than 15 feet deep:

$$\text{VF} = (K_i \times A \times F \times 10^{-3} \times 10^4 \times 3,600) / (\text{ACH} \times V)$$

where:

K_i = overall mass transfer coefficient of contaminant (cm/s)

A = area of the trench (m^2)

F = fraction of floor through which contaminant can enter (unitless)

ACH = air changes per hour (h^{-1}) = 360 h^{-1}

V = volume of trench (m^3)

10^{-3} = conversion factor (L/cm^3)

10^4 = conversion factor (cm^2/m^2)

3,600 = conversion factor (seconds/hour)

Studies of urban canyons suggest that if the ratio of trench width, relative to wind direction, relative to trench depth is less than or equal to 1, a circulation cell or cells will be set up within the trench that limits

the degree of gas exchange with the atmosphere and, based upon measured ventilation rates of buildings, the air changes per hour (ACH) is assumed to be 2. Based upon the ratio of trench depth to the average wind speed, if the ratio of trench width to trench depth is greater than 1, the air exchange between the trench and above-ground atmosphere is not restricted, and the ACH is assumed to be 360. The exposure assessment performed for these HHRAs assumes the width-to-trench depth ratio is greater than 1; therefore, the ACH is set at 360.

K_i is calculated using the following equation:

$$K_i = 1 / \{ (1/k_iL) + [(RT) / (H_i k_iG)] \}$$

where:

K_i	=	overall mass transfer coefficient of containment (cm/s)
k_iL	=	liquid-phase mass transfer coefficient of i (cm/s)
R	=	ideal gas constant (atm-m ³ /mole-°K) = 8.2×10^{-5}
T	=	average system absolute temperature (°K) (Default = 298°K)
H_i	=	Henry's Law constant of i (atm-m ³ /mole)
k_iG	=	gas-phase mass transfer coefficient of i (cm/s)

The formulas for calculating k_iL and k_iG are as follows:

$$k_iL = (MWO_2/MW_i)^{0.5} \times (T/298) \times kL_{O_2}$$

where:

k_iL	=	liquid-phase mass transfer coefficient of component i (cm/s)
MWO_2	=	molecular weight of oxygen (g/mole)
MW_i	=	molecular weight of component i (g/mole)
kL_{O_2}	=	liquid-phase mass transfer coefficient of oxygen at 25°C (cm/s) = 0002 cm/s

$$k_iG = (MWH_2O/MW_i)^{0.335} \times (T/298)^{1.005} \times kG_{H_2O}$$

where:

- k_iG = gas-phase mass transfer coefficient of component i (cm/s)
 MW_{H_2O} = molecular weight of water (g/mole)
 k_{G,H_2O} = gas-phase mass transfer coefficient of water vapor at 25°C (cm/s)=
 0.833 cm/s (Superfund Exposure Assessment Manual, USEPA, 1988).

Chemical properties were obtained from the Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites (USEPA, 2002b).

6.4.5.3 Exposure to Surface Water

Direct contact with surface water may occur while potential receptors are involved in work or play at Site 1. Since surface water is only present on the site during and immediately after storm events, swimming is not likely to occur on Site.1. Therefore, this scenario conservatively assumes that receptors are exposed by incidental ingestion and dermal contact while wading. Ingestion of surface water is conservatively evaluated but it is not expected to be a significant exposure pathway for the wading scenario.

Incidental Ingestion of Surface Water

Potential receptors may incidentally ingest small amounts of surface water while wading in Canal No. 1. Intakes associated with ingestion of surface water were evaluated using the following equation (USEPA, 1989):

$$\text{Intake}_{wi} = \frac{(C_{wi})(IR_w)(ET)(EF)(ED)}{(BW)(AT)}$$

where:

- Intake_{wi} = intake of chemical "i" from water (mg/kg/day)
 C_{wi} = concentration of chemical "i" in water (mg/L)
 IR_w = ingestion rate for surface water (L/hour)
 ET = exposure time for surface water (hour/day)
 EF = exposure frequency (days/year)
 ED = exposure duration (year)
 BW = body weight (kg)
 AT = averaging time (days);
 for noncarcinogens, $AT = ED \times 365$ days/year;
 for carcinogens, $AT = 70$ years \times 365 days/year

An ingestion rate of 0.01 L/hour is used for adults and adolescents under CTE and RME conditions and 0.05 L/hour for children (USEPA, 2000a). Exposure times, which are based on professional judgment with consideration of anticipated activities, are specified as 1.0 hour/day for the CTE and RME. Because surface water and sediment exposure coincides, the same exposure durations and frequencies previously identified for exposure to sediment are used to evaluate inadvertent surface water ingestion. Exposure factor values for ingestion of surface water are summarized in Tables 6-14 and 6-15.

The same equations used to assess dermal exposure to groundwater are used to evaluate dermal exposure to surface water. The following skin surface areas are used for evaluating dermal exposure to surface water: 3300 cm² is used as the exposed surface area for site maintenance workers, excavation/construction workers, and industrial workers, for the CTE and RME; 3,250 cm² is used for adolescent trespassers and 2800 cm² is used as the exposed skin surface area for child residents. 5700 cm² is used for adult trespassers and adult residents. The same exposure times, frequencies, and durations used to assess ingestion of surface water were used to estimate intakes for dermal exposure.

6.4.5.4 Exposures to Lead

Lead was not selected as a COPC for direct contact scenarios in the environmental media at Site 1 and therefore is not anticipated to pose a threat to human health through direct contact pathways. Lead was only selected as a COPC for the surface soil migration to groundwater pathway, and the migration to groundwater pathway is not evaluated quantitatively in this HHRA. Therefore, the methodology for evaluating exposures to lead is not presented.

6.5 TOXICITY ASSESSMENT

Oral and inhalation RfDs and CSFs used in the HHRA for Site 1 were obtained from the following primary literature sources:

- IRIS (online at <http://cfpub.epa.gov/ncea/iris/index.cfm>).
- USEPA Provisional Peer Reviewed Toxicity Values – The Office of Research and Development/National Center for Environmental Assessment Superfund Health Risk Technical Support Center develops Provisional Peer Reviewed Toxicity Values on a chemical-specific basis when requested by USEPA's Superfund program.
- Other Toxicity Values – These sources include but are not limited to California Environmental Protection Agency (Cal EPA) toxicity values, the Agency for Toxic Substances and Disease Registry (ATSDR) Minimal Risk Levels, and the Annual Health Effects Assessment Summary Tables (HEAST) (USEPA, 1997b).

Although RfDs and CSFs can be found in several toxicological sources, USEPA's IRIS on-line database is the preferred source of toxicity values. This database is continuously updated and values presented have been verified by USEPA. The ORNL RSL Table (April 15, 2009) was also used as a source of toxicity criteria when the criteria were not available from the aforementioned references. The RfDs and CSFs for the constituents selected as COPCs for Site 1 are presented in Tables 6-16 through 6-19.

6.5.1 Toxicity Criteria for Dermal Exposure

RfDs and CSFs found in literature are typically expressed as administered doses; therefore, these values are considered inappropriate for estimating the risks associated with dermal routes of exposure. Oral dose-response parameters based on administered doses must be adjusted to absorbed doses before the evaluation of estimated dermal exposure intakes is made.

The adjustment from administered to absorbed dose was made using chemical-specific absorption efficiencies published in available guidance [i.e., USEPA, 2004c (the primary reference), IRIS, ATSDR toxicological profiles, etc.] and the following equations:

$$\begin{aligned} \text{RfD}_{\text{dermal}} &= (\text{RfD}_{\text{oral}})(\text{ABS}_{\text{GI}}) \\ \text{CSF}_{\text{dermal}} &= (\text{CSF}_{\text{oral}}) / (\text{ABS}_{\text{GI}}) \end{aligned}$$

where: ABS_{GI} = absorption efficiency in the gastrointestinal tract.

Absorption efficiencies used in the risk assessments reflect USEPA's current dermal assessment guidance (USEPA, 2004c).

6.5.2 Toxicity Criteria for Carcinogenic Effects of PAHs

Limited toxicity values are available to evaluate the carcinogenic effects from exposure to PAHs. The most extensively studied PAH is benzo(a)pyrene, which is classified by USEPA as a probable human carcinogen. Although CSFs are available for benzo(a)pyrene, insufficient data are available to calculate CSFs for other carcinogenic PAHs. Toxic effects for these chemicals were evaluated using the concept of estimated orders of potential potency, which relate the potency of the other potentially carcinogenic PAHs to the potency of benzo(a)pyrene, as presented in current USEPA guidance (USEPA, 1993e). The equivalent oral and inhalation CSFs for these chemicals were derived by multiplying the CSFs for benzo(a)pyrene by the orders of potential potency.

USEPA's Guidelines for Carcinogen Risk Assessment (USEPA, 2005e) and Supplemental Guidance of Assessing Susceptibility from Early-Life Exposure to Carcinogens (USEPA, 2005f) specifies the use of age-dependent adjustment factors (ADAFs) for carcinogens that act via a mutagenic mode of action. Carcinogenic PAHs are included in the group of chemicals that have been determined to act via the mutagenic mode of action. No chemical-specific ADAFs have been derived for carcinogenic PAHs, therefore the following default ADAFs were used: 10 for ages 0 to 2, 3 for ages 2 to 16, and 1 (no adjustment) for ages 16 to 70. The ADAFs were used in evaluating exposures to carcinogenic PAHs for adolescent trespassers and hypothetical residents.

6.5.3 Toxicity Criteria for Chromium

Toxicity criteria are available for different forms of chromium, which is considered to be more toxic in the hexavalent state. Because there is no evidence to support the conclusion that hexavalent chromium is present at Site 1, speciation analyses were not completed for samples collected at Site 1. However, risks associated with this chemical were assessed by conservatively assuming that 100 percent of the chromium detected in an environmental medium is present in the hexavalent state.

6.5.4 Toxicity Criteria for Trichloroethene

Toxicity criteria (i.e., RfDs, CSFs) for trichloroethene are not currently published on the USEPA's IRIS database or in HEAST. As per Navy policy, the Cal EPA values (Cal EPA, 2002) were used to estimate risks for trichloroethene in this risk assessment. The uncertainty associated with the use of the California EPA toxicity values relative to draft USEPA values is discussed in Section 6.7.4.4.

6.6 RISK CHARACTERIZATION

The baseline HHRA evaluates potential health risks associated with human exposure to chemicals present at Site 1. Quantitative risk estimates are based on the conservative assumption that an individual is exposed to multiple COPCs by multiple exposure pathways. In accordance with USEPA guidance, chemical- and pathway-specific risks are summed to provide estimates of total risk for a given receptor. Risk estimates are developed by integrating the chemical intake levels with chemical-specific toxicity factors. Risk assessment calculations are contained in Appendix E-1 and example calculations are provided in Appendix E-2.

Incremental Lifetime Cancer Risk (ILCR) estimates are generated for each COPC using estimated exposure intakes and published CSFs, as follows:

$$\text{ILCR} = \text{Estimated Exposure Intake} \times \text{CSF}$$

An ILCR of 1×10^{-6} indicates that the exposed receptor has a one-in-one-million chance of developing cancer under the defined exposure scenario. Alternatively, such a risk may be interpreted as representing one additional case of cancer in an exposed population of one million persons.

Noncarcinogenic risks are assessed using the concept of HQs and HIs. The HQ for a COPC is the ratio of the estimated intake to the RfD, as follows:

$$\text{HQ} = (\text{Estimated Exposure Intake}) / (\text{RfD})$$

An HI for a given exposure route is generated by summing the individual HQs for all COPCs. The HI is not a mathematical prediction of the severity of toxic effects and is therefore not a true risk. It is simply a numerical indicator of the possibility of the occurrence of noncarcinogenic (threshold) effects.

6.6.1 Comparison of Quantitative Risk Estimates to Benchmarks

To interpret the quantitative risks and to aid risk managers in determining the need for remediation at a site, quantitative risk estimates are compared to typical benchmarks. The USEPA has defined the range of 10^{-4} to 10^{-6} as the ILCR target range for hazardous waste facilities addressed under CERCLA and RCRA. While USEPA guidance will allow higher concentrations reflected in the 1×10^{-4} to 1×10^{-6} site risk range, Mississippi is a state that utilizes a 1×10^{-6} risk level. Therefore, individual or cumulative ILCRs greater than 1×10^{-6} are considered to be "unacceptable" by the MDEQ.

An HI exceeding unity (1) indicates that there may be potential noncarcinogenic health risks associated with exposure. If an HI exceeds unity, target organ effects associated with exposure to COPCs are segregated (and the HI is calculated on a target organ/target effect basis). Only those chemicals that affect the same target organ(s) or exhibit similar critical effect(s) are regarded as truly additive. Consequently, it may be possible for a cumulative HI to exceed 1.0, but no adverse health effects are anticipated if the COPCs do not affect the same target organ or exhibit the same critical effect. Individual target organ HIs for all receptors are presented in the RAGS Part D tables (Table 9s) presented in Appendix E-1.

6.6.2 Risk Assessment Results

The baseline HHRA conducted for Site 1 evaluates the risks potentially incurred by site maintenance workers, industrial workers, construction/excavation workers, adult and adolescent trespassers, and hypothetical future residents. All potential receptors were evaluated for exposure to COPCs in soil, surface water, and sediment. Construction/excavation workers and residents were also evaluated for exposure to groundwater. Both RME and CTE exposure scenarios were evaluated. Tables 6-20 and 6-21 contain a summary of the estimated risks for Site 1 for the RME and CTE, respectively. Calculations of the detailed, chemical-specific risks for Site 1 are included in Appendix E-1. The following sections discuss the results of the risk characterization.

6.6.2.1 Carcinogenic Risks - RME

Quantitative estimates of carcinogenic effects are presented in the form of ILCRs. The target risk benchmark for carcinogenic effects, as defined by the MDEQ, is 1×10^{-6} . Estimated ILCRs for Site 1 are discussed in the following subsections. The carcinogenic risks calculated for the RME case are summarized in Table 6-20.

The ILCR for the construction worker and adult trespasser were less than the MDEQ's risk management benchmark (1×10^{-6}) and less than USEPA target risk range of 10^{-4} to 10^{-6} .

The ILCRs for the site maintenance worker, site industrial worker, and the adolescent trespasser all slightly exceeded the MDEQ risk benchmark of 1×10^{-6} (total ILCRs were 2×10^{-6} , 7×10^{-6} , and 2×10^{-6} , respectively) but were well within the USEPA target range of 10^{-4} to 10^{-6} . Dieldrin in surface soil and Aroclor-1242 in subsurface soil for the industrial worker were the only individual chemicals to have risk estimates exceeding 1×10^{-6} .

The total ILCRs for hypothetical future residents (adult and child ILCRs both = 3×10^{-4}) and lifelong residents (ILCR = 5×10^{-4}) exceed the MDEQ goal for cumulative site risk (1×10^{-6}) and the USEPA's target risk range of 10^{-4} to 10^{-6} when estimated for monitoring well groundwater and soil, surface water, and sediment. Adult and child total ILCRs were each 1×10^{-5} and when estimated for DPT groundwater, soil, surface water, and sediment; the lifelong resident ILCR was 5×10^{-5} for these media. The elevated residential risk is primarily due to exposure to arsenic in groundwater via the ingestion pathway. To a lesser extent, tetrachloroethene, dieldrin, arsenic, and Aroclor-1242 in soils contribute risk to the residential receptors; these chemicals have individual risks that are less than or equal to 10^{-6} .

The chemical-specific risks are presented in the RAGS-Part D tables located in Appendix E-1.

6.6.2.2 Noncarcinogenic Effects - RME

Quantitative estimates of noncarcinogenic (toxic) effects are presented in the form of HQs and HIs. As discussed above, the risk benchmark for HQs and HIs (calculated on a target organ specific basis) is 1 (USEPA, 1989). Estimated HQs and HIs for Site 1 are discussed below.

Cumulative HIs for construction/excavation workers, site maintenance workers, site industrial workers, adolescent trespassers, and adult trespassers under the RME scenario were less than unity (1), indicating that no toxic effects are anticipated for these receptors under the defined exposure conditions.

Cumulative HIs for the future adult and child residents were 20 and 6, respectively. Primary contributors to the residential HIs were arsenic, iron, and thallium in groundwater for both receptors and manganese in groundwater for the child resident only. Risk estimates calculated for ingestion exceeded those calculated for the dermal and inhalation routes of exposure.

The HIs for exposure to soil, surface water, and sediment were less than unity for all receptors.

6.6.3 CTE Evaluation

As discussed in Section 6.4.3, an evaluation of the potential risks associated with the CTE scenario is included to provide a measure of the central or average case exposure. Summaries of the estimated risks for the CTE scenarios are contained in Table 6-21.

6.6.3.1 Carcinogenic Risks - CTE

The ILCRs for construction/excavation workers, site maintenance workers, and both adolescent and adult trespassers were less than the MDEQ goal for cumulative site risk (1×10^{-6}). The site industrial worker had a total ILCR equal to 1×10^{-6} and thus did not exceed the MDEQ target cancer risk benchmark.

All the residential receptors had ILCRs exceeding both the MDEQ goal (1×10^{-6}) and the USEPA target range of 1×10^{-4} to 1×10^{-6} with estimated ILCRs of 2×10^{-5} , 4×10^{-5} , and 6×10^{-5} respectively for the child, adult, and lifelong hypothetical resident receptors when exposed to monitoring well groundwater, soil, sediment, and surface water. Risks were less for the same receptors when estimated for DPT groundwater, soil, sediment, and surface water (2×10^{-6} , 1×10^{-6} , and 3×10^{-6} respectively). The elevated residential risk is primarily due to exposure to ingestion of arsenic in groundwater.

6.6.3.2 Noncarcinogenic Effects - CTE

Target organ-specific HIs for construction/excavation workers, site maintenance workers, site industrial workers, adolescent trespassers, and adult trespassers under the CTE scenario were less than unity (1), indicating that no toxic effects are anticipated for these receptors under the CTE exposure conditions.

The HIs for both the child and adult residents exceeded unity on a target organ-specific basis. Total HIs were 6 and 3 for the child and adult residents, respectively for monitoring well groundwater, soil, sediment, and surface water. The primary chemicals contributing to the elevated residential noncarcinogenic risks were arsenic, iron, and thallium through groundwater ingestion.

6.7 UNCERTAINTY ANALYSIS

The baseline HHRA for Site 1 was performed in accordance with current USEPA guidance. However, there are varying degrees of uncertainty associated with the baseline HHRA. This section presents a brief summary of uncertainties inherent in the risk assessment and includes a discussion of how they may affect the quantitative risk estimates and conclusions of the risk analysis.

6.7.1 General Uncertainty in Risk Assessment

Uncertainty in the selection of COPCs is related to the current status of the predictive databases, the grouping of samples, and the procedures used to include or exclude constituents as COPCs. Uncertainty associated with the exposure assessment includes the values used as input variables for a given intake route or scenario, the assumptions made to determine EPCs, and the predictions regarding future land use and population characteristics. Uncertainty in the toxicity assessment includes the quality of the existing toxicity data needed to support dose-response relationships and the weight-of-evidence used to determine the carcinogenicity of COPCs. Uncertainty in risk characterization includes that associated with exposure to multiple chemicals and the cumulative uncertainty from combining conservative assumptions made in earlier steps of the risk assessment process.

Whereas there are various sources of uncertainty, the direction of uncertainty can be influenced by the assumptions made throughout the risk assessment, including selection of COPCs and selection of values for dose-response relationships. To account for uncertainties in the development of a risk assessment, conservative estimates must be made to make sure that the particular assumptions made are protective of sensitive subpopulations and the maximum exposed individuals. Therefore, throughout the entire risk assessment, assumptions that consider safety factors are made so that the final calculated risks are overestimated, and consequentially, very conservative.

The major sources of uncertainty associated with this risk assessment are discussed below.

6.7.2 Uncertainty in Selection of COPCs

A minor amount of uncertainty is associated with the selection of COPCs that may affect the numerical risk estimates presented in the risk assessment. The most significant issues related to uncertainty in COPC selection are the existing database (i.e., the use of validated or unvalidated sample results), the inclusion of chemicals potentially attributable to background, the screening levels that are used, the exclusion of historical data from the risk assessment, and the absence of screening levels for a few chemicals detected in the site media. A brief discussion of each of these issues is provided in the remainder of this section.

6.7.2.1 Existing Databases

The data used in the risk assessment for Site 1 were obtained from samples collected as part of the field efforts performed by TtNUS in 2008. No historical data were used for risk assessment purposes. All analytical data were validated according to the methodologies specified in the Work Plan (TtNUS, 2009). The qualification of data during the formal data validation process is not expected to compromise the results of the HHRA. Analytical data qualified as estimated were utilized, even though the reported positive concentrations or sample-specific quantitation limits may be somewhat imprecise. The use of estimated data adds to the uncertainty associated with the risk assessment. However, the associated uncertainty is expected to be negligible compared to the other uncertainties inherent in the risk evaluation process (i.e., uncertainties with land uses, exposure scenarios, toxicological criteria, etc.). Analytical data qualified for blank contamination were used in the baseline risk assessment. When determining exposure concentrations via statistical procedures, chemicals not detected were conservatively assumed to be present at concentrations equal to one-half the sample-specific quantitation limits. Analytical results for some chemicals qualified "R," unreliable, were not used in the risk assessment.

6.7.2.2 Exclusion of Historical Data from the Risk Assessment

Data collected from the most recent sampling events by TtNUS in 2008, were used to evaluate potential risks for Site 1. Historical data collected for soil, groundwater, surface water, and sediment investigations were not used in this assessment. This is because the historical data was more than 10 years old and did not meet current standards for methods and reporting limits.. Exclusion of the historical data from the risk assessment may result in uncertainty in the COPC selection and in the exposure concentrations used to quantitate risks. However, since the most recent data were used to assess risks, the uncertainty associated with the omission of historical data should be minimal, and conclusions of the risk assessment were probably not affected by the exclusion of the historical data from the risk assessment.

6.7.2.3 Chemicals Potentially Attributable to Background

No chemicals in soil, surface water, or sediment were eliminated as COPCs on the basis of background. This is an important consideration when interpreting the results of the HHRA for Site 1 because arsenic was identified as a risk driver in soils and sediment. As indicated previously, some of the sample concentrations of arsenic in soil and groundwater are also within naturally occurring levels in Mississippi and in the U.S. The inclusion of some metals present at background concentrations in the quantitative risk evaluation can contribute to the overestimation the risks. Several metals selected as COPCs in soil were within published background ranges in literature (see Sections 6.3.2 and 6.3.3). For example, estimated ILCRs for arsenic in surface and subsurface soil exceeded 1×10^{-6} , the MDEQ target risk threshold, for the hypothetical lifelong resident. However, if the risks due to arsenic are excluded, the ILCRs for these media would still exceed 1×10^{-6} due to the presence of organic COPCs.

Several upgradient wells were used as background locations for the groundwater datasets. However, no groundwater chemicals were eliminated from COPC selection on the basis of background. Therefore, no uncertainty is introduced through eliminating chemicals detected in groundwater by means of a background screen. However, in the case of the monitoring well samples, only one upgradient sample (01GW2301) provided background data. Therefore, the background dataset is very small, and only a maximum concentration comparison between site data and the background data sample could be conducted. The use of a more robust background dataset might have affected the outcome of the background screen. As previously mentioned, per the scientific literature consulted, arsenic, iron, and manganese concentrations detected in the site monitoring wells are within the concentration range typically found in groundwater (Dragun, 1988).

It was also previously noted that tetrachloroethene was detected in the upgradient (background) monitoring well sample (01GW2301) but was not detected in any of the non-background monitoring well samples. The positive detection of tetrachloroethene in the background sample (2.5 ug/L) does exceed the ORNL screening level for tetrachloroethene in tap water of 0.11 ug/L. The estimated ILCR based on this concentration is approximately 2×10^{-5} ($(2.5 \text{ ug/L}) / (0.11 \text{ ug/L}) * 1 \times 10^{-6}$). However, the concentration of tetrachloroethene in the background sample does not exceed the MCL/Mississippi TRG for groundwater of 5 ug/L.

Trichloroethene was detected at Site 1 in the background monitoring well sample at a concentration of 1.3 ug/L, which is less than the ORNL RSL for tap water. Therefore, trichloroethene would not have been selected as a COPC for the direct contact pathway even if the upgradient well sample had been included in the Site 1 data set.

Risks due to background concentrations as discussed above have considerable uncertainty because it is unknown if the contamination represented in the upgradient well is due to another source unrelated to Site 1. Also, tetrachloroethene was not detected in any of the 21 monitoring well samples used to represent Site 1 and trichloroethene was only detected in 1 of the 21 site (non-background) samples.

6.7.2.4 COPC Screening Levels

The use of risk-based screening levels for soil and groundwater based on conservative residential land use scenarios corresponding to an ILCR of 10^{-6} and HI of 0.1 should make certain that the significant contributors to risk from a site are evaluated. The elimination of chemicals that are present at concentrations that correspond to an ILCR less than 10^{-6} and an HI less than 0.1 should not affect the final conclusions of the risk assessment because these chemicals are not expected to cause a potential health concern at the concentrations detected.

6.7.2.5 Absence of COPC Screening Levels

Because of the lack of toxicity criteria, ORNL RSLs and MDEQ Tier 1 TRGs are not available for calcium, magnesium, sodium, and potassium. This may lead to a slight underestimation of potential risks. However, these inorganics are essential nutrients, commonly detected in environmental media, and receptor risks should not be underestimated due to excluding these nutrients from COPC selection.

Risk-based screening levels are also currently not available for several organic constituents detected at Site 1 (i.e., phenanthrene, alpha- and gamma-chlordane, delta-BHC, endosulfan II, endosulfan sulfate, and endrin aldehyde). Therefore, screening levels available for surrogate chemicals were used as screening levels for these constituents. In the COPC selection for Site 1, the screening level for pyrene was used as a surrogate for phenanthrene, chlordane was used as a surrogate for alpha- and gamma-chlordane, alpha-BHC was used as a surrogate for delta-BHC, endosulfan was used as a surrogate for endosulfan II and endosulfan Sulfate, and endrin was used as a surrogate for endrin aldehyde. The use of these surrogates may increase the uncertainty in the risk assessment. The direction of bias cannot be determined.

6.7.3 Uncertainty in the Exposure Assessment

Uncertainty in the exposure assessment arises because of the methods used to calculate EPCs, the determination of land use conditions, the selection of receptors and scenarios, and the selection of exposure parameters. Each of these is discussed below.

6.7.3.1 Uncertainty in the Elimination of Exposure Routes/Pathways

Potential risks were evaluated for all environmental media sampled at Site 1. Surface water and sediment were evaluated for ingestion and dermal contact. Inhalation of volatiles from surface water and sediment was not evaluated because potential risks from inhalation are expected to be minimal for these media. In addition, predictive models are currently not available for these scenarios. The omission of these exposure pathways/routes may result in an underestimation of total risks for the site, but the underestimation is expected to be minimal when compared to risks for other media and exposure routes.

6.7.3.2 Exposure Point Concentrations

Uncertainty is associated with the use of the 95 percent UCL on the mean concentration as the EPC. As a result of using the 95 percent UCL, the estimations of potential risk are most likely to be overestimated because this is a representation of the upper limit that potential receptors would be exposed to over the entire exposure period. In some cases (e.g., surface water and sediment), the maximum concentration was used as the EPC because the dataset contained less than 10 samples. The maximum concentration is also used when the UCL is greater than the maximum concentration. The use of the maximum concentration as the EPC tends to overestimate potential risks because receptors are assumed to be exposed continuously to the maximum concentration for the entire exposure period, which is unlikely. EPCs for groundwater were also maximum concentrations, as no contaminant plume was well defined in the groundwater samples from Site 1. The maximum detected concentration was also used as the EPC for the COPCs selected in subsurface soil, surface water, and sediment because these datasets contained fewer than 10 samples. This is an important consideration for Aroclor-1242 in subsurface soil, which was a risk driver for the industrial worker and the residents (child/adult/lifelong). As a result, the industrial worker and residential risks due to this chemical are likely overestimated.

Uncertainty is also introduced when the nondetects are assigned a value of one-half the quantitation limit when calculating the EPC. This may either overestimate or underestimate the risks to potential receptors.

6.7.3.3 Land Use

Uncertainty and conservatism may be introduced into the risk assessment when estimated risks are not based on current land use patterns. The risks calculated in this HHRA are based on current and projected land use at NCBC. Site 1 is currently used as a training facility, and the site is expected to be used for this purpose in the future. Access to the site is not restricted and adolescents have the potential to play on the site. For this reason, trespassers (adolescent and adult) were evaluated in the risk assessment and were assumed to be exposed to site media for 30 days per year in the RME scenario and 15 days per year in the CTE scenario. However, an additional consideration is that if the landfill area is capped in

the future, the pathway is no longer complete for receptor exposure to chemicals in the soils contained under the cap. Much of the uncertainty in this risk assessment is related to groundwater usage (the elevated risks calculated for Site 1 are mainly due to exposure to groundwater). The risk assessment assumes that groundwater is used as a source of domestic drinking water. However, the groundwater is not currently used for this purpose, and it is unlikely that groundwater at the site would be used as a source of potable water in the future. The land use controls in place at Site 1 are expected to ensure that no wells will be installed on the site for domestic or commercial purposes in the future as well. The hypothetical residential receptors were evaluated mainly for the purpose of decision making because it is unlikely that the future land use of Site 1 will become residential. However, as stated in the work plan, it is possible that areas adjacent to Site 1 could be used as residential areas. The plausible future "off-site" residential scenario was evaluated using the future on-site residential exposure factors. Thus, the residential scenario should overestimate risks to potential future off-site residents.

6.7.3.4 Exposure Parameters

Each exposure factor selected for use in the risk assessment contains some associated uncertainty. Generally, exposure factors are based on surveys of physiological and lifestyle profiles across the United States. The attributes and activities studied in these surveys generally have a broad distribution. To avoid underestimation of exposure, USEPA guidelines (e.g., USEPA, 1991b) for the RME receptor were used, if applicable, which generally specify the use of the 95th percentile for most parameters. Therefore, the selected exposure factors for the RME receptor represent the upper bound of the observed or expected practices which are characteristic of the majority of the population. Because the USEPA does not provide values for exposure factors for some receptors/pathways, professional judgment is used to determine some values. When using professional judgment, an effort was made to be reasonably conservative. However, the use of professional judgment adds uncertainty to the risk assessment.

Generally, uncertainty can be assessed for many assumptions made in determining factors for calculating exposures and intakes. Many of these parameters were determined from the statistical analyses of human population characteristics. Often, the database used to summarize a particular exposure parameter (i.e., body weight) is quite large. Consequently, the values chosen for such variables in the RME scenario have low uncertainty. For many parameters for which limited information exists (e.g., dermal absorption), greater uncertainty exists. For example, current USEPA guidance (USEPA, 2004c) does not provide dermal absorption factors for exposure to most metals (except arsenic and cadmium) and VOCs in soil. Therefore, risks for dermal contact with soil are not evaluated for metals other than arsenic and cadmium. Consequently, risks from exposure to soil may be underestimated by omitting metals from the dermal risk assessment (no VOCs were selected as COPCs in soil).

6.7.3.5 Uncertainty Associated with the Johnson and Ettinger Model

As discussed in Section 6.4.5.2, exposures by hypothetical residents to COPCs that may migrate from groundwater into indoor air were evaluated with USEPA's Johnson and Ettinger volatilization model (USEPA, 2004b). The results of the vapor intrusion evaluation are not included in the quantitative risk assessment presented in Section 6.6.2 because of the uncertainty associated with the air concentrations generated using the Johnson and Ettinger Model. Results of the evaluation and uncertainties associated with the risks are presented in Table 6-22 and discussed in the following paragraphs. The model results are also included as Appendix E-3.

Trichloroethene was the only COPC selected for the vapor intrusion pathway. The estimated ILCR for residential receptors was 1×10^{-7} , which is less than the MDEQ goal for total site risk of 1×10^{-6} . The EPC used in the risk modeling was 0.32 ug/L.

Although they were not evaluated in this HHRA, HIs and ILCRs for industrial workers would be expected to be within acceptable levels because these receptors would be exposed to volatiles in indoor air on a less frequent basis than residential receptors. In addition, industrial facilities are typically larger than residential housing units and have larger air exchange rates, which would result in lower indoor air concentrations.

The results of the vapor intrusion modeling are subject to the following sources of uncertainty:

- Site-specific parameters were used in the model whenever possible. For example, site-specific values were used for depth to the water table and soil type. Model default values for soil bulk density and soil porosity were found to be within the range of values measured at the site and were used in model calculations. Site-specific values for building dimensions, soil-building pressure differential, seam crack width, and air-exchange rates were not available. Therefore, model default values were used for these parameters. Model default values were also used for residential dwelling dimensions based on owner-occupied and rental single-family detached residences in the United States. The use of model default values tends to increase the uncertainty in the calculated risks. The direction of the uncertainty is not known, although the model default values are generally conservative and tend to overestimate air concentrations. The default model air-exchange rate (0.45 per hour) was used to evaluate residential risks. As discussed in the model guidance, this air-exchange rate was based on typical residential building dimensions and ventilation rates.
- The default building parameters for the Johnson and Ettinger Model assume that the dimensions of buildings and ventilation rates are typical of residential dwellings in the United States. These

include an air exchange rate of 0.45 per hour and residential building dimensions of 961 centimeters (cm) long by 961 cm wide by 488 cm high (approximately 16,000 cubic feet).

- The model assumes an infinite source and does not take into account transformation processes such as biodegradation, which increased the conservatism of this assessment.

6.7.3.6 Uncertainty Associated with the VDEQ Model for Exposure to Vapors in a Trench

As discussed in Section 6.4.5.2, exposure of construction workers to vapors in a trench was evaluated by a vadose zone model recommended by the Virginia Department of Environmental Quality (VDEQ) to estimate volatilization of gases from contaminated groundwater into a trench. Site-specific parameters, such as groundwater concentrations were used in the model, if possible. However, it was necessary to use model default values for most of the input parameters. The use of model default values tends to increase the uncertainty in the calculated risks. The direction of the uncertainty was not known. One of most sensitive parameters, in terms of potential risk, is the air-exchange rate (ACH) in the trench which was based on assumed trench dimensions (i.e., the ratio of trench width to depth). The risk assessment assumed that air exchange between the trench and above-ground atmosphere was not restricted (as opposed to a confined space) and may tend to underestimate risks. However, note that the model only gives the user two choices regarding the value of ACH, a very confined space which tends to greatly overestimate air concentrations in the trench or a less restricted space which results in lower air concentrations. The difference in vapor concentrations in a trench based on the two different ACHs is approximately 2 to 3 orders of magnitude. A detailed discussion of determination of the ACH is presented in Section 6.4.5.2.

6.7.3.7 Uncertainty Associated with Contamination Hot Spots

According to the Site 1 work plan, human health risks at Site 1 were expected to be low except for “hot spot” areas of concentrated contamination. Evidence in the surface soil data indicates that a hot spot of contamination may exist for dieldrin at Site 1. Dieldrin was a carcinogenic risk driver in surface soil for the industrial worker and residential (child/adult/lifelong) receptors. Dieldrin was detected in 8 of 20 surface soil samples at Site 1 with a maximum concentration of 460 ug/kg at sample location 01SS025. However, the second greatest concentration of dieldrin in surface soil was 15 ug/kg at sample location 01SS10, which is less than both restricted and unrestricted MDEQ screening criteria (358 ug/kg and 39.9 ug/kg, respectively) as well as the ORNL residential soil RSL (30 ug/kg). Therefore, dieldrin would not have been selected as a COPC if the sample result from location 01SS025 had not been included in the dataset. Dieldrin was not selected as a COPC in subsurface soil. It is likely that the risks due to dieldrin in surface soil are overestimated.

6.7.3.8 Uncertainty Associated with Groundwater Inhalation Exposures

In compliance with Region IV guidance, the groundwater ingestion values were used as the inhalation intake values. The RME exposure parameters used in this HHRA assumed that child and adult residents would ingest 1.5 and 2.0 L of groundwater per day, respectively. Using ingestion exposures as inhalation exposures is extremely conservative because it is unlikely that residents would intake the same chemical concentration from inhalation (during showering/bathing, etc.) as they would through ingestion.

Tetrachloroethene was a primary risk driver in groundwater for both child and adult residents primarily through inhalation. It is likely that residential inhalation of groundwater risks are overestimated as a result of the extremely conservative exposure intake values used.

6.7.4 Uncertainty in the Toxicological Evaluation

Uncertainties associated with the toxicity assessment (determination of RfDs and CSFs and use of available criteria) are presented in this section.

6.7.4.1 Derivation of Toxicity Criteria

Uncertainty associated with the toxicity assessment is associated with hazard assessment and dose-response evaluations for the COPCs. The hazard assessment deals with characterizing the nature and strength of the evidence of causation or the likelihood that a chemical that induces adverse effects in animals will also induce adverse effects in humans. Hazard assessment of carcinogenicity is evaluated as a weight-of-evidence determination, using the USEPA methods. Positive animal cancer test data suggest that humans contain tissue(s) that may manifest a carcinogenic response; however, the animal data cannot necessarily be used to predict the target tissue in humans. In the hazard assessment of noncancer effects, however, positive animal data often suggest the nature of the effects (i.e., the target tissues and type of effects) anticipated in humans.

Uncertainty in hazard assessment arises from the nature and quality of the animal and human data. Uncertainty is reduced when: similar effects are observed across species, strain, sex, and exposure route; the magnitude of the response is clearly dose related; pharmacokinetic data indicate a similar fate in humans and animals; postulated mechanisms of toxicity are similar for humans and animals; and the chemical of concern is structurally similar to other chemicals for which the toxicity is more completely characterized.

Uncertainty in the dose-response evaluation includes the determination of a CSF for the carcinogenic assessment and derivation of an RfD or reference concentration (RfC) for the noncarcinogenic

assessment. Uncertainty is introduced from interspecies (animal to human) extrapolation which, in the absence of quantitative pharmacokinetic or mechanistic data, is usually based on consideration of interspecies differences in basal metabolic rate. Uncertainty also results from intraspecies variation. Most toxicity experiments are performed with animals that are very similar in age and genotype, so intragroup biological variation is minimal, but the human population of concern may reflect a great deal of heterogeneity including unusual sensitivity or tolerance to the COPC. Even toxicity data from human occupational exposures reflect a bias because only those individuals sufficiently healthy to attend work regularly (the "healthy worker effect") and those not unusually sensitive to the chemical are likely to be occupationally exposed. Finally, uncertainty arises from the quality of the key study from which the quantitative estimate is derived and the database. For cancer effects, the uncertainty associated with dose-response factors is mitigated by assuming the 95 percent upper bound for the CSF. Another source of uncertainty in carcinogenic assessment is the method by which data from high doses in animal studies are extrapolated to the dose range expected for environmentally exposed humans. The linearized multistage model, which is used in nearly all quantitative estimations of human risk from animal data, is based on a nonthreshold assumption of carcinogenesis. Evidence suggests, however, that epigenetic carcinogens, as well as many genotoxic carcinogens, have a threshold below which they are noncarcinogenic. Therefore, the use of the linearized multistage model is conservative for chemicals that exhibit a threshold for carcinogenicity.

For noncancer effects, additional uncertainty factors may be applied in the derivation of the RfD or RfC to mitigate poor quality of the key study or gaps in the database. Additional uncertainty for noncancer effects arises from the use of an effect level in the estimation of an RfD or RfC, because this estimation is predicated on the assumption of a threshold below which adverse effects are not expected. Therefore, an uncertainty factor is usually applied to estimate a no-effect level. Additional uncertainty arises in estimation of an RfD or RfC for chronic exposure from subchronic data. Unless empirical data indicate that effects do not worsen with increasing duration of exposure, an additional uncertainty factor is applied to the no-effect level in the subchronic study. Uncertainty in the derivation of RfDs is mitigated by the use of uncertainty and modifying factors that normally range between 3 and 10. The resulting combination of uncertainty and modifying factors may reach 1,000 or more.

The derivation of dermal RfDs and CSFs from oral values may cause uncertainty. This is particularly the case when chemical-specific gastrointestinal absorption rates are not available in the literature or when only qualitative statements regarding absorption are available.

6.7.4.2 Uncertainty Associated with Evaluation of the Dermal Exposure Pathway

According to RAGS-Part E (USEPA, 2004c), risks from dermal absorption from soil are to be quantitatively evaluated for arsenic, cadmium, chlordane, 2,4-dichlorophenoxyacetic acid, DDT, TCDD (and other

dioxins), PAHs, PCBs, pentachlorophenol, and SVOCs because of the limited guidance available to estimate dermal absorption factors for other constituents. Therefore, the dermal route of exposure is evaluated quantitatively for these chemicals only. Risks for dermal exposure to metals (other than arsenic and cadmium) and VOCs identified as COPCs for soil or sediment were not quantified in the risk assessment. Consequently, potential risks may be underestimated by excluding these constituents from the dermal risk assessment calculations. The uncertainty is reduced somewhat by the fact that no VOCs were identified as COPCs for soil or sediment at Site 1.

Dermal risks were calculated using a USEPA model presented in RAGS-Part E (USEPA, 2004c) which, according to the guidance, tends to overestimate intakes and risks for dermal contact for some chemicals (e.g., PAHs, PCBs, and dioxins). Appendices A and B of RAGS-Part E discuss the uncertainties in the permeability coefficients for these chemicals and the limitations of the dermal absorption model when evaluating chemicals.

6.7.4.3 Uncertainty Associated with Evaluation of Arsenic

Arsenic is a primary risk driver for residential exposure to groundwater at Site 1. Arsenic was detected in only 2 of 21 groundwater samples. The only two positive detections for arsenic in the dataset (14.2 µg/L and 19.1 µg/L) exceed the MCL (10 µg/L) but do not exceed the adopted Mississippi groundwater criteria (50 µg/L). Note that the risk estimate calculated assuming exposure to the MCL results in a cancer risk greater than 1×10^{-4} . In addition, the range of arsenic concentrations detected in groundwater samples (3.3 – 11.4 ug/L) is within the range of naturally occurring levels in the United States reported in the literature (less than 1.0 – 30 ug/L) (Dragun, 1988).

There is uncertainty associated the evaluation of arsenic as a carcinogen. Although the more restrictive basis for evaluating risk associated with exposure to arsenic is to assume it is a carcinogen, carcinogenic effects are not the primary health effects expected to be manifested on exposure to arsenic. Scientific information indicates that humans are capable of metabolizing arsenic to expedite its elimination from the body (ATSDR, 1997). Its elimination from the body obviously mitigates the possibility for arsenic to manifest carcinogenic effects. Therefore, evaluating arsenic as a noncarcinogen would be more appropriate. However, arsenic was conservatively evaluated as a carcinogen in this risk assessment. Consequently, risks for this chemical are probably overestimated to some degree.

In addition to the uncertainty associated with the metabolism of arsenic, there is also uncertainty associated with the bioavailability of arsenic. The risks estimates calculated for arsenic as based on the assumption that 100 percent of the arsenic that enters the body is bioavailable. However, the toxicity studies on which RfDs and CSFs for metals are based do not account for the characteristics of a metal in soil or the limitations that these characteristics place on the absorption of the metal. Several recent

studies on the bioavailability of arsenic (Ruby, V. et al., 1999) indicate that the bioavailability of arsenic in various soil types ranges from 8 to 28 percent. Based on these studies, it is possible that the risks calculated for arsenic in soil could be overestimated by as much as one order of magnitude.

6.7.4.4 Use of Iron Toxicity Criteria

A RfD published in the report Provisional Peer Reviewed Toxicity Values for Iron and Compounds (USEPA, 2006) was used to evaluate noncarcinogenic effects from exposure to iron. Iron is an essential element, and individual reactions to iron may be highly variable; therefore, there is some degree of uncertainty associated with the use of the RfD. The iron HQ for the child resident assumed to be exposed to groundwater was 6. As mentioned previously, the maximum concentration of iron in groundwater is within the typical range for groundwater in published scientific literature.

6.7.5 Uncertainty in the Risk Characterization

Uncertainty in risk characterization results primarily from assumptions made regarding additivity of effects from exposure to multiple COPCs from various exposure routes. High uncertainty exists when summing cancer risks for several substances across different exposure pathways. This assumes that each substance has a similar effect and/or mode of action. Often compounds affect different organs, have different mechanisms of action, and differ in their fate in the body, so additivity may not be an appropriate assumption. However, the assumption of additivity is made to provide a conservative estimate of risk.

Finally, the risk characterization does not consider antagonistic or synergistic effects. Little or no information is available to determine the potential for antagonism or synergism for the COPCs. Therefore, the uncertainty regarding antagonistic or synergistic effects is ambiguous because potential human health risks may either be underestimated or overestimated.

6.8 SUMMARY AND CONCLUSIONS

Site 1, the Disaster Recovery Disposal Area, is a former landfill located north of 7th Street and east of Colby Avenue and is currently used as a mock disaster training facility. The landfill was operated from 1942 until 1948. Waste material was disposed of in trenches, burned daily, and then backfilled. During the time this landfill was operated, nearly all of the solid waste and some of the liquid/chemical waste generated at NCBC Gulfport was disposed of at this site. In addition, some waste fuel, oil, solvents, paint, and paint thinners, all of which were reportedly containerized in 55-gallon drums, were transported to the site and buried in trenches (Envirodyne, 1985). Access to the site is not restricted and adolescents can potentially play at the site.

Site maintenance workers, industrial workers, construction/excavation workers, adult trespassers, adolescent trespassers, and hypothetical future residents were evaluated as potential receptors in the site-specific baseline HHRA. All receptors were evaluated for potential exposure to COPCs in surface soil, subsurface soil, surface water, and sediment. Construction/excavation workers and hypothetical future residents were also evaluated for exposure to COPCs in groundwater, and future residents were also evaluated for vapor intrusion into indoor air.

Inhalation of volatile emissions from soil and fugitive dust was evaluated qualitatively via a comparison of site data with USEPA Generic SSLs for transfers from soil to air (inhalation). Exposure was considered to be relatively insignificant because maximum soil concentrations for all detected chemicals were less than the inhalation SSLs and this pathway was not quantitatively evaluated in the HHRA.

The following chemicals were identified as COPCs for quantitative risk evaluation at Site 1:

- Surface Soil – dieldrin, aluminum, antimony, arsenic, cobalt, iron, manganese
- Subsurface soil – Aroclor-1242, aluminum, arsenic
- Groundwater –
 - DPT samples: tetrachloroethene
 - Monitoring well samples: naphthalene, aluminum, arsenic, iron, manganese, thallium
- Surface Water – arsenic, iron
- Sediment – benzo(a)pyrene equivalents, aluminum, arsenic, iron, manganese

Risk Assessment Results – Current Land Use

Under current land use, quantitative estimates of noncarcinogenic and carcinogenic risks (HIs and ILCRs, respectively) were developed for site maintenance workers, industrial workers, and trespassers hypothetically exposed to COPCs in surface soil, subsurface soil, surface water, and sediment. Total ILCRs for adult trespassers were less than or equal to the MDEQ goal for cumulative site risk (1×10^{-6}). Total noncarcinogenic HIs for site maintenance workers, industrial workers, and adolescent and adult trespassers were less than unity indicating that no adverse toxic effects are expected under the conditions established in the exposure assessment.

Cancer risk estimates developed for site maintenance workers, industrial workers, and adolescent trespassers exceeded USEPA and state of Mississippi cancer risk benchmarks. The noncancer benchmark

was not exceeded for these receptors. The ILCRs exceeded 1×10^{-6} and were primarily due to dieldrin and PCBs in soil for the industrial worker and arsenic in soil for the adolescent trespasser.

Risk Assessment Results – Future Land Use

Under future land use, quantitative estimates of noncarcinogenic and carcinogenic risks (HIs and ILCRs, respectively) were developed for site maintenance workers, industrial workers, construction/excavation workers, trespassers, and hypothetical future residents.

Risk assessment results for site maintenance workers, industrial workers, and trespassers are the same as those described above.

Total ILCRs for future construction/excavation workers were less than the MDEQ goal for cumulative site risk (1×10^{-6}), and total HIs for construction/excavation workers were less than unity, indicating that no adverse toxic effects are expected for exposure to soil, groundwater, surface water, and sediment for this receptor under the defined exposure conditions.

Cancer and non-cancer risk estimates developed for the hypothetical future resident exceeded USEPA and state of Mississippi cancer and non-cancer risk benchmarks. The ILCR for hypothetical future residents exceeded 1×10^{-4} and is primarily due to exposure to arsenic (via ingestion) in groundwater. The cumulative noncarcinogenic HI for future residents exceeded the USEPA goal of unity and is mainly the result of exposure to arsenic, iron, and thallium in groundwater as well as manganese in groundwater for the child resident. In addition, maximum detected concentrations of iron, manganese, and thallium exceeded groundwater USEPA MCLs and MDEQ primary TRGs. However, as discussed in Section 6.6.2, there are significant uncertainties associated with the risk estimates developed for COPCs in groundwater. Among these are the facts that the residential groundwater scenario assumes that groundwater on the site is used as a source of domestic drinking water and ingestion intake values are used to estimate inhalation intake. ILCRs and HIs for residential exposure to surface water for both the adult and child resident and sediment for the adult resident were less than or within USEPA and MDEQ risk benchmarks.

In summary, a HHRA was performed to evaluate exposure to COPCs in subsurface and surface soil, groundwater, surface water, and sediment at Site 1, Disaster Recovery Disposal Area at NCBC, Gulfport. Estimated risks for construction/excavation workers and adult trespassers assumed to be exposed to COPCs in site media were less than or equal to USEPA and MDEQ risk management benchmarks. The quantitative risk evaluation indicated that risk estimates for the site maintenance worker and adolescent trespasser were only marginally greater than the MDEQ benchmark. Additionally, although the total ILCR for the site industrial worker exceeds the MDEQ cancer benchmark, the risk estimate is within one order

of magnitude of the MDEQ benchmark and is primarily due to PCBs and dieldrin in soil, which may be attributable to the limited presence of contamination hot spots.

The quantitative risk evaluation also indicated that potential adverse health effects may be associated with the hypothetical future residential use of groundwater. The maximum detected concentration of tetrachloroethene in groundwater exceeded the ORNL RSL for tap water, and the maximum concentration of arsenic in groundwater exceeded both the ORNL tap water RSL and the MDEQ groundwater TRG. However, there is considerable uncertainty in the risk estimates calculated for exposure to COPCs in groundwater, and the numerical risk results are likely overestimated. In addition, the residential groundwater use scenario is evaluated to be conservative and to provide information to risk managers for Site 1. The groundwater underlying and downgradient of Site 1 is not currently used as a source of drinking water and there are no plans to develop this resource in the future. Residential cancer risk estimates slightly exceeded the MDEQ benchmark for soils (for both adult and child residents) due to dieldrin, arsenic, and PCBs. However, arsenic is within published background levels for soil. Sediment also exceeded the MDEQ cancer benchmark for the child resident only due to arsenic. Residential risks estimated for surface water did not exceed USEPA and MDEQ risk management benchmarks.

**TABLE 6-1
OCCURRENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - DIRECT CONTACT - SURFACE SOIL
SITE 1
NCBC GULFPORT
GULFPORT, MISSISSIPPI
PAGE 2 OF 2**

Scenario Timeframe: Current/Future
Medium: Surface Soil
Exposure Medium: Surface Soil

Footnotes:

- 1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations and as one sample when determining the frequency of detection and average results.
- 2 - Values presented are sample-specific quantitation limits.
- 3 - The maximum detected concentration is used for screening purposes.
- 4 - No site-specific background soil data were available for NCBC Gulfport.
- 5 - Mississippi Department of Environmental Quality (MDEQ), Risk Evaluation Procedures for Voluntary Cleanup and Redevelopment of Brownfield Sites for Unrestricted and Restricted Land Use, February 2002. Noncarcinogenic values are divided by 10.
- 6 - Oak Ridge National Laboratory (ORNL) Regional Screening Level for Residential Soil. The noncarcinogenic values (denoted with a "N" flag) are the screening level divided by 10 to correspond to a target hazard quotient of 0.1. Carcinogenic values represent an incremental cancer risk of 1.0E-06 (carcinogens denoted with a "C" flag) (ORNL, April 2009).
- 7 - USEPA Soil Screening Levels (SSLs). EPA Internet Site at http://risk.lsd.ornl.gov/calc_start.htm.
- 8 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
- 9 - Values are for chlordane.
- 10 - Values are for alpha-BHC.
- 11 - Values are for endosulfan.
- 12 - Values are for endrin.
- 13 - Values are for hexavalent chromium.
- 14 - Ten percent of the noncarcinogenic value is less than the carcinogenic value, therefore the noncarcinogenic is presented.
- 15 - Values are for mercury, inorganic salts.

Definitions:

- C = Carcinogen
- COPC = Chemical Of Potential Concern
- J = Estimated value
- mg/kg = milligrams per kilogram
- µg/kg - micrograms per kilogram
- N = Noncarcinogen
- NA = Not Applicable/Not Available
- S = Concentration may exceed Csat
- sat = soil saturation concentration

Rationale Codes:

- For selection as a COPC:
ASL = Above Screening Level
- For elimination as a COPC:
BSL = Below COPC Screening Level
NUT = Essential nutrient
NTX = No toxicity criteria

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

TABLE 6-3
OCCURRENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - DIRECT CONTACT - SUBSURFACE SOIL
SITE 1
NCBC GULFPORT
GULFPORT, MISSISSIPPI

PAGE 2 OF 2

Footnotes:

- 1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations and as one sample when determining the frequency of detection and average results.
- 2 - Values presented are sample-specific quantitation limits.
- 3 - The maximum detected concentration is used for screening purposes.
- 4 - No site-specific background soil data were available for NCBC Gulfport.
- 5 - Mississippi Department of Environmental Quality (MDEQ), Risk Evaluation Procedures for Voluntary Cleanup and Redevelopment of Brownfield Sites for Unrestricted and Restricted Land Use, February 2002. Noncarcinogenic values are divided by 10.
- 6 - Oak Ridge National Laboratory (ORNL) Regional Screening Level for Residential Soil. The noncarcinogenic values (denoted with a "N" flag) are the screening level divided by 10 to correspond to a target hazard quotient of 0.1. Carcinogenic values represent an incremental cancer risk of 1.0E-06 (carcinogens denoted with a "C" flag) (ORNL, April 2009).
- 7 - USEPA Soil Screening Levels (SSLs). EPA Internet Site at http://risk.lsd.ornl.gov/calc_start.htm.
- 8 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
- 9 - Values are for chlordane.
- 10 - Values are for alpha-BHC.
- 11 - Values are for endosulfan.
- 12 - Values are for endrin.
- 13 - Values are for hexavalent chromium.
- 14 - Ten percent of the noncarcinogenic value is less than the carcinogenic value, therefore the noncarcinogenic is presented.
- 15 - Values are for mercury, inorganic salts.

Definitions:

C = Carcinogen
COPC = Chemical Of Potential Concern
J = Estimated value
mg/kg = milligrams per kilogram
µg/kg - micrograms per kilogram
N = Noncarcinogen
NA = Not Applicable/Not Available
S = Concentration may exceed Csat
sat = soil saturation concentration

Rationale Codes:

For selection as a COPC:
ASL = Above Screening Level
For elimination as a COPC:
BSL = Below COPC Screening Level
NUT = Essential nutrient
NTX = No toxicity criteria

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

**TABLE 6-6
OCCURRENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN - DIRECT CONTACT - GROUNDWATER - MONITORING WELL SAMPLES
SITE 1
NCBC GULFPORT
GULFPORT, MISSISSIPPI
PAGE 2 OF 2**

Footnotes:

- 1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations and as one sample when determining the frequency of detection and average results.
- 2 - Values presented are sample-specific quantitation limits.
- 3 - The maximum detected concentration is used for screening purposes.
- 4 - A comparison of maximum concentrations was conducted between the site and background datasets. The maximum background concentration is shaded if the maximum site concentration exceeds the maximum background concentration. Sample 01GW2301 was used as the background dataset.
- 5 - Mississippi Department of Environmental Quality (MDEQ), Risk Evaluation Procedures for Voluntary Cleanup and Redevelopment of Brownfield Sites for Groundwater, February 2002. Noncarcinogenic values are divided by 10.
- 6 - Oak Ridge National Laboratory (ORNL) Regional Screening Level for Tapwater. The noncarcinogenic values (denoted with a "N" flag) are the screening level divided by 10 to correspond to a target hazard quotient of 0.1. Carcinogenic values represent an incremental cancer risk of 1.0E-06 (carcinogens denoted with a "C" flag) (ORNL, April 2009).
- 7 - 2006 Edition of the Drinking Water Standards and Health Advisories (USEPA, August 2006). SMCLs are presented for reference purposes only.
- 8 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
- 9 - Values are for endrin.
- 10 - Values are for hexavalent chromium.
- 11 - The MCL for this parameter is actually a treatment technique. The SDWA action level (at the tap) has been presented.

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Associated Samples:

Footnotes:

- Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations and as one sample when determining the frequency of detection and average results.
 - Values presented are sample-specific quantitation limits.
 - The maximum detected concentration is used for screening purposes.
 - No site-specific background sediment data were available for NCBC Gulfport.
 - Mississippi Department of Environmental Quality (MDEQ), Risk Evaluation Procedures for Voluntary Cleanup and Redevelopment of Brownfield Sites for Unrestricted and Restricted Land Use, February 2002. Noncarcinogenic values are divided by 10.
 - Oak Ridge National Laboratory (ORNL) Regional Screening Level for Residential Soil. The noncarcinogenic values (denoted with a "N" flag) are the screening level divided by 10 to correspond to a target hazard quotient of 0.1. Carcinogenic values represent an incremental cancer risk of 1.0E-06 (carcinogens denoted with a "C" flag) (ORNL, April, 2009).
 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level.
 - Values are for pyrene.
 - Values are for chlordanes.
 - Values are for alpha-BHC.
 - Values are for hexavalent chromium.
 - Ten percent of the noncarcinogenic value is less than the carcinogenic value, therefore the noncarcinogenic is presented.
- Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Definitions:

- C = Carcinogen
- COPC = Chemical Of Potential Concern
- J = Estimated value
- mg/kg = milligrams per kilogram
- ug/kg = micrograms per kilogram
- N = Noncarcinogen
- NA = Not Applicable/Not Available
- S = Concentration may exceed Csat
- sat = soil saturation concentration

Rationale Codes:

- For selection as a COPC:
ASL = Above Screening Level
- For elimination as a COPC:
BSL = Below COPC Screening Level
NUT = Essential nutrient
NTX = No toxicity criteria

Associated Samples:

Notes:

The exposure point concentrations (EPCs) were calculated according to USEPA's ProUCL guidance. See the RAGS PART D Table 3s in Appendix D for details concerning the EPCs.

NA - Not applicable. Not a COPC for this media.

1 - Maximum Detected Concentration

2 - Tetrachloroethene was selected as a COPC in direct push technology (DPT) groundwater samples only.

3 - Trichloroethene was selected as a COPC in both DPT and monitoring well samples for the vapor intrusion pathway. The maximum concentration of the two groundwater data sets was used as the EPC.

µg/L = micrograms per liter

mg/kg = milligrams per kilogram

Footnotes:

- 1 - USEPA, 2002: Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites. OSWER 9285.6-10.
- 2 - USEPA, 2002: Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites. OSWER 9355.4-24.
- 3 - USEPA, 1989: Risk Assessment Guidance for Superfund. Vol 1: Human Health Evaluation Manual, Part A. EPA/540/1-89/002.
- 4 - USEPA, 2004: Risk Assessment Guidance for Superfund (Part E, Supplemental Guidance for Dermal Risk Assessment) Final. EPA/540/R/99/005.
- 5 - Assumed 25 percent of total body surface area is exposed.
- 6 - Professional judgment. Assumes a one year construction project. Construction workers are assumed to be exposed to soil during the entire project. Exposure to groundwater, surface water, and sediment are assumed to occur for only 30 days a year.
- 7 - Assumes receptor is exposed to surface water and sediment 2 days per month.
- 8 - Assumes wading 2 to 3 days per week during summer months.
- 9 - Assumes a total 30 year exposure, 11 years for an adolescent (6 to 16 years old) and the remaining 19 years for an adult.
- 10 - USEPA Region 4: Supplemental Guidance to RAGS: Region 4 Bulletins, Human Health Risk Assessment Bulletins. May 2000. See text.
- 11 - Less than ten samples were collected; therefore, the maximum detected concentration was used as the exposure point concentration.
- 12 - USEPA, 1997: Exposure Factors Handbook. EPA/600/8-95/002FA.

- 6 Professional Judgment. Assumes one half the RME exposure.
- 7 - Assumes receptor is exposed to surface water and sediment one day per month.
- 8 Assumes a total 30 year exposure, 11 years for an adolescent (6 to 16 years old) and the remaining 19 years for an adult.
- 9 - USEPA Region 4: Supplemental Guidance to RAGS: Region 4 Bulletins, Human Health Risk Assessment Bulletins. May 2000.
- 10 - Less than ten samples were collected therefore the maximum detected concentration was used as the exposure point concentration.
- 11 - USEPA, 1997: Exposure Factors Handbook. EPA/600/8-95/002FA.

7.0 ECOLOGICAL RISK ASSESSMENT

This ecological risk assessment was conducted to evaluate potential site-related risks to ecological receptors at Site 1, the Disaster Recovery Disposal Area. The ecological risk assessment consisted of Steps 1 through 3A of USEPA's 8-step ecological risk assessment process, and was conducted in accordance with USEPA and Navy guidance (USEPA, 1997a; 2000b; 2001b; DON, 1999). Steps 1 through 3A consist of the following:

- Step 1 Screening-Level Problem Formulation and Ecological Effects Evaluation
- Step 2 Screening-Level Exposure Estimate and Risk Calculation
- Step 3A Refinement of Preliminary Chemicals of Potential Concern

Section 7.1.1 describes the environmental setting at Site 1. The fate and transport characteristics of chemicals detected in soil, sediment, and surface water are provided in Section 7.1.2. The ecotoxicity of site contaminants and potential ecological receptors are described in Section 7.1.3. Section 7.1.4 describes complete exposure pathways, and Section 7.1.5 provides assessment and measurement endpoints. Sections 7.2, 7.3, and 7.4 describe the ecological effects evaluation, exposure estimates, and risk calculation, respectively. Section 7.5 describes the refinement of preliminary COPCs. Uncertainties inherent in the ecological risk assessment are discussed in Section 7.6. The summary and conclusions of the ecological risk assessment are provided in Section 7.7. Additional information regarding the food chain modeling can be found in Appendix F.

7.1 SCREENING-LEVEL PROBLEM FORMULATION

7.1.1 Environmental Setting

Site 1 is a former landfill facility encompassing approximately 9 acres, although the areal extent of the waste disposal is likely much smaller. The site is located north of 7th Street and east of Colby Avenue (Figure 2-2). The site is bordered on the north by facilities of the Pine Bayou Golf Course. The site topography is relatively flat, with elevations of approximately 20 to 24 feet above mean sea level. This area has most recently been used as a mock disaster recovery training village and as a training facility. The landfill was operated from 1942 until 1948, during which time it received nearly all of the solid and chemical waste generated at NCBC Gulfport. In addition to the solid waste, waste fuel, oil, solvents, paint, and paint thinners, reportedly in 55-gallon drums, were transported to the site and buried in trenches (Envirodyne, 1985).

In 1984, during water line repairs in the southwestern portion of Site 1, four or five rusted 55-gallon drums were excavated. The drums were highly deteriorated, and the drum contents were described as tar-like in consistency with a strong odor similar to burnt plastic. The drums were transported to the concrete foundation of former Building 271 (later designated Site 9) for storage pending analytical results of the drum contents. The sample of drum contents was analyzed for hazardous waste characterization for metals and volatiles and for flammability, reactivity, and corrosiveness. The material sampled from the drums contained xylene, toluene, 1,2-dichloroethane, and low levels of arsenic and lead.

Materials at Site 1 were disposed in trench and fill operations, often accompanied by incineration prior to covering the trenches with soil. As a trench and fill operation, wastes were often placed at or near the groundwater with no lining. The waste disposal area at Site 1 was covered with soil when disposal activities ceased in 1948. Additional fill has been added over the years as parking lots and roads have been constructed over the surface. The uppermost 2 feet in most areas is fill material used in the construction of the golf course over the landfill. Buildings at Site 1 are intermittently occupied, and it is unknown if any of the buildings were constructed on top of the disposal trenches.

Shallow groundwater flow at the site is to the northwest and northeast. Deep groundwater flow in and around Site 1 is to the northwest. There are no reports of the disposal of ordnance, radiological material, or biological/chemical warfare agents at Site 1.

Most precipitation presumably infiltrates into the sandy soils at the site with any surface water runoff conveyed to ditches along the eastern and western boundaries of the site. The ditch on the east boundary of the site typically contains water; and drains to the 28th Street area. The ditch on the west boundary of the site is very shallow, contains less water than the eastern ditch, is concrete-lined with numerous cracks in the concrete, and drains to Canal No. 1 on the northern side of 8th Street. Both ditches drain northward. Surface water in both ditches is typically stagnant or slow flowing. The drainage ditch on the western side of the site receives the majority of surface water runoff from the disposal area. Small fish, tadpoles, and a limited amount of aquatic vegetation have been observed in the western ditch. Being larger and normally containing water, the eastern ditch contains more aquatic life and plants. The ditches at Site 1 are usually wet because of their low-lying nature and the shallow regional water table. It does not appear that groundwater is discharging into the ditches. The drainage ditches at Site 1 are part of the network of interconnected ditches and canals that convey storm water on the base. The ditches are generally straight and uniform in width, lacking the morphological properties of natural streams. Some aquatic plants grow in stable sand and gravel banks near and below water levels. Wading birds, fish, and benthic organisms have been observed in the ditches.

Ground cover at the site is predominantly maintained grass, with a mixture of planted pines, hardwoods, roads, and several small buildings. A portion of the golf course occupies the northern one-third of Site 1. Large trees are scattered over the southern portion of the site. Some wildlife species (e.g., small birds, squirrels) undoubtedly forage at Site 1, especially in the southern portion of the site, but wildlife use of the northern portion of the site is temporary and minimal due to the lack of suitable cover on the golf course. Snakes, turtles, frogs, and Canada geese have been observed at or near the site. Various bird species may forage at the southern portion of the site and to a limited extent on the golf course fairway and rough areas, consuming invertebrates in the soil and grass as well as seeds blown in from nearby wooded areas. The grass height at the golf course and southern portions of the site is too low to provide cover for small mammals such as shrews and mice. With the exception of invertebrates and birds, probably few receptors forage at the site during daylight hours. The site is undoubtedly traversed by some wildlife species, especially at night. The more wooded areas in the southern portion of the site provide favorable conditions for a more diverse assemblage of plants and animals. Wildlife species expected to occur in these areas, especially at night, include mammals such as the Eastern cottontail (*Sylvilagus floridanus*), opossum (*Didelphis virginiana*), and raccoon (*Procyon lotor*).

7.1.2 Contaminant Fate and Transport

A portion of the area encompassing Site 1 was used as a landfill from 1942 until 1948 during which time it received nearly all of the solid and chemical waste generated at NCBC Gulfport. In addition to the solid waste, waste fuel, oil, solvents, paint, and paint thinners were transported to the site and buried in trenches (Envirodyne, 1985).

Metals, VOCs, SVOCs, pesticides, herbicides, and PCBs have been detected in surface soil samples collected at the site. Metals, VOCs, SVOCs, pesticides, and herbicides have been detected in nearby surface water and sediment samples. A discussion of the fate and transport of these contaminants was presented in Section 5. The discussion below is limited to a brief review of the fate and transport of contaminants at Site 1 as related to migration pathways and ecological exposure.

The former landfill and the original contaminant sources are covered by fill dirt and a surface layer of maintained grass. As mentioned earlier, the topography is relatively flat. Because of these conditions, stormwater erosion, wind erosion, and overland transport of site-related contaminants in surface soil are not considered primary contaminant transport mechanisms at Site 1. However, if surface soil is disturbed through activities such as excavation, soils could serve as a source for airborne transport of contaminants; soil contaminants could then be transported to downwind locations. Excavation of soil could also result in the volatilization of some contaminants. If disturbed, soils might also be transported by stormwater erosion to surface water and sediment.

Infiltrating precipitation has resulted in the contamination of groundwater at the site. Although no groundwater seepage points have been observed in the ditches along the eastern and western edges of the site, the primary contaminant migration pathway (as related to ecological receptors) at Site 1 is probably infiltration of soil contaminants into groundwater and subsequent potential seepage into the ditches.

7.1.2.1 VOCs

VOCs are poorly adsorbed to soil and sediment particles. Also, because they are very volatile, they typically are detected in surface water, surface soil, and sediment only at low concentrations. VOCs in soil will dissolve in rain water to varying degrees and can be transported overland with runoff or into groundwater. Photolysis and hydrolysis are not significant mechanisms for VOC degradation. Aerobic biodegradation in soil and groundwater is significant, however, and anaerobic degradation can also occur in these media.

7.1.2.2 SVOCs

Most SVOCs detected in Site 1 surface soil and sediment were PAH and phthalate compounds. PAHs are ubiquitous in the modern environment and are common constituents of coal tar, soot, vehicle exhaust, cigarette smoke, certain petroleum products, road tar, mineral oils, creosote, and many cooked foods. PAHs can also be released to the environment through natural sources such as forest fires. The fate and transport characteristics of PAHs are dependent on their molecular weights. Low molecular weight PAHs are more soluble and volatile, and therefore more mobile. They can volatilize and photolyze from soil and surface water, and they can also be biodegraded. High molecular weight PAHs tend to be immobile and insoluble, binding strongly to organic matter (reducing the potential for leaching to groundwater), and they are resistant to volatilization, photolysis, and biodegradation (Eisler, 2000). Upper trophic level organisms are exposed to PAHs primarily through their diet, but most wildlife can metabolize and excrete PAHs. Food-chain transfer and biomagnification of PAHs are expected to be minimal. PAHs can be absorbed by plants but are expected to be translocated, metabolized, and potentially photodegraded. Accumulation within plants is likely to occur only in heavily polluted locations where uptake exceeds metabolism and degradation (Edwards, 1983).

Three phthalates were detected at Site 1. Plastic wastes are the major source of phthalates in the environment, and phthalates are relatively persistent in the environment. Some microorganisms have been shown to excrete products that increase the solubility of phthalates and enhance their biodegradation (Gibbons and Alexander, 1989). Diethyl phthalate tends to undergo aerobic biodegradation in soil and surface water, while anaerobic biodegradation would be very slow or not occur at all. Diethyl phthalate has accumulated and persisted in the sediments of Chesapeake Bay for over a

century (Spectrum, 2003). Phthalates are not expected to significantly volatilize. Phthalates have been found in groundwater at high concentrations at sites with highly permeable soils, which demonstrates that at high concentrations, they can leach into groundwater. Biomagnification of phthalates does not occur.

7.1.2.3 Pesticides

Organochlorine pesticides were detected in surface soil and sediment at Site 1. Organochlorine pesticides are highly persistent in the environment, and tend to tightly sorb to organic matter and be immobile in most soils. Degradation of chlorinated pesticides in soil would eventually occur through volatilization, photolysis, and aerobic and anaerobic degradation. Due to the lipophilicity of organochlorine pesticides, they can bioaccumulate in animals. These compounds generally bioconcentrate in lower trophic level organisms and can be transferred and magnified in higher trophic level organisms.

7.1.2.4 Herbicides

The chlorophenoxy herbicide 2,4,5-T was detected in surface soil and surface water while dinoseb was detected in surface soil. 2,4,5-T was once widely used in agriculture, along highways, and on lawns, but its use in the United States has been cancelled since 1985. Dioxins and furans were byproducts formed during the production of 2,4,5-T and early batches were relatively highly contaminated with TCDD. Eventually, USEPA regulated the TCDD content in 2,4,5-T at 0.1 ppm or less (Amdur et al, 1991). The mobility of 2,4,5-T varies from highly mobile in sandy soil to slightly mobile in mucky sediment (due to adsorption to humic acids and other organic matter). Photochemical decomposition, volatilization and biodegradation appear to be the dominant removal mechanisms in water. Bioconcentration and biomagnification are not significant (HSDB, 2009). Release of dinoseb to soil is expected to result in biodegradation, and dinoseb will only weakly adsorb to soils and should, therefore, leach to groundwater. However, it may bind more strongly to clay soils, especially at acidic pH. Photolytic degradation of dinoseb from soil surface may occur. Dinoseb may photodegrade in surface water with a half-life of 14 to 18 days. Hydrolysis in water is not significant. It is unlikely to undergo significant biodegradation in most natural waters. Volatilization from water is expected to be slow and bioconcentration is expected to be insignificant (HSDB, 2009).

7.1.2.5 PCBs

The PCB Aroclor-1260 was detected in one surface soil sample at Site 1. PCBs include a variety of mixtures of individual biphenyl isomers, each consisting of two joined benzene rings and up to 10 chlorine atoms. PCBs adsorb strongly to soil particles with adsorption generally increasing with the degree of chlorination. PCBs released into water adsorb to sediments and other organic matter. Factors that

determine the biodegradability of PCBs include the amount of chlorination, concentration, microbial population type, available nutrients, and the temperature (ATSDR, 1989). PCBs can significantly bioconcentrate in animals.

7.1.2.6 Inorganics

Metals were detected in surface soil, surface water, and sediment at Site 1. Many metals occur naturally in soil, sediment, and surface water due primarily to chemical weathering of rocks. They are toxic to aquatic and terrestrial receptors above certain concentrations, with some metals being more toxic at lower concentrations than others. In addition, different chemical forms of metals are more toxic than others. For example, hexavalent chromium is typically more toxic than trivalent chromium, and methyl mercury is more toxic than inorganic mercury. Some metals have the potential to accumulate in biota.

7.1.3 Ecotoxicity and Potential Receptors

VOCs readily volatilize, are poorly adsorbed to soil and sediment particles, and are typically detected in surface soil and sediment only at low concentrations. VOCs do not generally bioaccumulate in ecological receptors, and their toxicity to ecological receptors is relatively low.

Few generalizations can be made about the ecotoxicity of PAHs because of the extreme variability in toxicity and physiochemical properties of PAHs. Adverse impacts to plants from PAHs, however, are rare (Eisler, 2000). In most animal species, PAHs are metabolized by a mixed-function oxidase enzyme system into intermediates that may be toxic, mutagenic, or carcinogenic to the host. Some invertebrate species cannot efficiently metabolize PAHs (Eisler, 2000), and PAHs can be chronically toxic to invertebrates, but overall, very little is known about the toxicological mechanisms of PAHs in invertebrates (Erstfield and Snow-Ashbrook, 1999). PAHs can bind to cellular macromolecules and thereby disrupt their function in higher level organisms such as mammals and birds. Biological macromolecules include polymers of carbohydrates (e.g., starch), amino acids (proteins), and nucleotides (e.g., DNA). The cellular functions of these polymers include structure, energy storage, energy transfer, material transport, and the storage and transmittal of genetic information. PAHs show little tendency to biomagnify in the food web (Eisler, 2000). Microbial metabolism is the major process for degradation of PAHs in soil (ATSDR, 1997). PAHs show little tendency to biomagnify in the food web. USEPA Region 4 considers the potential toxicity of PAHs via the terrestrial food web to be generally negligible unless PAHs are present at extremely high concentrations (i.e., percent levels: 10,000 mg/kg) in soil.

Chronic oral exposure to phthalates can result in liver toxicity in mammals. Ingested phthalates metabolize to monoesters in the gut and are subsequently absorbed. Following absorption, phthalates distribute primarily to the liver and kidneys and may, in some species, concentrate in the testes (Rhodes

et al., 1986). Liver carcinogenesis has been observed (ATSDR, 1997). Many receptors are able to metabolize and excrete phthalate esters, so their ability to bioaccumulate varies among species.

Organochlorine pesticides are reproductive and nervous system toxins. Although these compounds were used as insecticides, they are toxic to other animals as well. The target organ for acute exposures is the nervous system, while chronic exposures can affect the liver and endocrine systems of higher animals. Organochlorine pesticides are lipophilic and can be stored in the fat tissue of organisms such as birds and mammals. In birds of prey they can cause reproductive failure through eggshell thinning and disruption of egg-laying and nesting cycles (Amdur et al., 1991). These pesticides were developed to control insects on crops, and as a result, they are practically non-toxic to plants.

The herbicide 2,4,5-T exerts its herbicidal action by acting as a growth hormone in plants (Amdur, 1991). Laboratory studies indicate that 2,4,5-T is only slightly toxic to most animals, and is not carcinogenic or teratogenic. Laboratory no-adverse-effect levels (NOAELs) for aquatic species are typically greater than 1,000 µg/L, classifying 2,4,5-T as practically non-toxic. 2,4,5-T is practically non-toxic to mallards, and is slightly toxic to pheasants (HSDB, 2009).

PCBs are highly lipophilic, and can bioaccumulate in animals. PCBs can accumulate in offspring through placental transfer in mammals and accumulation in bird eggs, and can accumulate in upper trophic level animals such as piscivorous birds and mammals that feed on contaminated prey items (Eisler, 2000). In animals, the primary effect associated with PCB exposure is the induction of liver enzyme systems. These enzymes are associated with detoxification mechanisms and with the metabolism of hormones. Adverse reproductive effects observed with PCB exposure are associated with induction of the enzyme systems. The toxicity of PCBs to mammals and birds varies, depending on the particular PCB and the animal species. PCBs are not water soluble and accumulate to a much greater degree in animals than in plants. Nevertheless, plant-related effects of PCB exposure can include slower growth, reduced chlorophyll content, and diminished photosynthesis (USEPA, 1999).

It is difficult to make generalizations about the toxic actions of metals because of diverse affinities for organic molecules in biologic structures, a wide array of biological effects, and a multiplicity of target organs and systems (Amdur et al., 1991). At the molecular level, metals can manifest toxicity in many ways, including selectively accumulating in target organs (such as the kidneys), substituting for “essential” metals, and mimicking essential substrates (Clarkson, 1983). The reactions of metals at the molecular level typically affect enzyme systems, leading to disruption of cellular transport, cellular respiration, cell division, and other physiological processes. Metal toxicity to aquatic organisms is manifested through a broad spectrum of effects that may range from a reduction in growth rate to death.

7.1.4 Complete Exposure Pathways

As mentioned earlier, the former landfill is covered by fill dirt, landscaping, roadways, and houses. Therefore, exposure to landfill-related contaminants by terrestrial ecological receptors is probably minimal. However, the possibility that soil has been disturbed during excavation, such as laying pipes or other activities, cannot be ruled out. As a conservative measure, therefore, it will be assumed that the soil cover is not of uniform thickness, and the soil exposure pathway will be assumed to be complete. To the extent that this is true, soil invertebrates could be exposed to soil contaminants at Site 1 through ingestion and dermal contact, and the root zone of some plants (especially trees) might extend into contaminated soil.

The ground cover at Site 1 appears to be managed and regularly maintained. The grass height at both the golf course on the northern third of the site and the areas south of it appear similar to that of a recently mowed lawn. In the absence of other cover, the grass height is too low to provide cover for small mammals such as shrews and mice. Although various bird species may forage in the more wooded sections of the site, birds would not be significantly exposed to site-related contaminants, since site contaminants are buried underneath fill material. The waste disposal area at Site 1 was covered with soil when disposal activities ceased in 1948. Additional fill has been added over the years as parking lots and roads have been constructed over the surface. Even if small areas of site-related surface soil contamination are present, such areas would comprise only a miniscule amount of foraging habitat for wide-ranging receptors such as birds. With this in mind, the exposure pathway for terrestrial receptors such as birds, mammals, and reptiles is incomplete or negligible and insignificant.

Aquatic organisms such as fish and benthic organisms (i.e., invertebrate organisms that live on or in sediment) could be exposed to sediment and surface water contaminants through ingestion and direct contact. Higher trophic level animals such as birds and mammals that forage in the ditches at Site 1 can be exposed to site-related contamination through ingestion of contaminated food items and water. These animals may also incidentally ingest contaminants in sediment while preening feathers or feeding on items to which sediment has adhered. Absorption of contaminants from the gastrointestinal tract is the primary pathway of intake for upper trophic level receptors.

In summary, complete exposure pathways and routes of entry into biota at Site 1 consist of:

- Direct contact with soil, sediment, and surface water
- Ingestion of soil, sediment, and surface water
- Ingestion of contaminated food items by upper trophic level animals foraging in the ditches along the eastern and western edges of the site.

7.1.5 Preliminary Assessment and Measurement Endpoints

An assessment endpoint is “an explicit expression of the environmental value that is to be protected,” while a measurement endpoint is “a measurable ecological characteristic that is related to the valued characteristic chosen as the assessment endpoint” (USEPA, 1997). Measurement endpoints represent the assessment endpoints chosen for a site, and are measures of biological effects (USEPA, 1997a).

USEPA Region 4 has specified that assessment endpoints for the screening-level assessment should be broad and generic. For the Site 1 screening level assessment, the preliminary assessment endpoint is the protection of terrestrial, benthic, and aquatic biota from adverse effects of chemicals on their growth, survival, and reproduction. The preliminary measurement endpoints are chemical concentrations in surface soil, sediment, and surface water that are associated with no adverse effects on growth, survival, and reproduction of terrestrial and benthic organisms. The measurement endpoints are represented by USEPA Region 4 ESVs for surface soil, surface water, and sediment.

The soil, surface water, and sediment ESVs are based on conservative endpoints and sensitive ecological effects data, and thus, the screening values represent chemical concentrations associated with a low probability of unacceptable risks to ecological receptors. For this reason, USEPA Region 4 considers their screening values to be protective of invertebrates and plants as well as upper level receptors such as birds and mammals. In the screening level ecological risk assessment, therefore, a distinction is not made between measurement endpoints associated with direct toxicity to invertebrates and plants versus measurement endpoints associated with food chain effects.

7.2 SCREENING-LEVEL ECOLOGICAL EFFECTS EVALUATION

Soil screening values used in the screening level ecological risk assessment were USEPA Ecological Soil Screening Levels (Eco-SSLs) and ESVs established by USEPA Region 4 (USEPA, 2001). The lowest Eco-SSL among plant, invertebrate, mammal, and avian values was used as the screening value. Eco-SSLs were preferentially used as soil screening values, but Eco-SSLs are currently available for only a few chemicals. USEPA Region 4 ESVs (USEPA, 2001b) were used as soil screening values for chemicals that do not have an Eco-SSL. The term “soil ESV” is generally used for brevity in this Section to refer to either the Eco-SSL or the Region 4 soil ESV.

ESVs for surface water and sediment used in the screening level ecological risk assessment were those established by USEPA Region 4 (USEPA, 2001b).

If the maximum detected concentration of a chemical in surface soil, sediment, or surface water was equal to or less than the ESV, the chemical was eliminated from further consideration for that medium. If

the maximum concentration exceeded the ESV, or if a screening value was not available, the chemical was then considered to be an ecological COPC and was retained for further evaluation.

7.3 SCREENING-LEVEL EXPOSURE ESTIMATE

Exposure point chemical concentrations for surface soil were obtained from 21 samples collected in August and September 2008 (Figure 2-3). Surface soil samples were collected from a depth of 0 to 1 foot, and the term “surface soil” is used in this risk assessment to refer to samples collected from this depth, since USEPA Region 4 considers 0 to 1 foot depth to be representative of surface soil. The surface soil sample locations were based on previous investigations and are believed to represent the area encompassed by the former landfill.

Exposure point chemical concentrations for sediment and surface water were obtained from five sediment samples and five surface water samples collected in March 2008 (Figure 2-7). Three surface water/sediment samples were collected from the ditch bordering the western side of Site 1, and two surface water/sediment samples were collected from the ditch bordering the eastern side of the site.

7.4 SCREENING-LEVEL RISK CALCULATION

The screening level risk calculation step compared maximum concentrations of chemicals in surface soil, sediment, and surface water to ESVs. The ratio of the maximum concentration to the ESV is called the screening HQ. Analytes with maximum concentrations less than or equal to ESVs ($HQ \leq 1$) were dropped from further consideration, while those that exceeded ESVs ($HQ > 1$), or did not have ESVs, were retained as ecological COPCs. An HQ value greater than 1 indicates that ecological receptors are potentially at risk, and further evaluation or additional data may be necessary to confirm with greater certainty whether ecological receptors are actually at risk, especially since most toxicity benchmarks are developed using conservative exposure assumptions. Chemicals that were retained as COPCs were evaluated in Step 3A so that risk managers can determine if further investigation is warranted.

Calcium, magnesium, potassium, and sodium were not considered to be COPCs because they are essential nutrients that can be tolerated by living systems even at relatively high concentrations. There have been no activities at NCBC Gulfport that have resulted in known releases of high levels of these four chemicals at Site 1.

In surface soil, four pesticides and nine inorganics were retained as COPCs because their maximum concentrations exceeded ESVs, while ESVs were not available for two VOCs, one SVOC, seven pesticides, and two herbicides (Table 7-1).

In surface water, three inorganics were retained as COPCs because their maximum concentrations exceeded ESVs, while ESVs were not available for three VOCs, one SVOC, one herbicide, and two inorganics (Table 7-2).

In sediment, six SVOCs, two pesticides, and three inorganics were retained as COPCs because their maximum concentrations exceeded ESVs, while ESVs were not available for three VOCs, four SVOCs, four pesticides, and six inorganics (Table 7-3).

The full surface soil, sediment, and surface water datasets are presented in Appendix D.

7.5 REFINEMENT OF PRELIMINARY CHEMICALS OF POTENTIAL CONCERN

At this point, the first two steps of the ecological risk assessment have been completed. The ecological risk assessment process includes a series of scientific/management decision points (SMDPs) (USEPA, 1997a). The first SMDP occurs at the end of Step 2 (Screening Level Exposure Estimate and Risk Calculation), and requires the risk managers to evaluate and approve or redirect the work up to that point and determine whether the risk assessment will continue into Step 3. However, USEPA Region 4 recognizes that most ecological risk assessments will proceed into Step 3, and facilities are encouraged to submit the results of Steps 1-3 as a single deliverable document (USEPA, 2000b). With this in mind, and since the screening level ecological risk assessment indicates a potential for adverse effects, a more thorough assessment is warranted. Therefore, the risk assessment process for Site 1 will proceed into Step 3 (Baseline Risk Assessment Problem Formulation).

7.5.1 General Approach

The baseline ecological risk assessment begins with a more balanced evaluation of the conservativeness inherent in the first two steps of the risk assessment process (USEPA, 1997a; DON, 1999). The initial phase of Step 3 is typically known as Step 3A, and consists of a refinement of the conservative exposure assumptions in order to more realistically estimate potential risks to plants, invertebrates, and wildlife receptors. Examples of factors typically considered during Step 3A include toxicological evaluation of COPCs, spatial distribution of contaminants, frequency of detection, background concentrations, and habitat quality. Furthermore, the preliminary assessment and measurement endpoints are refined, the site conceptual model is developed, and initial food chain modeling is conducted (at sites where applicable) to evaluate risks to upper level receptors (USEPA, 2000b). The objective of the Step 3 refinement is to better define those chemicals that contribute to potentially unacceptable levels of ecological risk, and to identify and eliminate from further consideration those chemicals that were initially selected as COPCs because of the use of very conservative assumptions.

7.5.2 Assessment and Measurement Endpoints

Based on the habitats present and on the migration pathways and routes of exposure of chemicals at Site 1, the site-specific assessment endpoints are the protection of the following groups of receptors from adverse effects of site-related contaminants on growth, survival, and reproduction:

- Soil invertebrates
- Terrestrial plants
- Benthic invertebrates
- Aquatic organisms
- Piscivorous birds
- Piscivorous mammals

The assessment endpoints listed above were selected for evaluation in Step 3A of the baseline ecological risk assessment for the reasons described below.

7.5.2.1 Soil Invertebrates

Earthworms, insect larvae, and other soil invertebrates at Site 1 aid in the formation of soil and the redistribution and decomposition of organic matter in soil. They can also accumulate bioaccumulative contaminants that can then be transferred to higher trophic-level organisms that consume soil invertebrates.

7.5.2.2 Terrestrial Vegetation

Terrestrial vegetation at Site 1 consists largely of mowed grass in the northern one-third of the site, with more trees, shrubs, vines, and herbs present in the southern portion of the site. These plants serve as a food source and provide shade and cover for various organisms, and they help to prevent soil erosion, among other important functions. They also can accumulate certain contaminants that can then be transferred to the higher trophic-level organisms that consume plants. The existing soil cover over the former landfill probably minimizes the exposure pathway to terrestrial vegetation, but as a conservative measure, potential risk to terrestrial vegetation was evaluated.

7.5.2.3 Benthic Invertebrates

A variety of benthic invertebrates such as crayfish and immature forms of numerous insect species may occur in the ditches bordering Site 1. Benthic invertebrates may be exposed to site-related contaminants through groundwater discharge into the ditches and to a minor extent (as previously discussed) from

storm water runoff. Benthic invertebrates can accumulate contaminants that can then be transferred to higher trophic level organisms when consumed. These invertebrates serve as prey items for reptiles and amphibians, for mammal species such as the opossum, raccoon, and mink, and for numerous bird species.

7.5.2.4 Aquatic Organisms

Fish and other aquatic organisms such as daphnids, midges, and mosquito larvae are present in the ditches bordering Site 1. They are directly exposed to contaminants in surface water. Aquatic organisms serve as a food source for higher trophic level organisms such as birds and mammals. Like benthic invertebrates, aquatic biota can accumulate contaminants that can then be transferred to higher trophic level organisms when consumed.

7.5.2.5 Piscivorous Birds and Mammals

The term “piscivorous” is used here in a broad sense to describe birds and mammals that prey upon not only fish, but on a variety of aquatic and sediment dwelling organisms (e.g., crayfish, frogs). Piscivorous birds and mammals can be exposed to and accumulate site-related contaminants that have accumulated in prey items obtained from the site. This would be especially applicable for contaminants such as organochlorine pesticides, and certain metals. Piscivorous birds that forage in water bodies near Site 1 include wading birds such as herons and egrets. Probably few if any piscivorous mammal species forage in the ditches adjacent to Site 1, due to the open habitat and lack of trees and shrubs along the shorelines, but the occasional presence of mammals such as the river otter and mink cannot be ruled out. Raccoons undoubtedly forage in the ditches. The raccoon is often thought of as piscivorous, and it does consume aquatic organisms, but the majority of its diet typically consists of non-aquatic animal and plant tissues (USEPA, 1993a).

7.5.2.6 Other Potential Endpoints

As indicated in USEPA guidance (USEPA, 1997a), it is not practical to directly evaluate risks to all of the individual components of the ecosystem. Instead, assessment endpoints focus the risk assessment on particular components of the ecosystem that will tend to yield the highest risks; this should provide protection for endpoints that have lower risks.

As mentioned earlier, the former landfill is covered by fill dirt within an intensively managed landscape. With this in mind, the surface soil exposure pathway for terrestrial receptors such as birds, mammals, and reptiles is incomplete or negligible and insignificant. In addition, threshold oral toxicity values for reptiles and amphibians are not available for most chemicals. With the above factors in mind, amphibians,

reptiles, herbivores, and omnivores were not selected as assessment endpoints. Instead, potential risk from bioaccumulation and biomagnification of contaminants was assessed for piscivorous birds and mammals.

7.5.2.7 Measurement Endpoints

Measurement endpoints for soil invertebrates, benthic invertebrates, and aquatic organisms in Step 3A of the baseline ecological risk assessment are similar to those in the screening level assessment: chemical concentrations in surface soil, sediment, and surface water that are associated with adverse effects on growth, survival, and reproduction of soil invertebrates and benthic and aquatic organisms. The measurement endpoints are represented by ESVs for surface soil, sediment, and surface water. Other guidelines were also used in some instances.

Adverse impacts on survival, growth, and reproduction of piscivorous birds and mammals were evaluated by comparing estimated ingested doses of contaminants in surface water, sediment, and food items to threshold oral toxicity values.

7.5.3 Conceptual Exposure Model

The site conceptual exposure model is designed to diagram the potentially exposed receptor populations and applicable exposure pathways based on the physical nature of the site and the potential contaminant source areas. The contaminant transport pathways for Site 1 are shown schematically on Figure 7-1. These pathways describe the movement from sources of contamination to potential ecological receptors; the linkage of these items is the conceptual site model.

Overland runoff and erosion appear to be negligible at the relatively flat and vegetation-covered site, and are not included on Figure 7-1. The aquatic and benthic organisms referred to on Figure 7-1 are those in the ditches bordering the east and west sides of the site. Combustion was undoubtedly a major contaminant release mechanism during the period of active landfill and burning operations. However, combustion is not a current contaminant release mechanism at Site 1 since burning activities have ceased and the landfill is covered with soil. The soil cover also precludes the volatilization pathway.

7.5.5 Step 3A Risk Characterization and Discussion

Several chemicals that were detected in surface soil, sediment, and surface water were initially retained as ecological COPCs because their chemical concentrations exceeded ESVs or because ESVs were not available. The remainder of this section discusses soil COPCs as related to terrestrial invertebrates and

plants (Section 7.5.4.1), surface water and sediment COPCs as related to aquatic and benthic receptors (Section 7.5.4.2), and COPCs that pose risk to piscivorous wildlife via the food chain (Section 7.5.4.3).

7.5.4.1 Potential Risk to Terrestrial Invertebrates and Plants

7.5.4.1.1 Volatile Organic Compounds

2-butanone (methyl ethyl ketone) and 4-methyl-2-pentanone (methyl isobutyl ketone) were retained as COPCs in surface soil due to an absence of ESVs (Table 7-1). 2-butanone was detected in only two of 21 samples. Both positive detections were “J flagged”. This signifies that the analyte was positively identified but its concentration could not be precisely quantified since it was less than the contract-required quantitation limit but greater than the instrument detection limit. The majority of the detection limits were higher than the reported detected concentrations so there is uncertainty associated with these results. 2-butanone is a common laboratory contaminant. The concentrations of 2-butanone in surface soil at Site 1 probably do not pose risks to soil invertebrates and plants.

4-methyl-2-pentanone was detected in four of 21 samples. All positive detections were “J flagged”. The majority of the detection limits were higher than the reported detected concentrations so there is uncertainty associated with these results. 4-methyl-2-pentanone is used as a solvent and an extracting agent and occurs naturally in oranges and grapes. It may volatilize from dry soil surfaces based upon its vapor pressure, and biodegradation is an important environmental fate process (HSDB, 2009). Although the lack of toxicity data precludes a thorough evaluation of risks, detected concentrations of 4-methyl-2-pentanone at Site 1 are not anticipated to be associated with significant potential risk to soil invertebrates and plants.

7.5.4.1.2 Semivolatile Organic Compounds

Caprolactam is used in the manufacture of synthetic fibers and as a solvent for polymers, especially for nylon materials, plastics, paints, coatings, and floor polishes (HSDB, 2009). ESVs and surface soil toxicity data were not available, and a literature review compiled by the United Nations Environment Programme (UNEP, 2001) stated that no caprolactam toxicity data are available on terrestrial organisms. In summary, the lack of toxicity data precludes an evaluation of potential impacts to surface soil organisms. Caprolactam was detected in only three surface soil samples but was also detected in surface water samples. Caprolactam is expected to have high mobility due to its Koc of 57 (HSDB, 2009). This is consistent with the presence of caprolactam in surface water indicating potential migration into this media from soil.

7.5.4.1.3 Pesticides

Concentrations of dieldrin exceeded the ESV in three samples (Table 7-4). The maximum concentration (460 µg/kg) was much higher than the concentrations in the other samples that exceeded the ESV (15 µg/kg and 9.5 µg/kg). The ESV is the Eco-SSL for risk to mammals based on potential adverse impacts to the shrew from ingestion of earthworms rather than risks to plants or soil invertebrates. Data were insufficient to derive an Eco-SSL for plants and soil invertebrates.

The concentration of gamma-BHC (also known as lindane) exceeded the ESV in one sample, and the detection limits in non-detect samples also exceeded the ESV (Table 7-4). The Region 4 ESV is a “target” value established by the Dutch to represent the concentration required for the full functionality of human, animal, and plant life. Dutch target values are based on standards for drinking water and surface waters (MHSPE, 1994). The applicability of the 0.05 µg/kg ESV is unclear, so the potential risk posed by lindane at Site 1, is uncertain. However, since lindane was detected at only one location and its detected concentration was relatively low (0.23 µg/kg), potential impacts appear localized and minimal.

Aldrin and endrin aldehyde each exceeded their respective ESV in one sample (Table 7-4). Aldrin had a maximum HQ of 2.5 while endrin aldehyde had a maximum HQ of 2.0. In the absence of an ESV for endrin aldehyde, the ESV for endrin was used so there is some uncertainty in conclusions regarding potential risk from endrin aldehyde. The average concentrations of aldrin and endrin aldehyde were less than the respective ESVs. Both detections were “J flagged”. Potential risks from aldrin and endrin aldehyde are considered low and isolated to the single locations where they were detected.

ESVs were not available for alpha- and gamma-chlordane, endosulfan II, endosulfan sulfate, heptachlor, heptachlor epoxide, or methoxychlor. The average concentrations of these seven compounds were less than 1 µg/kg except for methoxychlor (Table 7-4). A background dataset has not been generated for NCBC Gulfport, so a comparison of concentrations at Site 1 to background values cannot be performed.

In summary, the pesticides detected at Site 1 are organochlorine insecticides that are no longer used but are known to be extremely persistent in soil. Concentrations in some samples might pose risks to soil invertebrates, after all, these insecticides were manufactured to control invertebrates. Potential risks (if any) might be due to historical use of these insecticides rather than landfill operations, but a background dataset has not been generated for NCBC Gulfport.

The USEPA Region 4 ESV for “total organochlorinated pesticides” is 100 µg/kg. Concentrations of total organochlorinated pesticides in only two Site 1 surface soil samples are above this value. Sample 01SS017 collected near a roadway had a methoxychlor concentration of 140 µg/kg, while sample 01SS025 collected near a house had a dieldrin concentration of 460 µg/kg. All other concentrations (both

individual and total) were much lower. Dieldrin was historically used for termite control through direct injection into soils as well as by treatment of timber and building materials and methoxychlor was widely sprayed for mosquito control. It is unclear whether the presence of these pesticides is associated with historic application or landfill operations.

7.5.4.1.4 Herbicides

2,4,5-T was detected in three of 21 samples and dinoseb was detected in one of six surface soil samples. 2,4,5-T is a plant hormone used as a herbicide and plant growth regulator. 2,4,5-T was historically applied to control plant growth on land and in water and is a component of Herbicide Orange which the U.S. Air Force stored in drums at NCBC Gulfport (Site 8) between 1968 and 1977. Cancellation of all registered uses of 2,4,5-T was effective January 2, 1985.

Dinoseb is a phenolic herbicide formerly used largely for the selective control of grass and broadleaf weeds. The use of dinoseb in the United States was cancelled by the USEPA in 1986, an action based primarily on the risk of birth defects by applicators and other persons with substantial dinoseb exposure (Exttoxnet, 1993).

ESVs or other surface soil guidelines have not been established for these two herbicides.

7.5.4.1.5 Metals

Maximum concentrations of nine metals exceeded their respective ESVs (Table 7-4); these are discussed below.

Aluminum

Aluminum concentrations in all samples exceeded the 50 mg/kg ESV (Table 7-4). Aluminum is considered a COPC only when the soil pH is less than 5.5 (USEPA, 2003a), but soil pH data are not available from Site 1 or other nearby locations. Aluminum is the most commonly occurring metallic element in the earth's crust, and aluminum concentrations in Site 1 soil samples are similar to those at other NCBC Gulfport sites. While there is some degree of uncertainty at Site 1, aluminum probably does not pose site-related risk to plants or soil invertebrates.

Antimony

Antimony was detected in only 2 of 21 samples (Table 7-4); its detected concentrations (1.1 and 3.6 mg/kg) exceeded the 0.27 mg/kg screening value, which is an Eco-SSL for risk to mammals (USEPA, 2005a) rather than risks to plants or soil invertebrates. The antimony Eco-SSL for soil invertebrates is 78 mg/kg. An Eco-SSL for plants is not available, but the ORNL plant toxicity threshold is 5 mg/kg

(Efroymson et al, 1997a). The maximum antimony concentration (3.6 mg/kg) and detection limits in non-detect samples are less than the ORNL and Eco-SSL values. Therefore, antimony is not expected to pose risk to plants or soil invertebrates.

Copper

Copper was detected in 19 of 21 samples (Table 7-4). Only one sample 01SS015 (210 mg/kg) exceeded the 28 mg/kg screening value; the next highest detected concentration was 16.6 mg/kg. The ESV is an Eco-SSL based on risk to avian receptors (USEPA, 2007a) rather than risks to plants or soil invertebrates. The copper Eco-SSLs for plants and soil invertebrates are 70 mg/kg and 80 mg/kg, respectively. Since only one sample had a copper concentration greater than the Eco-SSL values, overall potential risk from copper to plants and soil invertebrates at Site 1 is considered low.

Iron

Iron concentrations exceeded the 200 mg/kg ESV in all 21 surface soil samples (Table 7-4). The ESV is an ORNL value for toxicity to soil micro-organisms but the authors of the ORNL publication state that their confidence in the 200 mg/kg benchmark is low because of the limited data available (Efroymson et al, 1997b). There are no ORNL soil screening values for iron toxicity to plants or earthworms (Efroymson et al, 1997a; 1997b). Iron is an essential element that is required by all forms of life, but toxicity thresholds for earthworms and plants could not be located, and USEPA (2003b) concludes that identifying a specific benchmark for iron in soil is difficult because iron toxicity depends on site-specific soil conditions such as pH, redox potential, and soil-water conditions. Iron is not expected to be toxic to plants in well-aerated soils between pH 5 and 8 (USEPA, 2003b), but soil pH data are not available from Site 1 or other nearby locations. The iron concentrations in Site 1 soil samples are similar to those at other NCBC Gulfport sites. In summary, potential risks to plants or soil invertebrates are uncertain, but are probably not related to activities at the former landfill.

Lead

Lead was detected in all samples and concentrations exceeded the 11 mg/kg ESV in seven samples, with a maximum HQ of 6.4 (Table 7-4). The ESV is an Eco-SSL value that is based on risks to birds instead of risks to plants and soil invertebrates. The lead Eco-SSLs for plants and soil invertebrates are 120 mg/kg and 1,700 mg/kg, respectively (USEPA, 2005b). The maximum concentration of 70.6 mg/kg is less than these guidelines. Therefore, lead poses no risks to plants and soil invertebrates.

Manganese

Manganese was detected in all samples with only sample 01SS017 (358 mg/kg) exceeding the ESV of 220 mg/kg (Table 7-4). The ESV is the eco-SSL value that is based on risks to plants. The Eco-SSL for

risks to soil invertebrates is 450 mg/kg. The plant eco-SSL was exceeded in only one sample generating a low HQ (HQ = 1.6) so any risks to plants are limited to the vicinity of sample 01SS017.

Selenium

Selenium was detected in 4 of 21 samples with three samples having concentrations (0.69 mg/kg, 1 mg/kg, 1.3 mg/kg) exceeding the 0.52 mg/kg screening value (Table 7-4). Its detection limits in non-detect samples (0.61 to 0.78 mg/kg) slightly exceeded the ESV. The ESV is an Eco-SSL value that is based on selenium risks to plants; the Eco-SSL for soil invertebrates is 4.1 mg/kg (USEPA, 2007b). Other screening values for selenium in soil include an ORNL earthworm value of 70 mg/kg (Efroymsen et al, 1997b), an ORNL plant value of 1.0 mg/kg (Efroymsen et al, 1997a), and a Canadian soil quality guideline of 1.0 mg/kg (CCME, 2004). In summary, selenium concentrations indicate no risk to soil invertebrates. The detected selenium concentrations only slightly exceeded the Eco-SSL value for plant toxicity (0.52 mg/kg) and were not high relative to other guidelines, so potential risks are considered negligible.

Vanadium

Vanadium was detected in all samples and concentrations exceeded the 7.8 mg/kg ESV in 13 samples, with a maximum HQ of 2.1 (Table 7-4). The ESV is an Eco-SSL based on risks to birds rather than risks to plants and soil invertebrates. Eco-SSLs for plants and soil invertebrates are not available (USEPA, 2005c), but the Canadian soil quality guideline for vanadium is 130 mg/kg, and is based on toxicity tests using plants and soil invertebrates (EC, 1999; CCME, 2004). The maximum vanadium detection of 16 mg/kg is well below the Canadian guideline. Therefore, impacts to plants and invertebrates from vanadium in soil are not expected.

Zinc

Zinc was detected in all samples, with a maximum HQ of 1.9 (Table 7-4). Zinc concentrations exceeded the 46 mg/kg ESV in two samples: 01SS137 at 89 mg/kg and 01SS10 at 54 mg/kg. The ESV is an Eco-SSL value that is based on risks to birds instead of risks to plants and soil invertebrates. The zinc Eco-SSLs for plants and soil invertebrates are 160 mg/kg and 120 mg/kg, respectively (USEPA, 2007c). Other screening values for zinc in soil include the 100 mg/kg ORNL benchmark for earthworms (Efroymsen et al 1997b) and the Canadian soil quality guideline of 200 mg/kg (CCME, 2004). Zinc concentrations in surface soil are less than guidelines for plants and soil invertebrates; therefore, zinc does not pose risks to plants and soil invertebrates.

7.5.4.1.6 Summary and Conclusions: Surface Soil

Chemicals initially selected as COPCs in the screening process were further evaluated to determine the likelihood that concentrations in surface soil pose risk to soil invertebrates and plants.

Caprolactam was the only SVOC that was a COPC in surface soil. The absence of toxicity data precludes an evaluation of potential impacts to surface soil organisms from caprolactam, which was detected in three surface soil samples.

Several organochlorine insecticides were detected in Site 1 surface soil samples; these pesticides are no longer used but are extremely persistent in soil, and it is unclear whether their concentrations at Site 1 are due to historical use or to landfill wastes. While the majority of surface soil samples were less than the ESV for total organochlorinated pesticides suggesting negligible risks to soil invertebrates, two samples exceeded it. This indicates that potential risks are limited to the vicinity of these two sample locations.

2,4,5-T was detected in 3 of 21 surface soil samples and dinoseb was detected in one of six samples. Surface soil toxicity thresholds have not been established for these herbicides, so there is uncertainty regarding their potential risks to soil invertebrates.

Concentrations of metals tended to be low and pose negligible potential risks to soil invertebrates and plants. Manganese and copper may be associated with elevated potential risk in the vicinity of the single sample locations where each exceeded their respective ESVs.

7.5.4.2 Potential Risk to Aquatic and Benthic Organisms

Benthic invertebrates and aquatic organisms represent different assessment endpoints, and the measurement endpoints used to evaluate risks to these assessment endpoints are different. Specifically, chemical concentrations in sediment are used to evaluate potential risks to benthic invertebrates, while chemical concentrations in surface water are used to evaluate potential risks to aquatic organisms. Nevertheless, they are evaluated together in this section because of the close association between surface water and sediment.

Chemicals that were COPCs in surface water or sediment are discussed below.

7.5.4.2.1 Volatile Organic Compounds

Acetone

USEPA Region 4 ESVs were not available regarding acetone's effects to aquatic and benthic organisms. The toxicity of acetone to animals is in the parts-per-thousand range (Opresko. 1994). Acetone was detected in two of five sediment samples (28 to 220 µg/kg) and in all five surface water samples (3.4 to 5.1 µg/L). Acetone is produced and used as a solvent and chemical intermediate in the manufacture of numerous chemical products, such as oils, waxes, resins, plastics, pharmaceuticals, rubber cement, and

paint and varnish removers. Acetone is typically released into the environment as stack emissions or in wastewater. Acetone also occurs naturally as a metabolic byproduct of plants and animals, and is released into the atmosphere by volcanoes and forest fires. If released into water, acetone will biodegrade (Spectrum, 2003). However, acetone is volatile and tends to biodegrade fairly rapidly, so its presence in sediment and surface water samples at Site 1 is puzzling, unless due to laboratory contamination. Acetone is a common laboratory contaminant sometimes present in environmental samples.

The National Oceanic and Atmospheric Administration (NOAA) has compiled tables of commonly used screening values for environmental media known as the Screening Quick Reference Tables or SQUIRT tables (Buchman, 2008). The SQUIRT tables were reviewed for screening values. Screening values for acetone in the SQUIRT tables include the secondary chronic and acute values calculated by the ORNL (Suter and Tsao, 1996), using methods developed by the USEPA (USEPA, 1993b) for the Great Lakes. The methods developed for calculating secondary, or Tier II, values were designed for instances where there were some acceptable toxicity data for a chemical, but not enough to satisfy the requirements for calculating water quality criteria, or Tier I values. "The Tier II methodology generally produces more stringent values than the Tier I methodology, to reflect greater uncertainty in the absence of additional toxicity data" (USEPA, 1993b). ORNL used methods similar to the USEPA in qualifying toxicological data for inclusion in the Tier II calculations. Both the USEPA and ORNL used primarily effect level values from 48- and 96-hour acute tests to set water quality criteria and secondary values. Chronic values are usually developed from acute values using acute-chronic ratios based on tests incorporating both types of endpoints and performed in a similar manner. ORNL developed an acute Tier II value of 28,000 ug/L and chronic Tier II value of 1,500 ug/L for acetone. All detections of acetone in surface water were much less than the Tier I and II values. The presence of acetone at relatively low concentrations in surface water does not appear to be associated with risk to aquatic organisms.

Carbon Disulfide

Carbon disulfide is used as an industrial and chemical solvent and is also a natural product of anaerobic biodegradation. It is also a common laboratory contaminant used as an extraction solvent. It was detected in only two of five surface water samples, at a relatively low concentration of 0.18 to 0.2 µg/L (Table 7-5). It was not detected in sediment. ORNL developed an acute Tier II value of 17 ug/L and chronic Tier II value of 0.92 ug/L for carbon disulfide (Buchman, 2008). Although toxicity data is sparse regarding its effects to aquatic organisms and plants, the presence of carbon disulfide at relatively low concentrations in surface water does not appear to represent a potential risk to aquatic organisms.

2-Butanone

2-Butanone (also known as methyl ethyl ketone) was detected in four of five sediment samples at low concentrations (5.8 to 80 µg/kg) (Table 7-6). There is no USEPA Region 4 ESV for 2-butanone. The NOAA SQUIRT tables (Buchman, 2008) contain an “intervention” value of 35,000 ug/kg for 2-butanone developed by the Dutch Ministry of the Environment (MVRM, 2000). The Dutch (MVRM, 2000) values typically include a target value, which represents clean soil and sediment, and an intervention value, which represents seriously contaminated soil and sediment. In the case of 2-butanone, however, a target value was not derived (Buchman, 2008). Sediment concentrations of 2-butanone were much less than the intervention value, but since the intervention value is not a toxicity threshold, the potential for toxicity at Site 1 is unclear. 2-butanone is also a common laboratory contaminant. Based on this information, the concentrations of 2-butanone in sediment probably do pose significant risks to benthic invertebrates.

Toluene

Toluene was detected in one of five sediment samples (33 ug/kg) (Table 7-6). An USEPA Region 4 sediment screening is not available. The Dutch Target value for toluene in sediment is 10 ug/kg while the intervention level is 47,000 ug/kg (Buchman, 2008). As mentioned above, the Dutch target value represents clean soil and sediment and the intervention value represents seriously contaminated soil and sediment. In addition, the concentration midway between the target value and the intervention value is designated as an “intermediate” value. The Dutch guidelines specify that concentrations greater than the target value but less than the intermediate value require no further investigation, while further investigation is required when concentrations exceed the intermediate value but are less than the intervention value (Swartjes, 1999). With this in mind, toluene poses negligible risk at Site 1.

1,1,2-Trichlorotrifluoroethane

1,1,2-Trichlorotrifluoroethane was detected in one of five surface water samples at a concentration of 6.6 ug/L (Table 7-5). ORNL developed an acute Tier II value of 5,200 ug/L and chronic Tier II value of 1,200 ug/L for 1,1,2-trichlorotrifluoroethane (Buchman, 2008). The detected concentration is three orders of magnitude less than the lower Tier II value; therefore, 1,1,2-trichlorotrifluoroethane does not pose potential risks to aquatic organisms.

7.5.4.2.2 Semivolatile Organic Compounds

Caprolactam was the only SVOC detected in surface water, and was detected in five of five samples (Table 7-5). In water, caprolactam is not expected to adsorb to suspended solids or to sediments based upon its estimated K_{oc} of 57. Biodegradation in aquatic environments is expected to be extensive. An estimated BCF of 3.2 suggests the potential for bioconcentration in aquatic organisms is low (HSDB, 2009). Based on biodegradation and low bioconcentration potential, any potential risk to aquatic organisms from caprolactam is considered to be low.

Five PAHs (benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, fluoranthene, phenanthrene, and pyrene) were detected in one of five sediment samples (01SD01) (Table 7-6) . Three of the five PAHs had ESVs that were exceeded with a HQ range of 1.1 to 3.9. Two PAHs had no ESVs. The HQ for total PAHs was also low (2.2). Any potential risk from PAHs to benthic invertebrates is considered low and would be isolated around sample location 01SD01.

4-methylphenol was detected in one of five sediment samples (01SD01) at a concentration of 420 ug/kg (Table 7-6). 4-methylphenol is also known as p-cresol. Cresols, including p-cresol are a group of widely distributed natural compounds formed as metabolites of microbial activity and excreted in the urine of mammals. 4-methylphenol is also released to the environment through automobile exhaust and tobacco smoke. If released into water, 4-methylphenol is not expected to adsorb to suspended solids and sediment in the water column based upon log K_{oc} values; it is expected to biodegrade quickly in water under aerobic conditions (HSDB, 2009). The Dutch Target level for 4-methylphenol in sediment is 5.1 ug/kg while the intervention level is 2,600 ug/kg (Buchman, 2008). Thus, 4-methylphenol (p-cresol) appears to represent minimal potential risks (if any) to benthic invertebrates, and any potential risk would be isolated to the single location where it was detected.

Bis(2-ethylhexyl)phthalate was detected in five of five sediment samples and diethyl phthalate was detected in three of five samples (Table 7-6). The Dutch Target level for bis(2-ethylhexyl)phthalate in sediment is less than 100 ug/kg while the intervention level is 10,000 ug/kg (Buchman, 2008). The maximum concentration for bis(2-ethylhexyl)phthalate was 450 ug/kg with a HQ of 2.5 so it appears to represent a low level of potential risk. Sediment screening values and toxicity thresholds were not located regarding diethyl phthalate's effects to benthic invertebrates. The Dutch Target level for diethyl phthalate in sediment is 530 ug/kg while the intervention level is 53,000 ug/kg (Buchman, 2008). There is uncertainty regarding the results for diethyl phthalate as the minimum detection limit was much higher than the reported positively detected concentrations. Phthalates are common environmental contaminants due to their use in plastics. Their presence in sediment at Site 1 might be an artifact of the sampling and/or analytical methods. With a maximum concentration of 220 ug/kg any potential risk from diethyl phthalate to benthic invertebrates is considered negligible.

7.5.4.2.3 Pesticides and Herbicides

No pesticides were detected in surface water above their ESV. Alpha-chlordane and gamma-chlordane were COPCs in sediment because detected concentrations exceeded USEPA Region 4 ESVs in three of five samples (01SD0101, 01SD0401, 01SD0501). Alpha-chlordane had a maximum HQ of 3.5 and gamma-chlordane had a maximum HQ of 2.1 (Table 7-3). Alpha-BHC, delta-BHC, aldrin, and heptachlor epoxide were COPCs in sediment because ESVs were not available (Table 7-3).

Numerous guidelines are available for sediment contaminants, encompassing a wide range of values. MacDonald et al (2003) reviewed and evaluated eight separate approaches to support the establishment of guidelines protective of sediment dwelling organisms in Florida inland waters. Based on the results of that evaluation, threshold effect concentrations (TECs) and probable effect concentrations (PECs) were developed and are used by the Florida Department of Environmental Protection to evaluate risk to sediment dwelling organisms in inland (freshwater) systems. Although developed for Florida freshwater sediments, the MacDonald et al (2003) values are often used to evaluate freshwater sediments in other states, especially when those states have not developed their own TECs and PECs. The TECs identify sediment concentrations below which adverse effects on sediment-dwelling organisms are unlikely to occur, while the PEC values indicate sediment concentrations above which adverse effects on sediment-dwelling organisms are likely to occur (MacDonald et al., 2003). Sediment samples with concentrations between the TEC and PEC are neither predicted to be toxic nor nontoxic. However, sediments which have concentrations of one or more COPCs between the TECs and PECs should be considered to be of moderate priority, while sediments with COPC concentrations in excess of one or more PECs should be considered to be of relatively high concern (MacDonald et al, 2003). Furthermore, the magnitude and frequency of exceedances of the PECs provide a basis for assigning relative priority to areas of concern with respect to contaminated sediments (MacDonald et al, 2003).

As previously discussed, the alpha- and gamma-isomers of chlordane were detected in three sediment samples at relatively low concentrations. All chlordane concentrations were less than the 18 ug/kg PEC. One sample (01SD0101) had a gamma-chlordane concentration (3.5 ug/kg) that slightly exceeded the TEC (3.2 µg/kg). Alpha chlordane concentrations slightly exceeded the TEC in sample 01SD0401 (3.3 ug/kg). Samples 01SD0101 and 01SD0501 had higher concentrations (6 ug/kg and 4.4 ug/kg respectively). The maximum HQ for alpha-chlordane was 3.5 indicating a low level of potential risk; however, this result was “J flagged”. This signifies that the analyte was positively identified but its concentration could not be precisely quantified since it was less than the contract-required quantitation limit but greater than the instrument detection limit.

Sediment toxicity guidelines were not available for aldrin, which was detected only in duplicate sample 01SD0301D at a reported concentration of 0.45 ug/kg. This result was “J flagged”. The original sample 01SD0301 had a result that was reported as 0.4U indicating below detection limits. There is uncertainty, therefore, with these results. NOAA (Buchman, 2008) contains a Lowest Effects Level for aldrin of 2 ug/kg and a Severe Effects Level of 80 ug/kg. Potential risks from aldrin are considered to be negligible.

Sediment toxicity guidelines were not available for the alpha- and delta-isomers of BHC. Alpha-BHC was detected in one sediment sample (0.17 µg/kg) and delta-BHC was detected in one sediment sample

(2.1 µg/kg). The detected concentration of alpha-BHC was less than the lower end of the detection limit, and was “J-flagged”. The detected concentration of gamma-BHC was also “J flagged”. The detected concentrations of both alpha- and delta-BHC were lower than the ESV for gamma-BHC (3.3 µg/kg). Based on this information, potential risk from alpha- and delta-BHC is considered negligible. The fairly low concentrations of alpha- and delta-BHC at Site 1 and their similarity to concentrations at other parts of NCBC Gulfport (i.e. west of Site 3) suggests that their presence is probably due to historical pesticide usage for insect control rather than to landfill-related activities.

Heptachlor epoxide was detected in one of five sediment samples (Table 7-3) at a low concentration (0.46 ug/kg) and was “J flagged”. The TEC for heptachlor epoxide is 2.5 ug/kg (MacDonald et al, 2003). Based on this information, potential risk from heptachlor epoxide to benthic invertebrates is not anticipated.

Silvex was detected in four of five surface water samples at very low concentrations that were “J flagged”. No ESVs or alternate screening values were identified (Table 7-2). In the absence of screening values there is uncertainty as to potential risk associated with Silvex.

7.5.4.2.4 Inorganics

Arsenic and zinc were COPCs in sediment because one sample (01SD0101) had concentrations that exceeded their respective ESVs. Lead exceeded its ESV in two sediment samples (01SD001, and 01SD004) and was retained as a COPC in sediment. Sediment ESVs were not available for aluminum, barium, beryllium, iron, manganese, and vanadium (Table 7-3). In surface water, aluminum, iron, and lead were retained as COPCs because their maximum concentrations exceeded ESVs, while ESVs were not available for barium and manganese (Table 7-2). These COPCs are discussed below.

Aluminum

Aluminum was detected in all surface water samples collected from the east and west ditches at Site 1 with concentrations ranging from 430 ug/L to 1690 ug/L. The maximum HQ was 19.4 in sample 01SW04 collected in the eastern ditch. Aluminum concentrations in the eastern ditch were over two times higher than aluminum concentrations in the western ditch. The 87 µg/L ESV is the National Ambient Water Quality Criteria (AWQC) for aluminum (USEPA, 2004). The aluminum criterion is based on water hardness of <10 mg/L, and USEPA (2004) states that aluminum is substantially less toxic at higher hardness, although the effects are not well quantified. Hardness was not measured in surface water samples collected for this project, but using calcium and magnesium concentrations in sample 01SW04 (the location of the maximum aluminum concentration), water hardness in that sample was 68.3 mg/L when calculated using the following equation from American Public Health Association (APHA, 1998):

$$\text{Hardness, mg equivalent CaCO}_3/\text{L} = 2.497 [\text{Ca, mg/L}] + 4.118 [\text{mg, mg/L}]$$

The 68.3 mg/L hardness value is substantially higher than the 10 mg/L value used to derive the ESV, so the actual toxicity threshold value of aluminum in sample 01SW04 is probably greater than the 87 µg/L ESV, but the precise toxicity threshold value is uncertain.

Aluminum was detected in all five sediment samples, and concentrations ranged from 1,000 to 17,200 mg/kg, with an average of 7,534 mg/kg (Table 7-5). There is no USEPA Region 4 ESV for aluminum in sediment, and no TEC and PEC. The freshwater sediment threshold effect level (TEL) for aluminum in the NOAA SQUIRT tables is 25,500 mg/kg (Buchman, 2008). All sediment concentrations at Site 1 were less than this value, suggesting no potential risk to benthic receptors.

Arsenic

Arsenic was detected in surface water but at concentrations less than its ESV (Table 7-2). Arsenic concentrations in sediment exceeded the sediment ESV in one sample (001SW01) collected from the western ditch at Site 1, with a maximum HQ of 2.7. The arsenic concentration in this sample (19.8 mg/kg) was greater than the TEC of 9.8 mg/kg, and below the 33 mg/kg PEC (Table 7-6). Arsenic concentrations in 14 Mississippi coastal flatwoods soil samples ranged from 0.37 to 14.78 mg/kg, with an average of 4.42 mg/kg (Pettry and Switzer, 2001). All arsenic concentrations except the maximum concentration were within this range. The average arsenic concentration in Site 1 sediment samples was 4.7 mg/kg. Therefore, the arsenic sediment concentrations in Site 1 ditch samples might be due to naturally occurring conditions, but this is uncertain. In summary, arsenic was detected in surface water at concentrations less than its ESV. Sediment concentrations of arsenic exceeded the ESV in only one sample, and all concentrations were within the range reported by Pettry and Switzer (2001). As a result, site-related risks from arsenic are probably minor.

Barium

Barium was detected in all sediment and surface water samples but USEPA Region 4 ESVs were not available. Sediment concentrations exceeded the 20 mg/kg TEC in only one sample, at a maximum concentration of 61.2 mg/kg, which was also slightly more than the 60 mg/kg PEC of MacDonald et al (2003). It should be noted that this sample was “J flagged” so there is some uncertainty associated with this result. The average barium concentration in sediment of 17.6 is less than the TEC. Potential risk to benthic invertebrates from exposure to barium is considered negligible except at the location of the maximum concentration (01SD01).

Surface water concentrations of barium ranged from 21 to 30 ug/L with an average concentration of 27.4 ug/L. The Tier II acute value for barium in freshwater is 110 ug/L while the chronic value is 3.1 ug/L (Buchman, 2008). Potential risk to aquatic organisms from exposure to barium is considered low.

Beryllium

Beryllium was detected in only one of five sediment samples at a concentration of 1.1 mg/kg. No sediment toxicity data were located for beryllium, so its potential toxicity cannot be evaluated. However, it was detected in only on sediment sample and its concentration was not particularly high.

Iron

Iron was detected in all sediment samples, but there is no USEPA Region 4 ESV for iron in sediment, and no TEC and PEC. The freshwater sediment TEL for iron reported by NOAA is 188,400 mg/kg (Buchman, 2008). All sediment concentrations at Site 1 were less than this value.

Iron concentrations in surface water exceeded the 1,000 µg/L ESV, which is the National AWQC, in all five surface water samples with a maximum concentration of 2,410 µg/L and an average concentration of 2,078 µg/L (Table 7-5). It is not clear whether the iron concentrations in the ditches at Site 1 are due to regional conditions, an upstream source, or a combination of these.

It should be noted that the Site 1 surface water data are *total* iron concentrations, not *dissolved* iron concentrations. Concentrations of dissolved metals, rather than total metals, more closely approximate the bioavailable fraction of metals in the water column USEPA (1996a). Since dissolved metal concentrations were not measured in Site 1 surface water, the actual toxicity posed by iron is probably less than that suggested by the maximum HQ of 2.4.

Lead

Lead slightly exceeded its ESV of 30.2 ug/kg in two of five sediment samples (Table 7-6). Sample 01SD0101 had a concentration of 31 ug/kg while sample 01SD0104 had a concentration of 32.1 ug/kg; the maximum HQ was 1.1. The TEC for lead is 35.8 µg/kg, so based on this information the potential risk from lead in sediment is considered negligible.

Lead slightly exceeded its ESV of 1.32 ug/L in two of five surface water samples (01SW0301 and 01SW0401), at concentrations of 1.6 µg/L and 1.7 ug/L respectively. The 1.32 µg/L ESV was the National AWQC when the USEPA Region 4 ESV was promulgated (USEPA, 2001b), but the current National AWQC for lead in freshwater surface water is 2.5 µg/L (USEPA, 2004a). Based on the current AWQC, lead in surface water poses no risks to aquatic receptors.

Manganese

There is no USEPA Region 4 surface water or sediment ESV for manganese, which was detected in all surface water and sediment samples. The freshwater sediment TEL for manganese reported by NOAA is 630 mg/kg (Buchman, 2008). All sediment concentrations at Site 1 were well below this value (Table 7-5).

The chronic screening value reported by NOAA is 80 µg/L for manganese in surface water (Buchman, 2008). All manganese concentrations in surface water at Site 1 were less than 80 µg/L. No potential risk from exposure of aquatic organisms and benthic invertebrates to manganese is anticipated.

Vanadium

Vanadium was not detected in surface water but was detected in all sediment samples. Sediment concentrations ranged from 1.4 to 32.2 mg/kg. An ESV and other toxicity thresholds for vanadium were not available. NOAA SQUIRT tables report a background sediment vanadium concentration of 50 mg/kg (Buchman, 2008). Although the absence of vanadium toxicity data for benthic invertebrates precludes an evaluation of potential risk posed by vanadium in sediment, all sediment concentrations were less than 50 mg/kg, and vanadium was not detected in surface water. Any potential risk posed by vanadium in sediment does not appear to be site-related.

Zinc

Zinc slightly exceeded its ESV of 124 mg/kg in one of five samples. Sample 01SD01 had a zinc concentration of 132 mg/kg yielding a HQ of 1.1. The TEC and PEC for zinc are 120 mg/kg and 460 mg/kg respectively (MacDonald et al, 2003). Based on this information, potential risk to benthic invertebrates is considered low at worst and isolated to the area around sample 01SD01.

7.5.4.2.5 Summary and Conclusions: Sediment and Surface Water

Chemicals initially selected as COPCs in surface water and sediment were further evaluated to determine the likelihood that concentrations pose risk to aquatic and benthic receptors.

Acetone, 2-butanone and toluene were the only VOCs detected in sediment, and acetone, carbon disulfide, and trichlorofluoroethane were the only VOCs detected in surface water. A low level of potential risk from exposure of benthic invertebrates to toluene may be present around sample 01SD01 but overall risk to benthic invertebrates from exposure to VOCs is considered negligible. Likewise, the low levels of VOCs detected in surface water do not appear to represent a potential risk to aquatic organisms.

SVOCs detected in sediment included PAHs, phthalates, and methyl phenol. Any potential risk from PAHs to benthic invertebrates is considered low and if present would be isolated around sample location

01SD01. Bis(2-ethylhexyl)phthalate was found in all sediment samples and appears to represent a low level of potential risk. Potential risk from 4-methyl phenol is considered low and isolated to the single location where it was detected. Caprolactam was the only SVOC detected in surface water. Based on extensive biodegradation and low bioconcentration any potential risk to aquatic organisms is considered low.

Alpha chlordane was the only pesticide and Silvex the only herbicide detected in surface water. Alpha chlordane was detected at a concentration less than its ESV but no ESV was available for Silvex. Silvex was detected in four of five surface water samples at very low concentrations that were "J flagged". In the absence of screening values there is uncertainty as to potential risk associated with Silvex.

Several organochlorine insecticides were detected in sediment. Overall, pesticides appear to pose negligible risks to benthic receptors.

Concentrations of most metals tended to be low and pose negligible potential risks to aquatic and benthic organisms, or do not appear to be related to former activities at the landfill. While most barium concentrations in sediment indicated negligible potential risk, localized potential risk to benthic invertebrates may be present at the maximum concentration location. Barium concentrations in surface water indicate low levels of potential risk to aquatic organisms.

7.5.4.3 Potential Risk to Wildlife via the Food Chain

Food-chain modeling was conducted to evaluate potential risks to representative piscivorous receptors from ingested doses of sediment and surface water COPCs that are known to bioaccumulate or biomagnify. As discussed in Sections 7.1.4 and 7.5.2, the former landfill is covered by fill dirt within an intensively managed landscape including a golf course in the northern portion of the site, and the surface soil exposure pathway for upper trophic level terrestrial receptors such as birds and mammals is incomplete or negligible and insignificant. Thus, food chain modeling was conducted only for piscivorous wildlife receptors. The methods used to model the doses that representative piscivorous receptors could receive, as well as the selection of toxicity reference values (TRVs), are presented in Appendix F.

Based on maximum concentrations and conservative assumptions, food chain HQs exceeded 1.0 for arsenic, lead, and zinc (Table 7-7). NOAEL-based HQs for the green heron were highest for zinc, with an HQ of 2.3. For the mink, the highest NOAEL-based HQ was 1.8 for arsenic. In the average concentration scenario, all food chain HQs were less than 1.0 (Table 7-8). All food chain HQs shown in Tables 7-7 and 7-8 assume an area use factor of 1.0; for example, the representative receptors are assumed to forage exclusively in the water bodies bordering Site 1.

Maximum NOAEL-based food chain HQs for metals in the conservative scenario are not particularly high considering the conservative assumptions used in the food chain model, such as maximum food ingestion rates, minimum body weights, exposure to maximum concentrations, etc. In addition, arsenic concentrations in sediment were within the range reported by Pettry and Switzer (2001), so potential risk from arsenic is probably not site-related. Site-related potential risks from lead and zinc in sediment are considered minor, and the food chain HQs greater than 1.0 for these two metals in the conservative scenario are largely a function of the conservative assumptions used in the food chain model. Note that all HQs for arsenic, lead, and zinc in the average scenario are well below 1.0 (Table 7-8).

Avian LOAELs and NOAELs were not available for aldrin or heptachlor epoxide so potential food chain risks could not be calculated for piscivorous birds. As previously discussed, aldrin was detected only in the duplicate sample of 01SD0301D and was not detected in the original sample of 01SD0301. Heptachlor epoxide was detected in only one of five samples (in the eastern ditch). Piscivorous birds and mammals forage over large areas and would obtain only a small portion of their food from the eastern and western ditches at Site 1. With this in mind, minimal risks to these receptors are anticipated.

7.6 UNCERTAINTY

Uncertainty is associated with all aspects of the ecological assessment methodology presented in the preceding sections. Some uncertainties were discussed in Section 7.5.4. This section provides a summary of the uncertainties, and focuses on those that have not been previously discussed.

The extent to which piscivorous wildlife receptors forage in the ditches at Site 1 is uncertain. All food chain HQs shown in Tables 7-7 and 7-8 and discussed in Section 7.5.4.3 assume an area use factor of 1.0; for example, the representative receptors are assumed to forage exclusively in the water bodies near Site 1. Due to conditions at Site 1, this assumption is overly conservative for piscivorous receptors. The green heron and mink, as well as other piscivorous bird and mammal species, would probably obtain only a portion of their diet from the ditches, resulting in a small exposure to metals, which were responsible for the highest food chain HQs. To be conservative, the ecological risk assessment attempted to err on the side of caution, and specific area-use factors were not estimated.

The extent to which terrestrial wildlife receptors are exposed to site-related soil contamination at the site is uncertain. The site is covered by fill dirt, and terrestrial habitat consists of an intensively managed landscape with very little ground cover. Some wildlife species forage at the site, but even if wildlife are exposed to small areas of site-related soil contamination, such areas would comprise only a miniscule amount of foraging habitat for most wildlife receptors, especially wide-ranging receptors such as birds. With this in mind, the exposure pathway for terrestrial receptors such as birds, mammals, and reptiles is

incomplete or negligible and insignificant, and food chain modeling was not conducted for terrestrial receptors. The resulting uncertainty is believed to be minor.

Laboratory-derived NOAELs and LOAELs might not adequately represent toxicity thresholds for receptors under field conditions. In addition, NOAELs and LOAELs derived for species used in toxicity tests might not adequately represent toxicity thresholds for other species. These uncertainties may overestimate or underestimate potential risks.

Surface water hardness was not measured in Site 1 surface water. Freshwater surface water ESVs for seven metals are based on hardness, and two of those metals (lead, and zinc) were detected in Site 1 surface water. The USEPA Region 4 ESVs used in this evaluation (and shown in Tables 7-2 and 7-5) assume a hardness of 50 mg/L as CaCO₃. Calcium and magnesium concentrations were measured in all five surface water samples at Site 1, and using the average concentrations of calcium and magnesium in those samples, a hardness value of 47.3 mg/L is obtained using the following equation from APHA (1998):

$$\text{Hardness, mg equivalent CaCO}_3/\text{L} = 2.497 [\text{Ca, mg/L}] + 4.118 [\text{Mg, mg/L}]$$

The 47.3 mg/L hardness value closely approximates the 50 mg/L generic value used by USEPA Region 4, so ESVs for lead, and zinc were not adjusted for hardness. The differences in ESVs for hardness of 50 mg/L versus 47.3 mg/L are inconsequential.

Concentrations of dissolved metals were not measured in Site 1 surface water. Instead, the surface water data are concentrations of total metals. This creates some uncertainty in the evaluation of potential risks to aquatic life from iron, since concentrations of dissolved metals more closely approximate the bioavailable fraction of metals in the water column than concentrations of total metals (USEPA, 1996a).

Ecological screening values and toxicity thresholds were not available for some detected chemicals. For example, invertebrate and plant toxicity data were not available for dinoseb in soil. However, dinoseb was detected in only one of five samples, which somewhat reduces the inherent uncertainty for this chemical.

Data for investigating toxicity to reptiles and amphibians from oral ingestion of contaminants are sparse. Thus, potential risks via the food chain were not evaluated for reptiles and amphibians.

Soil samples evaluated in this risk assessment consisted of samples no deeper than 1 foot below the soil surface. However, tree roots extend deeper than 1 foot below the surface, and mammals such as moles could burrow deeper than 1 foot. With the exception of moles and trees, terrestrial species at the site

would probably not be significantly exposed to soils deeper than 1 foot below the surface, so the uncertainty resulting in evaluating only surface soils is negligible.

The source of fill soil used at Site 1 is unknown. There is uncertainty as to whether contaminants detected in surface soil are associated with the former landfill operations or from another source not related to Site 1.

The absence of a base-wide background data set resulted in uncertainty regarding whether some contaminant concentrations were related to Site 1 or were due to natural and/or anthropogenic background conditions.

7.7 SUMMARY AND CONCLUSIONS

Site 1 is a former landfill facility encompassing approximately 9 acres, although the areal extent of the waste disposal is likely much smaller. The landfill was operated from 1942 until 1948, during which time it received solid and chemical waste generated at NCBC Gulfport. In addition to solid wastes, waste fuel, oil, solvents, paint, and paint thinners were transported to the site and buried in trenches. Materials at Site 1 were disposed in trench and fill operations, often accompanied by incineration prior to covering the trenches with soil.

The primary contaminant migration pathway at Site 1 is the infiltration of soil contaminants into groundwater and subsequent seepage into surface water and sediment in the ditches located east and west of the former landfill. Analytical data from surface soil samples collected at the site, and sediment and surface water samples collected from ditches on the eastern and western edges of the site, were evaluated in the ecological risk assessment.

7.7.1 Risks to Soil Invertebrates and Plants

VOCs and SVOCs (with the exception of caprolactam) in surface soil do not pose risks to ecological receptors. The absence of toxicity data precludes an evaluation of potential impacts to surface soil organisms from caprolactam, which was detected in three surface soil samples.

Several organochlorine insecticides were detected in surface soil samples. Concentrations tended to be low, and impacts to ecological receptors from these compounds are not expected. Concentrations in some samples might pose isolated risks to soil invertebrates, but potential risks (if any) might be due to historical use of these insecticides rather than landfill operations. There is uncertainty with this conclusion as a background dataset has not been generated for NCBC Gulfport.

2,4,5-T was detected in 3 of 21 samples and dinoseb was detected in one of six surface soil samples. Surface soil toxicity thresholds have not been established for these herbicides, so there is uncertainty regarding their potential impacts.

Concentrations of metals tended to be low and pose negligible potential risks to soil invertebrates and plants. Copper and manganese may be associated with elevated potential risks in the vicinity of the single sample location where each exceeded its ESV.

7.7.2 Risks to Benthic Invertebrates and Aquatic Organisms

Acetone, 2-butanone and toluene were the only VOCs detected in sediment, and acetone, carbon disulfide, and trichlorofluoroethane were the only VOCs detected in surface water. A low level of potential risk from exposure of benthic invertebrates to toluene may be present around sample 01SD01 but overall risk to benthic invertebrates from exposure to VOCs is considered negligible. Likewise, the low levels of VOCs detected in surface water do not appear to represent a potential risk to aquatic organisms.

Any potential risks to aquatic and benthic receptors at the site from SVOCs are considered low.

Alpha chlordane was the only pesticide and Silvex the only herbicide detected in surface water. Alpha chlordane poses negligible potential risks. Silvex was detected in four of five surface water samples at very low concentrations. In the absence of screening values there is uncertainty as to potential risk associated with Silvex.

Several organochlorine insecticides were detected in sediment. Pesticides appear to pose negligible risks to benthic receptors.

Concentrations of most metals tended to be low and pose negligible potential risks to aquatic and benthic organisms, or do not appear to be related to former activities at the landfill. While barium concentrations in most sediment samples indicated negligible potential risk, potential risk to benthic invertebrates may exist in the vicinity of 01SD01. Iron concentrations in surface water indicate potential risk to aquatic organisms, but it is uncertain as to whether the iron concentrations are the result of Site 1 operations, to another source, or to regional conditions.

7.7.3 Risks to Piscivorous Birds and Mammals

Food-chain modeling was conducted to evaluate potential risks to representative piscivorous receptors from ingested doses of sediment and surface water COPCs that are known to bioaccumulate or biomagnify. Screening-level COPCs in Site 1 sediment and surface water that are known to

bioaccumulate or biomagnify consisted of aldrin, alpha-BHC, delta-BHC, alpha-chlordane, gamma-chlordane, heptachlor epoxide, arsenic, lead, and zinc. Risk via the food chain was evaluated using two scenarios. The first scenario used maximum detected COPC concentrations in sediment and surface water and conservative assumptions for body weight and food consumption. The second scenario used average COPC concentrations, and less conservative values for body weight and food consumption.

Based on maximum concentrations and conservative assumptions, food chain HQs exceeded 1.0 for arsenic, lead, and zinc. NOAEL-based HQs for the green heron were highest for zinc while arsenic had the highest NOAEL-based HQ for the mink. In the average concentration scenario, all food chain HQs were less than 1.0. Based on factors discussed in Section 7.5.4.3, site-related impacts to piscivorous receptors from bioaccumulative COPCs in surface water and sediment are not expected.

Notes

(1) Sample-specific quantitation limits.

(2) Hazard quotient (HQ) = maximum detected concentration ÷ ecological screening value.

(3) An analyte was an ecological chemical of potential concern (COPC) if the maximum detected concentration was greater than the ecological screening value (i.e., HQ>1), or if an ecological screening value was not available. However, calcium, magnesium, and sodium are nutrients that were not considered to be COPCs.

(4) Ecological screening value for beta-BHC.

(5) Ecological screening value for endrin.

NA = Ecological screening value not available.

(1) Sample-specific quantitation limits.

(2) Hazard quotient (HQ) = maximum detected concentration ÷ ecological screening value.

(3) An analyte was an ecological chemical of potential concern (COPC) if the maximum detected concentration was greater than the ecological screening value (i.e., HQ>1), or if an ecological screening value was not available. However, calcium (a nutrient) was not considered to be a COPC.

(4) Ecological screening value for chlordane.

NA = Ecological screening value not available.

8.0 SUMMARY AND CONCLUSIONS

The primary objective of the RI was to provide data to evaluate current environmental conditions and guide the selection of a remedy that is protective of human health and the environment for any contamination present at Site 1. To achieve this primary objective, samples from various media were collected and analyzed to fill data gaps from previous investigations.

The following sections summarize the findings of the RI. The screening criteria used to evaluate the nature and extent of contamination in environmental media at Site 1 included the following:

- MDEQ Tier 1 TRGs
- USEPA Region 9 Preliminary Remedial Goals
- USEPA SSLs for migration to air and groundwater
- USEPA GVCs
- USEPA Region 4 ESVs

The potential impacts of these contaminants to human and ecological receptors were evaluated in the HHRA (based on comparisons to USEPA and state of Mississippi human health benchmarks) and the screening-level ecological risk assessment (based on comparisons to USEPA ESVs).

8.1 SITE HYDROLOGY

Surface water at Site 1 is found in ditches on the eastern and western sides of the site. The drainage ditch on the western side of the site receives surface water runoff from most of the disposal area identified at Site 1 and discharges to Canal No. 1 on the northern side of 8th Street. The canal on the eastern side of Site 1 receives limited runoff from the eastern part of Site 1 and flows to the north and discharges south of 28th Street at Outfall 3.

Groundwater elevations measured in September 2008 indicated groundwater flow in the shallow zone shows a north-south oriented divide near the middle of the site, with groundwater flow to the northwest to the west of the divide and to the northeast to the east of the divide. Groundwater elevation data from the three deep zone wells was plotted and the groundwater flow direction is estimated to be to the northwest.

Groundwater flow velocity was determined from the groundwater elevations measured at the site and slug test data from Sites 3 and 4, which are nearby. The horizontal gradient in the shallow surficial aquifer in the western half of Site 1 was 0.003 ft/ft. With a hydraulic conductivity of 23.5 ft/day, the groundwater flow velocity in this part of Site 1 was 0.24 ft/day. The horizontal gradient in the shallow surficial aquifer in

the eastern half of Site 1 was 0.002 ft/ft. With a hydraulic conductivity of 23.5 ft/day, the groundwater flow velocity in this part of Site 1 was 0.16 ft/day. The horizontal gradient in the deep surficial aquifer at Site 1 was 0.008 ft/ft. With a hydraulic conductivity of 3.2 ft/day, the groundwater flow velocity in this aquifer zone at Site 1 was 0.09 ft/day.

8.2 SOIL ASSESSMENT

The results of the soil analytical program are consistent with the containment strategy of the presumptive remedy, and the direct observation of the field samples confirmed the waste disposal area defined by the geophysical investigation.

The following chemicals were retained as surface soil COPCs for the risk assessments:

- Direct Exposure (carcinogen) – dieldrin and arsenic
- Direct Exposure (non-carcinogen) – aluminum, antimony, cobalt, iron, and manganese
- Leaching to groundwater – tetrachloroethene, benzo(b)fluoranthene, Aroclor-1260, aldrin, alpha chlordane, BHC isomers, dieldrin, heptachlor epoxide, antimony, arsenic, chromium, cobalt, iron, lead, manganese, and selenium
- Ecological Receptors – aldrin, gamma BHC, dieldrin, endrin aldehyde, aluminum, antimony, copper, iron, lead, manganese, selenium, vanadium, and zinc
- Ecological Receptors (No ESV) – 2-butanone, 4-methyl-2-pentanone, caprolactam, chlordane, endosulfan II, endosulfan sulfate, heptachlor, heptachlor epoxide, methoxychlor, 2,4,5-T, and dinoseb

The following chemicals were retained as subsurface soil COPCs for the HHRA:

- Direct Exposure (carcinogen) – Aroclor-1242 and arsenic
- Direct Exposure (non-carcinogen) – aluminum
- Leaching to groundwater – alpha chlordane, Aroclor-1242, beta BHC, delta BHC, dieldrin, heptachlor epoxide, arsenic, chromium, and iron

The containment presumptive remedy strategy for Site 1 includes the installation and maintenance of a soil cover system. Strategically covering the existing surface will remove important exposure pathways including direct exposure to surface soil by ecological receptors, potential leaching of contaminants from soil to groundwater, and erosion and transport of surface soil from the landfill. Direct exposure to subsurface soil will be prevented by institutional controls established to maintain the integrity of the cover.

8.3 GROUNDWATER ASSESSMENT

Groundwater characterization samples collected at Site 1 were analyzed for TCL, TAL, and Appendix IX analytes. Groundwater delineation samples were collected using DPT and analyzed for selected VOCs.

The following chemicals were retained as groundwater COPCs for the HHRA:

- Direct Exposure (carcinogen) – tetrachloroethene, trichloroethene, naphthalene, and arsenic
- Direct Exposure (non-carcinogen) – iron, manganese, and thallium
- Volatilization from groundwater – tetrachloroethene and trichloroethene

The interaction between the layers of sandy and clayey silt and the contaminants at the site appears to have created a vertical barrier to migration. Although not a true aquaclude, these lower permeability layers restrict the movement of contaminants such that the containment strategy of a soil cover should be effective in reducing future migration of contaminants and will be evaluated in the FS.

8.4 SURFACE WATER AND SEDIMENT ASSESSMENT

The concentrations of organic compounds (VOCs, SVOCs, pesticides, PCBs, and herbicides) reported in the surface water samples collected at Site 1 were less than the human health screening criteria; therefore, none of the organic compounds were retained as COPCs for the HHRA. The organic compounds detected in surface water samples at Site 1 that do not have established ESVs (1,1,2-trichlorofluoroethane, acetone, carbon disulfide, caprolactam, and Silvex) were retained as COPCs for the SLERA.

Arsenic was detected in one surface water sample at a concentration greater than the RSL tap water criteria and is retained as a COPC in the HHRA. Iron concentrations in all the surface water samples were less than the TRGs and RSL.

Aluminum, iron and lead were reported in Site 1 surface water samples at concentrations greater than the ESVs and are retained as ecological COPCs. Barium and manganese were retained as COPCs for the SLERA because ESVs have not been established for these metals.

The following chemicals were retained as sediment COPCs for the risk assessments:

- Direct Exposure (carcinogen) – benzo(a)pyrene, benzo(b)fluoranthene, and arsenic
- Direct Exposure (non-carcinogen) – aluminum, iron, and manganese
- Ecological Receptors – chrysene, fluoranthene, phenanthrene, pyrene, bis(2-ethylhexyl)phthalate, and chlordane
- Ecological Receptors (No ESV) – 2-butanone, acetone, toluene, aldrin, 4-methylphenol, diethyl phthalate, benzo(b)fluoranthene, benzo(k)fluoranthene, BHC isomers, heptachlor epoxide, aluminum, barium, beryllium, iron, manganese, and vanadium

These results suggest that the contaminant levels reported in Site 1 surface water and sediment samples reflect base-wide conditions and do not result from releases from the landfill at Site 1.

8.5 MEDIA TO AIR MIGRATION PATHWAY

Air samples were not collected from Site 1 during the RI because the concentrations of volatile contaminants previously detected in soil and groundwater were relatively low. Air monitoring for workers was conducted as part of the site investigation activities as a health and safety precaution to identify potential exposure to concentrations of volatile contaminants. The passive soil gas survey detected only the limited occurrence of VOCs.

To determine the potential for migration of soil contaminants to the atmosphere, contaminant concentrations were compared to USEPA SSLs. SSLs have been established for various volatiles, pesticides/PCBs, and metals. Concentrations of these classes of analytes that were detected in soil at Site 1 were less than the default SSL values.

USEPA GVCs have been established for many of the VOCs detected in groundwater at Site 1. Tetrachloroethene and trichloroethene were detected in one or more groundwater samples at concentrations greater than the default criteria, indicating the potential for migration and accumulation of vapors from the groundwater into the atmosphere.

8.6 HUMAN HEALTH RISK ASSESSMENT

The HHRA was performed to evaluate exposure to COPCs in subsurface and surface soil, groundwater, surface water, and sediment at Site 1. Estimated risks for construction/excavation workers and adult trespassers assumed to be exposed to COPCs in site media were less than or equal to USEPA and MDEQ risk management benchmarks. The quantitative risk evaluation indicated that risk estimates for the site maintenance worker and adolescent trespasser were only marginally greater than the MDEQ benchmark. Additionally, although the total ILCR for the site industrial worker exceeds the MDEQ cancer benchmark, the risk estimate is within one order of magnitude of the MDEQ benchmark and is primarily due to PCBs and dieldrin in soil, which may be attributable to the limited presence of contamination hot spots.

The quantitative risk evaluation also indicated that potential adverse health effects may be associated with the hypothetical future residential use of groundwater. The maximum detected concentration of tetrachloroethene in groundwater exceeded the ORNL RSL for tap water, and the maximum concentration of arsenic in groundwater exceeded both the ORNL tap water RSL and the MDEQ groundwater TRG. However, there is considerable uncertainty in the risk estimates calculated for exposure to COPCs in groundwater, and the numerical risk results are likely overestimated. In addition, the residential groundwater use scenario is evaluated to be conservative and to provide information to risk managers for Site 1. The groundwater underlying and downgradient of Site 1 is not currently used as a source of drinking water and there are no plans to develop this resource in the future. Residential cancer risk estimates slightly exceeded the MDEQ benchmark for soils (for both adult and child residents) due to dieldrin, arsenic, and PCBs. However, arsenic is within published background levels for soil. Sediment also exceeded the MDEQ cancer benchmark for the child resident only due to arsenic. Residential risks estimated for surface water did not exceed USEPA and MDEQ risk management benchmarks.

8.7 ECOLOGICAL RISK ASSESSMENT

The primary contaminant migration pathway at Site 1 is the infiltration of soil contaminants into groundwater and subsequent seepage into surface water and sediment in the ditches located east and west of the former landfill. Analytical data from surface soil samples collected at the site, and sediment and surface water samples collected from ditches on the eastern and western edges of the site, were evaluated in the ecological risk assessment.

VOCs and SVOCs (with the exception of caprolactam) in surface soil do not pose risks to ecological receptors. Several organochlorine insecticides were detected in surface soil samples. Concentrations tended to be low, and impacts to ecological receptors from these compounds are not expected. 2,4,5-T

was detected in 3 of 21 samples and dinoseb was detected in one of six surface soil samples. Surface soil toxicity thresholds have not been established for these herbicides, so there is uncertainty regarding their potential impacts. Concentrations of metals tended to be low and pose negligible potential risks to soil invertebrates and plants.

Acetone, 2-butanone and toluene were the only VOCs detected in sediment, and acetone, carbon disulfide, and trichlorofluoroethane were the only VOCs detected in surface water. A low level of potential risk from exposure of benthic invertebrates to toluene may be present around sample 01SD01 but overall risk to benthic invertebrates from exposure to VOCs is considered negligible. Likewise, the low levels of VOCs detected in surface water do not appear to represent a potential risk to aquatic organisms. Pesticides appear to pose negligible risks to benthic receptors.

Concentrations of most metals tended to be low and pose negligible potential risks to aquatic and benthic organisms, or do not appear to be related to former activities at the landfill. While barium concentrations in most sediment samples indicated negligible potential risk, potential risk to benthic invertebrates may exist in the vicinity of 01SD01. Iron concentrations in surface water indicate potential risk to aquatic organisms.

Based on maximum concentrations and conservative assumptions, food chain HQs exceeded 1.0 for arsenic, lead, and zinc. NOAEL-based HQs for the green heron were highest for zinc while arsenic had the highest NOAEL-based HQ for the mink. In the average concentration scenario, all food chain HQs were less than 1.0; therefore, site-related impacts to piscivorous receptors from bioaccumulative COPCs in surface water and sediment are not expected.

8.8 CONCLUSIONS

Based on the results of the RI, an FS using CERCLA guidelines is recommended for Site 1. As discussed throughout this report, Site 1 meets the requirements of the presumptive remedy framework for municipal and military landfills. Therefore, the primary remedial strategy for Site 1 will be containment of the disposal area with a soil cap meeting state and USEPA requirements to prevent exposure to site soil.

The containment strategy should focus on three areas: (1) soil cover to prevent direct exposure to landfill materials; (2) elimination of the potential for mechanical disturbance of the cover during site operations; and (3) minimization of erosion of surface soil.

Based on the locations and types of chemicals detected during this investigation, interim removal or time-critical actions will not be required. After the above actions are taken, there will be a low likelihood for the

migration of contaminated media, and the local population will not be exposed to contaminants in subsurface soil and groundwater at the site if current base operations and restrictions are maintained.

The FS will incorporate the presumptive remedy strategy including the soil cover to prevent recontamination in the future. The current soil cover is not likely to be adequate for permanent site closure under either MDEQ or USEPA regulations. Long-term monitoring and maintenance of the soil cover will be required.

APPENDIX A
GEOPHYSICAL SURVEY REPORT

1.0 INTRODUCTION

This report has been prepared by Tetra Tech NUS, Inc. (TtNUS) on behalf of the United States Navy, Naval Facilities Engineering Command (NAVFAC) Southeast under the Comprehensive Long-Term Environmental Action Navy (CLEAN) Contract Number N62467-04-D-0055, Contract Task Order (CTO) 0065. This report summarizes geophysical surveys performed from January 9 through January 16, 2008 by Tetra Tech, at Site 1 within the Naval Construction Battalion Center (NCBC) in Gulfport, Mississippi. Figure 1-1 shows the general location of the complex.

1.1 SITE BACKGROUND

The NCBC is an approximately 1,100 acre facility used to provide military readiness for battalions of the Naval Construction Force, and to provide property to store and maintain pre-positioned war reserve material. Site 1 (on the installation) is currently defined as an approximately 16 acre area shown on Figure 1-2. The site limits have expanded significantly over time based on previous findings and investigations. Site 1 is used as a training ground for mock disaster recovery operations. Several buildings are present, providing classrooms and enclosed training exercise areas. Most of Site 1 however, is fairly flat, open terrain with a moderate amount of tree cover. The site is well maintained, and the ground surface consists mostly of mowed grass and small paved portions. A few underground utilities (some non-metallic) are present.

Previously, Site 1 was used as an unlined landfill for receiving solid and chemical wastes reportedly in 55 gallon drums from 1942 to 1948, when it was closed and covered by a layer of soil. In 1984 four or five drums were reportedly encountered during a water line repair. In 1987 a geophysical survey was conducted, and the report concluded that large areas of disturbed ground were present at the site. More specific information, delineation of possible locations of drum cache disposals, was requested, and prompted Tetra Tech's geophysical surveys documented in this report.

The adjacent golf course portion north of Site 1 was also prospected with a reconnaissance meandering path geophysical survey to confirm non-anomalous readings outside of Site 1. This section of the golf course formerly contained catfish ponds that were subsequently filled in to build the golf course, and reportedly clean fill was used for this process.

2.0 PERSONNEL

A TtNUS Project Geophysicist from the Pittsburgh office (James Coffman) assisted by Tetra Tech personnel from the Tallahassee office performed the fieldwork from January 9 to 16, 2008.

TtNUS personnel met the medical, training experience, and educational requirements specified in the United States Army Corps of Engineers (USACE) DID OE-025.02, and Chapter 29 Code of Federal Regulations 1910.120.

3.0 OBJECTIVES AND SCOPE

The geophysical objective was to locate buried metal anomalies that could represent small to large drum cache disposals within the accessible portions of Site 1. The geophysical methods employed detect, but do not identify, buried metallic objects. In simple cases where the expected types of buried objects are limited, a guess can sometimes be made as to what might be buried at an anomaly location. Such cases are generally rare on developed sites within military bases because these sites often had mixed uses throughout their histories and consequently, any number of buried object types may be present.

4.0 EQUIPMENT

TtNUS conducted the geophysical surveys using a Geonics EM31 model MK2 and Geometrics G-858 and G-856 magnetometer instruments in the accessible portions of Site 1.

The Geonics EM31 is a frequency domain electromagnetic (EM) instrument. The EM31 generates a primary electromagnetic field, and secondary EM fields are measured as a function of frequency allowing stark differences in terrain conductivity to be differentiated. Two measurement components are typically recorded; quadrature-phase (QP) and in-phase (IP). The QP component is sensitive to metal and non-metal components of the ground, and the IP component is predominantly sensitive to metal. The instrument can be operated in horizontal or vertical dipole mode, which nominally measure 9 or 18 foot depths, respectively. The EM31 was set to acquire data 5 times per second, and operated in the vertical dipole mode.

The G-858 and G-856 magnetometers measure the Earth's magnetic field at selected time increments. Both magnetometer instruments are only capable of detecting ferrous metal. The G-858 was used to collect data across the site, and the G-856 was used to collect stationary background readings to correct the G-858 data for potential magnetic field spikes that might occur from increased or decreased solar activity (diurnal changes). As magnetic bodies above and below ground add or subtract to the Earth's magnetic field, anomalies can be identified by the increases and decreases measured. Diurnal changes in the Earth's magnetic field must be accounted for to correct for potential data shifts that might otherwise be attributed to these survey anomalies (ferrous metal objects). The G-858 instrument was used to automatically record five readings per second from a single sensor, and the base station (G-856) was set up to acquire readings every 60 seconds.

A Trimble Ag 114 DGPS (equipped to receive Omnistar and WAAS differential corrections) was used to accurately locate data stations (sub-meter accuracy). This global positioning system (GPS) unit was integrated in real time with the EM31 and G-858 once per second during survey acquisition.

5.0 GEOPHYSICAL SURVEY

A survey grid (20-foot spaced pin flags) was established in Site 1 to serve as a guide for conducting EM31 and G-858 surveys using 10-foot spaced survey lines oriented north-south across the accessible portions of the site and beyond. The 10-foot survey line spacing provides thorough detection capabilities for small to large caches of drums; however, individual buried drums or small objects could escape detection if located between survey lines. The site is currently defined as approximately 16 acres, and the geophysical survey was expanded north beyond these limits to encompass a total of about 19 acres. Several buildings and obstructions created gaps in survey data, and these gaps are presented as white-blanked or annotated areas in the survey plot. The adjacent golf course was surveyed with a meandering path survey where the predominant survey direction was in the east-west direction.

Prior to field acquisition, the equipment was set up according to manufacturer's recommendations (calibrations and operational checks, and instrument null). Geophysical data were acquired at a rate of five readings per second (corresponding to approximately one reading per foot given the walking pace with the instrument). GPS readings were real-time integrated with the geophysical data every second.

6.0 RESULTS AND DISCUSSION

The accessible portions of Site 1 were surveyed with EM31 and G-858 geophysical instruments using a 10-foot survey line spacing, selected to provide thorough detection capabilities for small

to large caches of drums. High accuracy data positioning was provided via real-time GPS integration (sub-meter accuracy). The data collected are displayed in color contour maps superimposed on a site plan, and displayed in Figures 6-1 (EM31 Quadrature-Phase), Figure 6-2 (EM31 In-Phase) and 6-3 (Total Magnetic Field). Figure 6-4 is a comprehensive interpretation of all the geophysical data superimposed on the EM31 in-phase plot.

Data contouring was performed using Geosoft's Oasis montaj software (v. 6.4.2, 2007 release). Background levels are shown by green to light green color contours on the plots. Anomalies are evident in response values greater and less than these background levels (ranging from blue to light blue and also yellow to pink colored contours), and the color bar shown on the figure provides an indication of the amplitude of the displayed anomalies. The anomaly response from a particular object is not unique, in that the depth of burial will affect the same object's response values.

Anomaly response was recorded near buildings and other noted aboveground metallic objects shown on the figures, and the presence or absence of subsurface objects in those areas cannot be determined from the geophysical data alone.

Numerous anomalies from small to large are interpreted from the contour data. Larger anomalies, possibly attributed to a cluster or cache of buried objects or to a single large buried item are shown on Figure 6-4 by a hatched pattern labeled with a number or letter. Numbered anomalies represent the largest anomalies (referred to as large anomalies), and all contain at least a significant portion of ferrous material (EM and magnetic anomalies are associated). Because of their size and amplitude, these anomalies represent the highest probability of possible drum disposal areas. Lettered anomalies are smaller (referred to as medium-sized anomalies), though still significant in size and amplitude, and any of these hatched anomalies could potentially represent small drum disposal caches (ferrous component is associated with each of these anomalies). The smallest interpreted anomalies, possibly attributed to an individual small item or small amounts of buried metal, are shown by a shaded square symbol followed by a number, and anomalies 1, 4 and 5 appear to have a ferrous component. These smaller anomalies are judged to be too small in size and amplitude to represent even small caches of drums, but still could represent significant small individual items.

All of the largest (numbered) anomalies were located and marked in the field, and some of the medium-sized (lettered) anomalies were also marked in the field (B, C, E and G marked). Please note that all medium sized anomalies are judged to be significant, not just the selected ones marked in the field. Tables 6-1 through 6-3 display State Plane coordinates for large, medium and small anomalies, respectively, to provide location information in the event that site surface features are removed.

Several linear anomalies were detected and are interpreted as possible underground metallic utilities or utility ducts (shown by a dashed line symbol on Figure 6-4). Neither of the two survey instruments can detect a non-metallic utility, nor was utility locating a specific objective of the project. One short linear anomaly off the southwest corner of Building 109 was interpreted in-field from the magnetometer data as a medium-sized hatched anomaly; however, upon further review (using the EM data in conjunction) the anomaly is interpreted as a possible section of pipe, and is consequently shown by a dashed line symbol labeled with the letter "G" on Figure 6-4. Please note that this anomaly was marked in-field along with the other medium-sized (lettered) anomalies interpreted in the field.

Figure 6-5 displays the EM31 in-phase response of the meandering path reconnaissance geophysical survey of the golf course area. The objective here was to reconnoiter the area to determine whether there is evidence of buried metal disposal in the vicinity of the former catfish ponds shown on Figure 6-5. A single meandering path survey (one survey line) was conducted by walking back and forth along the long axis of the golf course to reconnoiter the catfish pond areas. The data indicate few anomalies; primarily where the golf cart paths, which appear to be

reinforced, were crossed. One moderate amplitude anomaly was detected in the southeast corner of the meandering path, and a small quantity of buried metal may be associated. Otherwise, low EM response was recorded along the remainder of the survey path indicating the absence of significant buried metal.

GORE™ EXPLORATION SURVEY
GORE™ ENVIRONMENTAL SURVEY

April 22, 2008

Robert Fisher
Tetra Tech NUS
3360 Capital Circle NE
Suite B
Tallahassee, FL 32305

Site Reference: Site 1 – NCBC Gulfport
Gore Production Order Number: 13462081

Dear Mr. Fisher:

Thank you for choosing a GORE™ Survey.

The attached package consists of the following information (in duplicate):

- **Final report**
- **Chain of custody and analytical data table (included in Appendix A)**
- **Stacked total ion chromatograms (included in Appendix A)**

Please contact our office if you have any questions or comments concerning this report. We appreciate this opportunity to be of service to Tetra Tech, and look forward to working with you again in the future.

Sincerely,
W.L. Gore & Associates, Inc.

Hilary G. Trethewey
Environmental Project Manager

GORE™ Surveys - Final Report

REPORT DATE: 04/22/2008

AUTHOR: HGT

SITE INFORMATION

Site Reference: Site 1 – NCBC Gulfport

Gore Production Order Number: 13462087

Gore Site Code: EFN

FIELD PROCEDURES

Modules shipped: 33

Installation Date(s): 3/18 /2008

Modules Installed: 32

Field work performed by: Tetra Tech

Retrieval date(s): 4/3/2008

Modules Retrieved: 24

Modules Lost in Field: 8

Modules Not Returned: 0

Exposure Time: 16 [days]

Trip Blanks Returned: 1

Unused Modules Returned: 0

Date/Time Received by Gore: 4/8/2008 2:00 PM **By:** CW

Chain of Custody Form attached: Yes

Chain of Custody discrepancies: None

Comments:

Module 560095 was identified as a trip blank.

Modules 560060 – 064 and 560089, 560090 and 560094 were noted as “destroyed” and are considered lost in the field.

GORE™ Surveys - Final Report

ANALYTICAL PROCEDURES

W.L. Gore & Associates' Screening Module Laboratory operates under the guidelines of its Quality Assurance Manual, Operating Procedures and Methods. The quality assurance program is consistent with Good Laboratory Practices (GLP) and ISO Guide 25, "General Requirements for the Competence of Calibration and Testing Laboratories", third edition, 1990.

Instrumentation consists of state of the art gas chromatographs equipped with mass selective detectors, coupled with automated thermal desorption units. Sample preparation simply involves cutting the tip off the bottom of the sample module and transferring one or more exposed sorbent containers (sorbent, each containing engineered adsorbents) to a thermal desorption tube for analysis. Sorbent remain clean and protected from dirt, soil, and ground water by the insertion/retrieval cord, and require no further sample preparation.

Analytical Method Quality Assurance:

The analytical method employed is a modified EPA method 8260/8270. Before each run sequence, two instrument blanks, a sorbent containing 5µg BFB (Bromofluorobenzene), and a method blank are analyzed. The BFB mass spectra must meet the criteria set forth in the method before samples can be analyzed. A method blank and a sorbent containing BFB are also analyzed after every 30 samples and/or trip blanks. Standards containing the selected target compounds at five calibration levels are analyzed at the beginning of each run. The criterion for each target compound is less than 25% RSD (relative standard deviation). If this criterion is not met for any target compound, the analyst has the option of generating second- or third-order standard curves, as appropriate. A second-source reference standard, at a level of 10µg per target compound, is analyzed after every ten samples and/or trip blanks, and at the end of the run sequence. Positive identification of target compounds is determined by 1) the presence of the target ion and at least two secondary ions; 2) retention time versus reference standard; and, 3) the analyst's judgment.

NOTE: All data have been archived. Any replicate sorbent not used in the initial analysis will be discarded fifteen (15) days from the date of analysis.

Laboratory analysis: thermal desorption, gas chromatography, mass selective detection

Instrument ID: # 8 **Chemist:** DC/DD

Compounds/mixtures requested: A1

Deviations from Standard Method: None

Comments: Soil vapor analytes and abbreviations are tabulated in the Data Table Key (page 6).

GORE™ Surveys - Final Report

DATA TABULATION

CONTOUR MAPS ENCLOSED: none

NOTE: All data values presented in Appendix A represent masses of compound(s) desorbed from the GORE™ Modules received and analyzed by W.L. Gore & Associates, Inc., as identified in the Chain of Custody (Appendix A). The measurement traceability and instrument performance are reproducible and accurate for the measurement process documented. Semi-quantitation of the compound mass is based on a five-level standard calibration.

General Comments:

- This survey reports soil gas mass levels present in the vapor phase. Vapors are subject to a variety of attenuation factors during migration away from the source concentration to the module. Thus, mass levels reported from the module will often be less than concentrations reported in soil and groundwater matrix data. In most instances, the soil gas masses reported on the modules compare favorably with concentrations reported in the soil or groundwater (e.g., where soil gas levels are reported at greater levels relative to other sampled locations on the site, matrix data should reveal the same pattern, and vice versa). However, due to a variety of factors, a perfect comparison between matrix data and soil gas levels can rarely be achieved.
- Soil gas signals reported by this method cannot be identified specifically to soil adsorbed, groundwater, and/or free-product contamination. The soil gas signal reported from each module can evolve from all of these sources. Differentiation between soil and groundwater contamination can only be achieved with prior knowledge of the site history (i.e., the site is known to have groundwater contamination only).
- QA/QC trip blank modules were provided to document potential exposures that were not part of the soil gas signal of interest (i.e., impact during module shipment, installation and retrieval, and storage). The trip blanks are identically manufactured and packaged soil gas modules to those modules placed in the subsurface. However, the trip blanks remain unopened during all phases of the soil gas survey. Levels reported on the trip blanks may indicate potential impact to modules other than the contaminant source of interest.

GORE™ Surveys - Final Report

- Unresolved peak envelopes (UPEs) are represented as a series of compound peaks clustered together around a central gas chromatograph elution time in the total ion chromatogram. Typically, UPEs are indicative of complex fluid mixtures that are present in the subsurface. UPEs observed early in the chromatogram are considered to indicate the presence of more volatile fluids, while UPEs observed later in the chromatogram may indicate the presence of less volatile fluids. Multiple UPEs may indicate the presence of multiple complex fluids.
- Stacked total ion chromatograms (TICs) are included in Appendix A. The six-digit serial number of each module is incorporated into the TIC identification (e.g.: 123456S.D represents module #123456).

Project Specific Comments:

- No target compounds were detected on the trip blanks and/or the method blanks. Thus, target analyte levels reported for the field-installed modules that exceed trip and method blank levels, and the analyte method detection limit, are more likely to have originated from on-site sources.
- If the objective of the soil gas survey was to delineate the nature and extent of the contamination, then additional soil gas sampling is recommended in those areas where the color contours appear to extend into unsampled areas.

GORE™ Surveys - Final Report

KEY TO DATA TABLE Site 1 – NCBC Gulfport

UNITS

µg	micrograms (per sorber), reported for compounds
MDL	method detection limit
bdl	below detection limit

PURGE DATA:

Table with columns: Date, Volume, pH, S.C., Temp., Turbidity, DO, Salinity, Other. Includes handwritten notes like 'm skin' and 'ORD'.

Handwritten calculations on the left margin: 2.80, 2.77, 10.23, 1.02, .51, .10, 11.63, 0.4

SAMPLE COLLECTION INFORMATION:

Table with columns: Analysis, Preservative, Container Requirements, Collected. Includes entries for VOC, SVOC, Pest, PCB, Herb, and TAL Metals.

OBSERVATIONS / NOTES:

Large empty box for observations and notes.

Circle if Applicable:

APPENDIX D

VALIDATED LABORATORY DATA

TO: R. FISHER **DATE:** JANUARY 6, 2009
FROM: JOSEPH KALINYAK **COPIES:** DV FILE
SUBJECT: ORGANIC DATA VALIDATION – VOC/SVOC/PEST/PCB/HERB
NCBC GULFPORT CTO 0065
SAMPLE DELIVERY GROUP (SDG) GULFPORT – 012
SAMPLES: 14/Aqueous/VOC/SVOC/PEST/PCB/HERB

01SBDIT01	01SBDIT02	01SBDIT03
01SS01401	01SS01401DUP	01SS01501
01SS01701	01SS02401	01SS02501
01SS13701	01SS13801	01SS13901
01SS13901DUP	01SS42001	

Overview

The sample set for CTO 0065, NCBC Gulfport, SDG Gulfport-012, consists of fourteen (14) soil environmental samples including two (2) field duplicate pairs, 01SS01401/01SS01401DUP and 01SS13901/ 01SS13901DUP, included in this sample delivery group.

All samples were analyzed for volatile organic compounds (VOC), semi-volatile organic compounds (SVOC), organochloride pesticides (PEST), polychlorinated biphenyls (PCB), and herbicides (HERB). The samples were collected by Tetra Tech NUS on September 30 and October 1, 2008 and analyzed by Empirical Laboratories, LLC. All analyses were conducted in accordance with Naval Facilities Engineering Service Center (NFESC) Quality Assurance/Quality Control (QA/QC) criteria using USEPA SW-846 Methods 8260B, 8270C, 8081A, 8082 and 8151A analysis and reporting protocols. The data contained in this SDG were validated with regard to the following parameters:

- * ● Data completeness
- * ● Hold times
- * ● GC/MS Tuning
- Initial/continuing calibrations
- Laboratory method blank results
- Surrogate Recoveries
- Blank Spike/Blank Spike Duplicate Results
- Matrix Spike/Matrix Spike Duplicate Results
- * ● Internal Standards
- * ● Field Duplicate Precision
- * ● Compound Quantitation
- * ● Compound Identification
- * ● Detection Limits

The symbol (*) indicates that quality control criteria were met for this parameter. Problems affecting data quality are discussed below; documentation supporting these findings is presented in Appendix C. Qualified Analytical results are presented in Appendix A. Results as reported by the laboratory are presented in Appendix B.

To: R. Fisher
Page: 2

Volatiles - VOC

The following compounds were detected in the laboratory method blanks for the associated samples in SDG Gulfport-012:

<u>Compound</u>	<u>Maximum Concentration</u>	<u>Blank Action Level</u>
Acetone ⁽¹⁾	2.9 µg/kg	29.0 µg/kg
Toluene ⁽¹⁾	0.64 µg/kg	3.20 µg/kg
1,2,3-Trichlorobenzene ⁽¹⁾	0.36 µg/kg	1.80 µg/kg
1,2,4-Trichlorobenzene ⁽¹⁾	0.31 µg/kg	1.55 µg/kg
Methylene chloride ⁽²⁾	4.8 µg/kg	48.0 µg/kg

⁽¹⁾ Maximum concentration present in the laboratory method preparation blank V4BLK1002 affecting all SDG samples.

⁽²⁾ Maximum concentration present in the laboratory method preparation blank V4BLK1003 affecting all SDG samples.

An action level of 10X the maximum contaminant concentration for the common laboratory contaminants acetone and methylene chloride and 5X the maximum contaminant concentration for all other contaminants was established to evaluate laboratory contamination. Dilution factors, sample aliquots and percent solids for soils were taken into consideration during the application of all action levels. Only the maximum method blank result for the VOC contaminants was used for this evaluation. The positive results for the contaminants below the blank action level were qualified as non-detected, (U).

The continuing calibration %D was greater than 25% the quality control limit for acetone for instrument VOA4 on 10/02/08 @ 12:00 affecting samples 01SS01701, 01SS42001, 01SS01401, 01SS01401DUP, 01SS01501, 01SS02401, 01SS02501, 01SS13701, 01SS13801, and 01SS13901DUP. The non-detected results reported for acetone for the associated samples were qualified as estimated, (UJ), except for those samples previously qualified due to laboratory blank contamination.

The continuing calibration %D was greater than 25% the quality control limit for acetone and 1,2-dichloroethane for instrument VOA4 on 10/03/08 @ 10:28 affecting samples 01SS13901, 01SBDIT01, 01SBDIT02, and 01SBDIT03. The non-detected results reported for acetone and 1,2-dichloroethane for the associated samples were qualified as estimated, (UJ), except for acetone results for those samples previously qualified for acetone due to laboratory blank contamination.

A laboratory control sample duplicate (LCS/D) had a % recovery above the QC limits for 1,2-dichloroethane. No action was taken because the laboratory control sample (LCS) % recovery for 1,2-dichloroethane was within the quality control limits and all samples results were non-detected.

The matrix spike (MS) /matrix spike duplicate (MSD) pair associated with sample 01SS02501 had % recoveries below the quality control limit for the MS 1,2,4-trichlorobenzene result and also the MSD chlorobenzene result. The MSD 1,2,4-trichlorobenzene and MS chlorobenzene results were within the quality control limits as were the %RPDs for these two compounds. On this basis no action was taken.

Semi-Volatiles - SVOC

The following compounds were detected in the laboratory method blanks for the associated soil samples in SDG Gulfport-012:

<u>Compound</u>	<u>Maximum Concentration</u>	<u>Blank Action Level</u>
Bis(2-ethylhexyl)phthalate ⁽¹⁾	60 µg/kg	600 µg/kg
Bis(2-ethylhexyl)phthalate ⁽²⁾	50 µg/kg	500 µg/kg

To: R. Fisher
Page: 3

(1) Maximum concentration present in the laboratory method preparation blank SBLK1003BS1 affecting SDG samples 01SS01701, 01SS042001, 01SS01401, 01SS01401DUP, 01SS01501, 01SS02401, 01SS02501, 01SS13701, 01SS13801, 01SS13901, and 01SS13901DUP.

(2) Maximum concentration present in the laboratory method preparation blank SBLK1007BS1 affecting SDG samples 01SBDIT01, 01SBDIT02, and 01SBDIT03.

An action level of 10X the maximum contaminant concentration for the common laboratory contaminant phthalates was established to evaluate laboratory contamination. Dilution factors, sample aliquots, and % solids were taken into consideration during the application of all action levels. The positive results for bis(2-ethylhexyl)phthalate below the blank action level were qualified as non-detected, (U).

The calibration verification %D was greater than the 25% quality control limit for bis(2-ethylhexyl)phthalate, butylbenzylphthalate, caprolactam, and 2,4-dimethylphenol for instrument BNA1 on 10/07/08 @ 09:08. The affected SDG samples 01SS01701, 01SS042001, 01SS01401, 01SS01401DUP, 01SS01501, 01SS02401, 01SS02501, 01SS13701, 01SS13801, 01SS13901, and 01SS13901DUP non-detected results for butylbenzylphthalate, caprolactam, and 2,4-dimethylphenol were qualified estimated, (UJ). The associated sample bis(2-ethylhexyl)phthalate results were previously qualified as non-detected, (U), due to blank contamination so no further action was necessary.

The calibration verification %D was greater than the 25% quality control limit for bis(2-ethylhexyl)phthalate and butylbenzylphthalate for instrument BNA1 on 10/08/08 @ 10:01. The affected SDG samples 01SBDIT01, 01SBDIT02, and 01SBDIT03 non-detected results for butylbenzylphthalate were qualified estimated, (UJ). The associated sample bis(2-ethylhexyl)phthalate results were previously qualified as non-detected, (U), due to blank contamination so no further action was necessary.

The matrix spike duplicate (MSD) performed on sample 01SS02501 had a % recovery greater than the quality control limit for di-n-octylphthalate. The sample di-n-octylphthalate MS result was within the QC limits and the % RPD for the MS/MSD was within the QC limits. Therefore, no data qualification was necessary for the associated sample non-detected di-n-octylphthalate result.

The MS/MSD performed on sample 01SS02501 had a % RPD greater than the quality control limit for hexachlorocyclopentadiene. The associated sample non-detected result for hexachlorocyclopentadiene was not qualified as both the MS and MSD % recoveries were within the quality control limits.

Pesticides/PCBs

The higher PEST result from either GC column is generally reported but due to matrix interferences (caused by a significant PCB concentration for one sample), some PEST results were reported from the GC column which had the lesser PCB interference regardless if the concentration was lower.

The continuing calibration average %Ds for 4,4'-DDT, methoxychlor, and endrin ketone were greater than 15% the quality control limit for the primary GC column MR-1 on instrument ECD3 on 10/10/08 @ 15:59 affecting all SDG primary GC column PEST sample results. The continuing calibration average %D for 4,4'-DDT was greater than 15% the quality control limit for the secondary GC column MR-2 on instrument ECD3 on 10/10/08 @ 15:59 affecting all SDG secondary GC column PEST sample results. All positive and non-detected SDG sample results for 4,4'-DDT were qualified estimated, (J) and (UJ), respectively. The SDG non-detected sample results for methoxychlor and endrin ketone were not qualified since the secondary GC column continuing calibration %Ds were within the quality control limits. The positive methoxychlor result for sample 01SS01701 was qualified estimated, (J), as it was reported from the primary GC column. The positive endrin ketone result for sample 01SBDIT02 was more severely qualified due to %D primary and secondary GC column difference and no further action was necessary.

The continuing calibration average %Ds for 4,4'-DDE, 4,4'-DDT, methoxychlor, and endrin ketone were greater than 15% the quality control limit for the primary GC column MR-1 on instrument ECD3 on 10/10/08 @ 19:22 affecting SDG primary GC column PEST sample results for samples 01SS13701, 01SS13801, 01SS13901, 01SS13901DUP, 01SBDIT01, 01SBDIT02, and 01SBDIT03. The continuing calibration average %D for 4,4'-DDT and methoxychlor was greater than 15% the quality control limit for the secondary GC column MR-2 on instrument ECD3 on 10/10/08 @ 19:22 affecting SDG secondary GC column PEST sample results for the aforementioned samples. All positive and non-detected SDG sample results for 4,4'-DDT and methoxychlor were qualified estimated, (J) and (UJ), respectively, for affected samples 01SS13701, 01SS13801, 01SS13901, 01SS13901DUP, 01SBDIT01, 01SBDIT02, and 01SBDIT03. No 4,4'-DDE and endrin ketone associated sample results were qualified since the within the QC limit secondary GC column results were reported.

The PEST surrogate % recovery for tetrachloro-m-xylene (TCMX) for both the primary and secondary GC columns exceeded the quality control limits for sample 01SBDIT02. Non-detected PEST sample results were not qualified. Positive PEST sample results were qualified estimated, (J), except where more severely qualified due to other issues.

The PEST MS/MSD % recovery and the %RPD was greater than the quality control limit for dieldrin for sample 01SS02501. The positive sample result for dieldrin was qualified estimated, (J). No other sample was qualified due to this issue as it appears to be a matrix effect confined to this sample.

The PEST/PCB %D between the primary and secondary GC columns exceeded 25% for the analytes as listed below. Associated sample positive detections for single component compounds >100% D were qualified rejected, (R), and detects >25% and <100% D were qualified estimated, (J). The higher result of the two GC columns was used in the final report except as where noted.

<u>Sample</u>	<u>Analyte</u>	<u>%D</u>	<u>Qualification</u>
01SBDIT01	Beta-BHC	90.8	J*

	Gamma-chlordane	99.6	J*
	Methoxychlor	76.4	J*

*Lower result used due to matrix interference.

Herbicides

The continuing calibration %D was greater than the 15% quality control limit for a variety of herbicides on the secondary GC column RTX-CLP2 for instrument ECD2 on 10/09/08 @ 23:36, 10/10/08 @ 08:01, @ 10:38, and @ 18:59. No action was taken since the primary GC column RTX-CLP had %Ds within the quality control limits and all SDG samples had non-detected results for herbicides 2,4,5-T, 2,4,5-TP(SILVEX), and 2,4-D.

The HERB % recovery was greater than the quality control limit for the surrogate DCAA for soil samples 01SS13801, 01SS13901, 01SS13901DUP, 01SBDIT01, 01SBDIT02, and 01SBDIT03 as well as the MS/MSD for sample 01SS02501 on the secondary GC column RTX-CLP2 for instrument ECD2. These quality control exceedances were attributed to matrix effects caused by the soil samples. No action was taken due to these QC limit exceedances since the primary GC column RTX-CLP had satisfactory quality control surrogate DCAA performance and all herbicides sample results were non-detected.

The HERB MS % recovery was greater than the quality control limits for 2,4-D, 2,4,5-TP(SILVEX), and 2,4,5-T for the secondary HERB GC column and the HERB MSD % recovery was greater than the quality control limit for 2,4,5-TP(SILVEX) for the secondary GC column. No action was taken for these QC limit

To: R. Fisher
Page: 6

exceedances since the sample had all non-detected herbicide results and the primary GC column appeared to have satisfactory QC limit % recoveries.

Notes

Positive results reported below the quantitation limit but above the method detection limit were qualified as estimated, J.

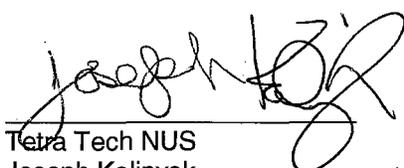

Executive Summary

Laboratory Performance: Methylene chloride, toluene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene and acetone were detected in the VOC laboratory method blank. Continuing calibration %Ds affected sample data qualifications in the VOC fraction. Bis(2-ethylhexyl)phthalate was detected in the SVOC laboratory method blank. Continuing calibration %Ds exceeded the QC limits in the SVOC fraction. Some PEST results had matrix interferences which resulted in the alternate GC column sample data being reported. The pesticide fraction had continuing calibration %Ds which exceeded the quality control limits. There was a PEST surrogate recovery problem with one sample. There was a PEST MS/MSD % recovery QC limit exceedance resulting in data qualification. There were PEST % differences between GC column results which exceeded the quality control limits for a number of samples.

Other Factors Affecting Data Quality: None.

The data for these analyses were reviewed with reference to the EPA Functional Guidelines for Organic Data Validation (October 1999) and the Department of Defense (DoD) document entitled "Quality Systems Manual (QSM) for Environmental Laboratories" (January 2006). The text of this report has been formulated to address only those problem areas affecting data quality.

"I attest that the data referenced herein were validated according to the agreed upon validation criteria as specified in the DoD Guidelines."

APPENDIX A

QUALIFIED ANALYTICAL RESULTS

Data Validation Qualifier Codes:

- A = Lab Blank Contamination
- B = Field Blank Contamination
- C = Calibration Noncompliance (e.g. % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
- C01 = GC/MS Tuning Noncompliance
- D = MS/MSD Recovery Noncompliance
- E = LCS/LCSD Recovery Noncompliance
- F = Lab Duplicate Imprecision
- G = Field Duplicate Imprecision
- H = Holding Time Exceedance
- I = ICP Serial Dilution Noncompliance
- J = GFAA PDS - GFAA MSA's $r < 0.995$
- K = ICP Interference - includes ICS % R Noncompliance
- L = Instrument Calibration Range Exceedance
- M = Sample Preservation Noncompliance
- N = Internal Standard Noncompliance
- N01 = Internal Standard Recovery Noncompliance Dioxins
- N02 = Recovery Standard Noncompliance Dioxins
- N03 = Clean-up Standard Noncompliance Dioxins
- O = Poor Instrument Performance (e.g. base-line drifting)
- P = Uncertainty near detection limit ($< 2 \times$ IDL for inorganics and $<$ CRQL for organics)
- Q = Other problems (can encompass a number of issues; e.g. chromatography, interferences, etc.)
- R = Surrogates Recovery Noncompliance
- S = Pesticide/PCB Resolution
- T = % Breakdown Noncompliance for DDT and Endrin
- U = % Difference between columns/detectors $>25\%$ for positive results determined via GC/HPLC
- V = Non-linear calibrations; correlation coefficient $r < 0.995$
- W = EMPC result
- X = Signal to noise response drop
- Y = Percent solids $<30\%$
- Z = Uncertainty at 2 sigma deviation is greater than sample activity

Volatiles

Method: The samples were extracted/analyzed by USEPA SW-846 Methods 5035/8260B (EnCore field sampling with lab preservation followed by purge and trap then capillary column GC/MS) for soils upon receipt to the laboratory in satisfactory condition.

Comments: The volatile analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following note/exceptions:

- The method blanks associated with these samples have reported concentrations of acetone, methylene chloride, 1,2,3-trichlorobenzene and/or 1,2,4-trichlorobenzene. Reported concentrations in the associated samples are qualified with a "B".
- In spike samples V4BLK1003LCS/LCSD, recoveries of 1,2-dichloroethane exceeded the limit of 125% at (120%)/138%. All other recoveries and relative percent differences were within limits.
- In spike samples 01SS02501MS/MSD, recoveries of chlorobenzene and 1,2,4-trichlorobenzene were below the respective limits of 74% and 65% at (75%)/74% and 60%/(65%), respectively. All other recoveries and relative percent differences were within limits.
- Manual integrations: Quantitation signals were manually integrated in order to accurately reflect the peak areas based on the technical judgment of the analyst. A listing of the manual integrations performed and reason for the integration is attached to this case narrative. Before and after "pictures" are included with the raw data for each integration performed.

Semivolatiles

Method: The samples were analyzed by USEPA SW-846 Methods 3541/8270C (automated soxhlet extraction followed by capillary column GC/MS) for soils upon receipt to the laboratory in satisfactory condition.

Comments: The analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following exceptions:

- In the initial calibration verification, 3,3'-dichlorobenzidine exceeded 25% difference with a positive bias. It was not detected in the associated samples.
- Bis(2-ethylhexyl)phthalate was detected in the method blanks at a concentration less than 1/2 the quantitation limit. Reported concentrations in the associated samples are qualified with a "B".
- In spike samples 01SS02501MS/MSD, 1 of 66 relative percent differences and 1 of 132 recoveries were outside the established limits. See form 3. Analyses of the MS/MSD were started 12 hours 30 minutes and 13 hours 6 minutes after the associated tuning standard.
- Manual integrations: Quantitation signals were manually integrated in order to accurately reflect the peak areas based on the technical judgment of the analyst. A listing of the manual integrations performed and reason for the integration is attached to this case narrative. Before and after "pictures" are included with the raw data for each integration performed.

Pesticides/PCBs

Method: The samples were analyzed by USEPA SW-846 Methods 3550C/8081A/8082 (sonication extraction followed by capillary column GC/ECD) for soils upon receipt to the laboratory in satisfactory condition.

Comments: The analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following exceptions:

- Initial analyses of the samples were completed using full calibration for 1016/1260. Analysis of sample 01SBDIT02 was completed under full 1242 calibration. As no other aroclor patterns were identified, no other aroclor calibration checks were performed.
- Some analytes in the continuing calibration verifications (CCVs) exceeded the 20%D limit with a positive bias. In most cases, the analyte was not detected above the quantitation limit and surrogate recoveries were determined not to have been biased into control by the exceedences. For the ending calibration verifications analyzed 10/10/08 at 19:22, 4,4'-DDT exceeded 20% difference at -21.3%/-22.4%. Reported concentrations in the associated samples are qualified with a "Y" for a potential negative bias.
- In spike samples 01SS02501MS/MSD, recoveries of dieldrin exceeded the limit of 125% at 1557%/270% with a relative percent difference of 63. This is attributed to fluctuations in the natural sample concentration or "hot spots".
- Recoveries of the surrogate TCMX exceeded the limit of 120% at 137%/136% in sample 01SBDIT02. This is attributed to sample matrix. In addition, the pesticide form I for this

sample is qualified with the statement "The reported concentration for these compounds may be due to the presence of PCB".

- As is necessary for all GC/LC chromatography, manual integrations were performed to correctly quantitate target analytes. A "before" chromatogram and "after" chromatogram is provided for all sample analyses to provide information regarding the manual integrations performed.

Herbicide Samples

Method: The samples were analyzed by USEPA SW-846 Methods 8151A (sonication and separatory funnel extraction then esterification and capillary column GC/ECD) for soils upon receipt to the laboratory in satisfactory condition.

Comments: The analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following exceptions:

- Some analytes in the initial calibration verification (ICV) or continuing calibration verifications (CCVs) exceeded the 20 %D limit with a high bias. No target analytes were detected in the associated samples.
- In spike samples 01SS02501MS/MSD, 4 of 6 recoveries exceeded limits with a positive bias. See form 3.
- As is necessary for all GC/LC chromatography, manual integrations were performed to correctly quantitate target analytes. A "before" chromatogram and "after" chromatogram is provided for all sample analyses to provide information regarding the manual integrations performed.

I certify that, to the best of my knowledge and based upon my inquiry of those individuals immediately responsible for obtaining the information, the data package is in compliance with the terms and conditions of the contract, both technically and for completeness, with the exception of the conditions detailed in the case narrative, as verified by the following signature.

Marcia K. McGinnity
Senior Project Manager

ANALYTICAL REPORT TERMS AND QUALIFIERS (ORGANIC)

- MDL:** The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from analysis of a sample containing the analyte in a given matrix.
- EQL:** The estimated quantitation limit (EQL), also known as the reporting limit (RL), is defined as the estimated concentration above which quantitative results can be obtained with a specific degree of confidence. Empirical Laboratories defines the EQL to be at or near the lowest standard of the calibration curve.
- U:** The presence of a "U" indicates that the analyte was analyzed for but was not detected or the concentration of the analyte quantitated below the MDL.
- B:** The presence of a "B" to the right of an analytical value indicates that this compound was also detected in the method blank and the data should be interpreted with caution. One should consider the possibility that the correct sample result might be less than the reported result and, perhaps, zero.
- D:** When a sample (or sample extract) is rerun diluted because one of the compound concentrations exceeded the highest concentration range for the standard curve, all of the values obtained in the dilution run will be flagged with a "D".
- E:** The concentration for any compound found which exceeds the highest concentration level on the standard curve for that compound will be flagged with an "E". Usually the sample will be rerun at a dilution to quantitate the flagged compound.
- J:** The presence of a "J" to the right of an analytical result indicates that the reported result is estimated. The mass spectral data pass the identification criteria showing that the compound is present, but the calculated result is less than the EQL. One should feel confident that the result is greater than zero and less than the EQL.
- P:** The associated numerical value is an estimated quantity. There is greater than a 40% difference between the two GC columns for the detected concentrations. The higher of the two values is reported.
- M:** The presence of an "M" to the right of an analytical result indicates that the sample matrix interfered with the quantitation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.
- I:** The presence of an "I" to the right of an analytical result that the presence of a qualitative interference could have caused a false positive or over estimation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.

Chromatographic Flags for Manual Integrations

- A:** The peak was manually integrated as it was **not integrated** in the original chromatogram.
- B:** The peak was manually integrated due to **resolution or coelution** issues in the original chromatogram.
- C:** The peak was manually integrated to **correct the baseline** from the original chromatogram.
- D:** The peak was manually integrated to **identify the correct peak** as the incorrect peak was identified in the original chromatogram.
- E:** The peak was manually integrated to **include the entire peak** as the original chromatogram only integrated part of the peak.

VOC 4-methyl-2-pentanone Sample 015501501

$$\frac{4929}{514093} \times \frac{308 \times 5}{(0.239)(0.898)(5.6)} \approx 1.196 \mu\text{g}/\text{kg}$$

SVOC di-ethylphthalate Sample 015501501

$$\frac{65294}{2319808} \times \frac{40 \times 1000 \times 0.5}{(1.399)(0.898)(15)(0.5)} \approx 59.7 \mu\text{g}/\text{kg}$$

PCB Aroclor-1242 7 Sample 015B01102

Peak #1 $\left(\frac{105841}{968} \right) \times \frac{5 \times 5 \times 2}{(15)(2)(.881)} \approx 2274 \mu\text{g}/\text{kg}$

#2 $\left(\frac{200382}{385} \right) \times \text{"} \approx 1083 \mu\text{g}/\text{kg}$

#3 $\left(\frac{539716}{303} \right) \times \text{"} \approx 3706 \mu\text{g}/\text{kg}$

#4 $\left(\frac{619559}{496} \right) \times \text{"} \approx 2599 \mu\text{g}/\text{kg}$

#5 $\left(\frac{68980}{614} \right) \times \text{"} \approx 2338 \mu\text{g}/\text{kg}$

#6 $\left(\frac{347163}{\text{Not calcd}} \right) \times \text{"} \approx$

$$2274 + 1083 + 3706 + 2599 + 2338 \approx 2400 \mu\text{g}/\text{kg}$$

Laboratory Method/Preparation Blank Results

The following contaminants were detected in the laboratory method/preparation blanks at the following maximum concentrations:

<u>Analyte</u>	<u>Maximum Concentration</u>	<u>Action Level</u>
Lead ⁽¹⁾	1.90 µg/L	9.50 µg/L

⁽¹⁾ Affects all groundwater samples and 01RB090908.

An action level of 5X the maximum concentration was used to evaluate the sample data for blank contamination. Sample aliquot, percent solids, and dilution factors, if applicable, were taken into consideration when evaluating for blank contamination. Lead was qualified due to laboratory blank contamination.

Matrix Spike Recoveries

The matrix spike (MS) and matrix spike duplicate (MSD) percent recoveries (%Rs) for antimony were less than the respective lower quality control limits for the MS and MSD analyses of sample 01SS0701 affecting all soil samples. The positive and non-detected results reported for antimony were qualified as estimated, "J" and "UJ", respectively.

Notes

The rinsate blank was not used to establish blank action levels and was not qualified due to laboratory blank contamination.

The third continuing calibration verification analyzed on 09/30/08 at 20:48 yielded a %R for calcium greater than the upper quality control limit (110%) affecting sample 01RB091108. No data was qualified because calcium was reported as non-detected in sample 01RB091108.

The laboratory did not qualify non-detected cyanide results with a "U" qualifier on Form 1 reports. The Form 1 reports were corrected manually by the data validator.

Originally, the electronic data deliverable (EDD) from the laboratory did not include "U" qualifiers for non-detected cyanide results. A revised EDD was emailed to the data validator and a database specialist uploaded it thereby correcting the database.

The instrumental raw data for cyanide is expressed in units of mg/L. The data validator attempted to perform a sample result verification using those units and obtained a different final result for cyanide than the laboratory reported. The laboratory was contacted and a representative explained that the instrumental raw data units expressed as mg/L are incorrect and actually should be mg/kg. Sample result verifications for cyanide agree with the reported laboratory results when raw data units expressed as mg/kg are used in sample result verification calculations.

Executive Summary

Laboratory Performance: Lead was qualified due to laboratory blank contamination.

Other Factors Affecting Data Quality: Antimony was qualified due to matrix spike noncompliance.

TO: FISHER, R – PAGE 3
DATE: NOVEMBER 11, 2008

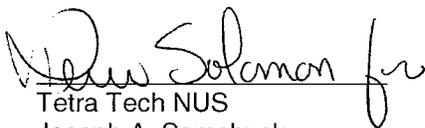

The data for these analyses were reviewed with reference to the "National Functional Guidelines for Inorganic Review", October 2004 and the Department of Defense (DoD) document entitled "Quality Systems Manual (QSM) for Environmental Laboratories" (January 2006).

The text of this report has been formulated to address only those problem areas affecting data quality.

"I attest that the data referenced herein were validated according to the agreed upon validation criteria as specified in the DoD QSM and the Quality Assurance Project Plan (QAPP)."

APPENDIX A

QUALIFIED ANALYTICAL RESULTS

Data Validation Qualifier Codes:

- A = Lab Blank Contamination
- B = Field Blank Contamination
- C = Calibration Noncompliance (e.g. %RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
- C01 = GC/MS Tuning Noncompliance
- D = MS/MSD Recovery Noncompliance
- E = LCS/LCSD Recovery Noncompliance
- F = Laboratory Duplicate Imprecision
- G = Field Duplicate Imprecision
- H = Holding Time Exceedance
- I = ICP Serial Dilution Noncompliance
- J = GFAA PDS – GFAA MSA's $r < 0.995$ / ICP PDS Recovery Noncompliance
- K = IPC Interference – included ICS %R Noncompliance
- L = Instrument Calibration Range Exceedance
- M = Sample Preservation Noncompliance
- N = Internal Standard Noncompliance
- N01 = Internal Standard Recovery Noncompliance Dioxins
- N02 = Recovery Standard Noncompliance Dioxins
- N03 = Clean-up Standard Noncompliance Dioxins
- O = Poor Instrument Performance (e.g. base-line drifting)
- P = Uncertainty near detection limit ($< 2 \times$ IDL for inorganics and $<$ CRDL for organics)
- Q = Other problems (can encompass a number of issues; e.g. chromatography, interferences, etc.)
- R = Surrogate Recovery Noncompliance
- S = Pesticide/PCB Resolution
- T = % Breakdown Noncompliance for DDT and Endrin
- U = % Difference between columns/detectors $> 25\%$ for positive results determined via GC/HPLC
- V = Non-linear calibrations; correlation coefficient $r < 0.995$
- W = EMPC result
- X = Signal to noise response drop
- Y = Percent solids $< 30\%$
- Z = Uncertainty at 2 sigma deviation is greater than sample activity

0809127-08	01SS1201

I certify that, based upon my inquiry of those individuals immediately responsible for obtaining the information and to the best of my knowledge, the data package is in compliance with the terms and conditions of the contract, both technically and for completeness, with the exception of the conditions detailed in the case narrative, as verified by the following signature.

Betty DeVille
Inorganic Lab Manager

I. RECEIPT

No exceptions were encountered unless a Sample Receipt Exception Report is attached to the Chain-of-Custody included with this data package.

I. HOLDING TIMES

- A. **Sample Preparation:** All holding times were met.
- B. **Sample Analysis:** All holding times were met.

II. METHODS

US EPA SW846 Method 3050B was used to digest and method 6010B was used for analysis of ICAP metals. Method 7471A was used to digest and analyze mercury and method 9012A was used to distill and analyze cyanide. Note: The "U" flag indicates that the sample concentration is reported down to the laboratory MDL. The "J" flag indicates that the analyte result is between the

Work Order # 0809091, 0809127
September, 2008

laboratory reporting limit and the laboratory MDL. All methods performed according to EPA guidelines and Empirical Laboratories Standard Operating Procedures.

III. PREPARATION

All methods performed according to EPA guidelines and Empirical Laboratories Standard Operating Procedures.

IV. ANALYSIS

- A. Calibration:** All calibration criteria were met with the following exception: The initial calibration verification for mercury on the second mercury analysis was out of the specification limits of 90 to 110% for mercury at 116.0%.
- The third CCV in the fourth ICAP analysis was out of the specification limits of 90 to 110% for calcium at 115%. The sample impacted by this CCV had a concentration less than the MDL for calcium. There is no impact to the sample data.
- The low level distilled check standard for cyanide was out of the specification limits of 85 to 115% at 80.5% on the first cyanide analysis and at 53.4% on the second cyanide analysis.
- B. Blanks:** All blank criteria were met with the following exceptions: The third CCB in the first ICAP analysis was out of the specification limits for lead at 1.9 ug/L. All impacted samples had concentrations less than the MDL for lead or the sample was reanalyzed. There is no impact to the sample data.
- C. Spikes:** All matrix spikes quality control criteria were met with the following exceptions: The matrix spike and the matrix spike duplicate were out of the specification limits for antimony at 39.7 and 40.2% on sample 01SS0701. The post digestion spike recovery was at 954%. **All associated data are flagged with an "N" on the final report.**
- D. Duplicates:** All duplicate quality control criteria were met.
- E. Samples:** All sample analysis proceeded normally with the following exception: The MDL was increased due to a negative bias on some samples for thallium. The samples impacted are noted in the comment section of the form one.
- F. Laboratory Control Samples:** All percent recovery quality control criteria were met.

Attachments: GULFPORT-011rev20081111(MISC).TXT

Matt - I'm sorry for the delay in responding - we had a quarterly meeting yesterday. Attached is the revised EDD file for Cyanide results. The "U" qualifiers were missing for all the non-detect cyanide results. As for the calculation - what is not clear from the worksheet is that the soil worksheet value is in mg/kg assuming a 1g sample aliquot. This correction factor is reflected on the worksheet under the column MDF (Manual Dilution Factor). The only thing required to finalize the concentration is correcting for the actual extracted sample weight and the percent moisture. Therefore, the calculation for the example given would be:

$(0.03285\text{mg/kg} \cdot 1\text{g}) / (1.03\text{g} \cdot 0.76) = 0.042\text{mg/kg}$ or 0.16mg/kg U .

I apologize for the difficulties encountered with the cyanide data. I have been assured that the worksheet labeling will be clarified for the soils. Please let me know if there is anything else we can provide.

PLEASE NOTE: Our laboratory will be closed on Thursday, November 27th and Friday November 28th for the Thanksgiving Holiday.

Thanks,
Marcia

Hi Marcia,

I performed a sample result verification for CN using raw data and calculated a different result than your laboratory. Please see the attached documents and contact me ASAP to resolve this issue. Thank you for your time and I hope you have a great weekend.

Overview

The sample set for CTO 0065, NCBC Gulfport, SDG Gulfport-011, consists of two (2) trip blanks, two (2) rinsate blanks, six (6) aqueous environmental samples and six (6) soil environmental samples. There were no field duplicates included in this sample delivery group.

All samples were analyzed for volatile organic compounds (VOC), semi-volatile organic compounds (SVOC), organochloride pesticides (PEST), polychlorinated biphenyls (PCB), and herbicides (HERB). The trip blanks were analyzed for VOCs only. The samples were collected by Tetra Tech NUS on September 9 and September 11, 2008 and analyzed by Empirical Laboratories, LLC. All analyses were conducted in accordance with Naval Facilities Engineering Service Center (NFESC) Quality Assurance/Quality Control (QA/QC) criteria using USEPA SW-846 Methods 8260B, 8270C, 8081A, 8082 and 8151B analysis and reporting protocols. The data contained in this SDG were validated with regard to the following parameters:

- * ● Data completeness
- Hold times
- * ● GC/MS Tuning
- Initial/continuing calibrations
- Laboratory method blank results
- Surrogate Recoveries
- Blank Spike/Blank Spike Duplicate Results
- Matrix Spike/Matrix Spike Duplicate Results
- * ● Internal Standards
- * ● Compound Quantitation
- * ● Compound Identification
- * ● Detection Limits

To: R. Fisher
Page: 2

The symbol (*) indicates that quality control criteria were met for this parameter. Problems affecting data quality are discussed below; documentation supporting these findings is presented in Appendix C. Qualified Analytical results are presented in Appendix A. Results as reported by the laboratory are presented in Appendix B.

Volatiles - VOC

The following compounds were detected in the method blanks and rinsate blanks with the associated samples in SDG Gulfport-011:

<u>Compound</u>	<u>Maximum Concentration</u>	<u>Blank Action Level</u>
Methylene chloride ⁽¹⁾	1.00 µg/kg	10.0 µg/kg
Acetone ⁽²⁾	3.1 µg/l (µg/kg)	31.0 µg/l (µg/kg)
Methylene chloride ⁽³⁾	0.30 µg/l	10.0 µg/l

⁽¹⁾ Maximum concentration present in the laboratory method blank affecting soil samples.

⁽²⁾ Maximum concentration present in the rinsate blank 01RB091108 affecting all SDG samples.

⁽³⁾ Maximum concentration present in the laboratory method blank affecting the aqueous samples.

An action level of 10X the maximum contaminant concentration for acetone and methylene chloride was established to evaluate laboratory contamination. Dilution factors and sample aliquots and percent solids for soils, if applicable, were taken into consideration during the application of all action levels. The positive results for acetone and methylene chloride below the blank action level were qualified as non-detected, (U). The concentrations listed in parentheses were for soil samples.

The continuing calibration %D was greater than 25% the quality control limit for 1,2,4-trichlorobenzene for instrument VOA1 on 09/15/08 @ 09:38 affecting samples 01SS0701, 01SS0801, 01SS0901, 01SS1001, 01SS1101, and 01SS1201. The non-detected results reported for 1,2,4-trichlorobenzene for the associated samples were qualified as estimated, (UJ).

The continuing calibration %D was greater than 25% the quality control limit for carbon disulfide for instrument VOA3 on 09/12/08 @ 10:21 affecting samples 01GW2201, 01GW2301, 01GW2401, 01GW2501, 01GW2601, 01GW2701, 01RB090908, and TB090908. The non-detected results reported for carbon disulfide for the associated samples were qualified as estimated, (UJ).

The continuing calibration %D was greater than 25% the quality control limit for bromoform, carbon disulfide, and methyl acetate for instrument VOA3 on 09/15/08 @ 09:53 affecting samples 01TB091108 and 01RB091108. The non-detected results reported for bromoform, carbon disulfide, and methyl acetate for the associated samples were qualified as estimated, (UJ).

A laboratory control sample (LCS) / laboratory control sample duplicate (LCSD) and the matrix spike (MS) / matrix spike duplicate (MSD) for sample 01GW2201 had % RPDs above the QC limits for bromomethane. No action was taken because the LCS/LCSD and MS/MSD % recoveries for bromomethane were within the quality control limits and all samples results were non-detected for bromomethane.

The MS/MSD associated with sample 01SS0701 had % recoveries below the quality control limit for a number of compounds for both the MS and the MSD. The laboratory narrative suggests the problem was due to sample matrix interference. On this basis sample 01SS0701 data was qualified for those compounds for which both the MS and MSD % recovery QC limit non-compliances were less than the quality control limit. Positive and non-detected results for benzene, bromochloromethane, chlorobenzene, dibromochloromethane, 1,2-dibromoethane, cis-1,2-dichloroethene, trans-1,2-dichloroethene, cis-1,3-

To: R. Fisher
Page: 3

dichloropropene, trans-1,3-dichloropropene, ethylbenzene, isopropylbenzene, methyl cyclohexane, styrene, tetrachloroethene, 1,2,3-trichlorobenzene, 1,2,4-trichlorobenzene, trichloroethene, and total xylene for sample 01SS0701 were qualified estimated, (J) and (UJ), respectively.

Semi-Volatiles - SVOC

The following compounds were detected in the method blanks with the associated soil samples in SDG Gulfport-011:

<u>Compound</u>	<u>Maximum Concentration</u>	<u>Blank Action Level</u>
Bis(2-ethylhexyl)phthalate ⁽¹⁾	130 µg/kg	1300 µg/kg
Di-n-butylphthalate ⁽¹⁾	49.0 µg/kg	490 µg/kg

⁽¹⁾ Maximum concentration present in the laboratory method preparation blank SBLK0923BS1 affecting SDG samples 01SS0701, 01SS0801, 01SS0901, 01SS1001, 01SS1101, and 01SS1201.

An action level of 10X the maximum contaminant concentration for the common laboratory contaminant phthalates was established to evaluate laboratory contamination. Dilution factors, sample aliquots, and % solids were taken into consideration during the application of all action levels. The positive results for Di-n-butylphthalate and bis(2-ethylhexyl)phthalate below the blank action level were qualified as non-detected, (U).

The calibration verification %D was greater than the 25% quality control limit for benzaldehyde and bis(2-chloroethyl)ether and the RRF was <0.05 the quality control limit for atrazine for instrument BNA1 on 09/18/08 @ 08:30. The affected samples 01GW2201, 01GW2301, 01GW2401, 01GW2501, 01GW2601, 01GW2701, 01RB090908, and 01RB091108 had non-detected results for benzaldehyde and bis(2-chloroethyl)ether which were qualified estimated, (UJ). The aforementioned samples had non-detected results for atrazine which were qualified rejected, (UR).

The calibration verification %D was greater than the 25% quality control limit for bis(2-chloroethyl)ether and hexachlorocyclopentadiene for instrument BNA1 on 09/24/08 @ 10:43. The affected samples 01SS0901, 01SS1001, 01SS1101, and 01SS1201 had non-detected results for bis(2-chloroethyl)ether and hexachlorocyclopentadiene which were qualified estimated, (UJ).

The laboratory control sample (LCS) SBLK0915BW1 had a % recovery less than the quality control limit for caprolactam. Non-detected results for the associated samples 01GW2201, 01GW2301, 01GW2401, 01GW2501, 01GW2601, 01GW2701, 01RB090908, and 01RB091108 were qualified estimated, (UJ).

The laboratory control sample (LCS) SBLK0923BS1 had a % recovery greater than the quality control limit for caprolactam. Positive results for the associated samples 01SS0901, 01SS1101, and 01SS1201 were qualified estimated, (J). Non-detected results for the associated samples 01SS0701, 01SS0801, and 01SS1001 were not qualified.

The matrix spike (MS) and matrix spike duplicate (MSD) performed on sample 01GW2201 had a % recovery less than the quality control limit for caprolactam. The sample caprolactam non-detected result was qualified estimated, (UJ).

The MS/MSD performed on sample 01GW2201 had a % RPD greater than the quality control limit for 4-nitrophenol. The associated sample non-detected result for 4-nitrophenol was not qualified as both the MS and MSD % recoveries were within the quality control limits for 4-nitrophenol.

The matrix spike duplicate (MSD) performed on sample 01SS0701 had a % recovery less than the quality control limit for acetophenone. The MSD %RPDs were less than the quality control limit for acetophenone

To: R. Fisher
Page: 4

and benzaldehyde. No action was taken on this basis because the MS for the sample had a % recovery within the quality control limit for acetophenone and both the MS and MSD for the sample had % recoveries within the quality control limit for benzaldehyde.

Pesticides/PCBs

The soil samples 01SS0701, 01SS0801, 01SS0901, 01SS1001, 01SS1101, and 01SS1201 were extracted 22 days after date sampled exceeding the quality control limit of 14 days due to the laboratory not logging in samples upon receipt. All associated samples positive results and non-detected results for pesticides and PCBs were qualified estimated, (J) and (UJ), respectively.

The continuing calibration average %D for PCB-1016 was greater than 20% the quality control limit for the secondary GC column MR-2 on instrument ECD3 on 09/29/08 @ 23:20 and 09/30/08 @ 03:38. No action was necessary since the primary GC column MR-1 had a within the quality control limit %D and all samples had non-detected aroclor/PCB results.

The continuing calibration %D was greater than 15% the quality control limit for methoxychlor for the primary GC column MR-1 on instrument ECD3 on 09/30/08 @ 03:20. The continuing calibration %D was greater than 15% the quality control limit for 4,4'-DDD and endrin aldehyde for the secondary GC column MR-2 on instrument ECD3 on 09/29/08 @ 18:45. The continuing calibration %D was greater than 15% the quality control limit for alpha-BHC for the primary GC column MR-1 on 10/07/08 @ 20:58 and on 10/08/08 @ 01:33 on instrument ECD3. The alternate GC column in each case had within the QC limit %Ds so no data qualification was necessary for the affected samples 01GW2201, 01GW2301, 01GW2401, 01GW2501, 01GW2601, 01GW2701, 01RB090908, and 01RB091108.

The continuing calibration %D was greater than 15% the quality control limit for 4,4'-DDT for the primary GC column MR-1 on instrument ECD3 on 10/08/08 @ 01:33 and the secondary GC column MR-2 on instrument on 10/08/08 @ 01:33 affecting samples 01GW2201, 01GW2301, 01GW2401, 01GW2501, 01GW2601, 01GW2701, 01RB090908, and 01RB091108. The positive and non-detected results for the aforementioned samples were qualified estimated, (J) and (UJ), respectively.

The MSD performed on sample 01SS0701 had a % recovery greater than the quality control limit for alpha-BHC. No corrective action was necessary since the MS and the %RPD were within the quality control limits.

The PEST %D between the primary and secondary GC columns exceeded 100% for the analytes as listed below. Associated sample positive detections for single component compounds >100% D were qualified rejected, (R), and detects >25% and <100% D were qualified estimated, (J). The higher result of the two GC columns was used in the final report except as where noted.

<u>Sample</u>	<u>Analyte</u>	<u>%D</u>	<u>Qualification</u>
01GW2401	Beta-BHC	152.4	R*
01GW2601	Beta-BHC	139.8	R*
01RB090908	Beta-BHC	153.3	R*
01RB091108	Aldrin	109.5	R*
	Beta-BHC	96.4	J*
	Delta-BHC	34.8	J
	Gamma-BHC	36.8	J
01SS0701	Alpha-chlordane	36.3	J
01SS0801	Heptachlor epoxide	149.3	R*

To: R. Fisher
Page: 5

01SS1001	4,4'-DDD	145.3	R*
	4,4'-DDE	57.2	J
	4,4'-DDT	81.3	J*
	Endosulfan II	27.5	J
	Endrin aldehyde	36.8	J
	Gamma-chlordane	84.9	J
	Heptachlor epoxide	67.5	J
	Methoxychlor	89.1	J
01SS1101	Endosulfan II	51.0	J
	Heptachlor epoxide	27.1	J

*Lower result used due to matrix interference.

Herbicides

The soil samples 01SS0701, 01SS0801, 01SS0901, 01SS1001, 01SS1101, and 01SS1201 were extracted 22 days after date sampled exceeding the quality control limit of 14 days due to the laboratory not logging in samples upon receipt. All associated samples positive results and non-detected results for herbicides were qualified estimated, (J) and (UJ), respectively.

The initial calibration %RSD was greater than the 15% quality control limit for 2,4-D on the secondary GC column RTX-CLP2 for instrument ECD2 on 09/28/08. No action was taken since the primary GC column RTX-CLP1 had a %RSD within the quality control limits and all associated samples had non-detected results for herbicide 2,4-D.

The initial calibration %RSD was greater than the 15% quality control limit for 2,4-D on the secondary GC column RTX-CLP2 for instrument ECD2 on 10/07/08. No action was taken since the primary GC column RTX-CLP1 had a %RSD within the quality control limits and all associated samples had non-detected results for herbicide 2,4-D.

The % recovery was greater than the quality control limit for the surrogate DCAA for soil samples 01SS0701, 01SS0801, 01SS0901, 01SS1001, 01SS1101, and 01SS1201 on the secondary GC column RTX-CLP2 for instrument ECD2 on 10/07/08. Additionally the surrogate DCAA exceeded the retention time window of +/- 0.03 on the secondary GC column RTX-CLP2 on instrument ECD2 on 10/07/08 for samples 01SS0801, 01SS1101, and 01SS1201. Both of these quality control exceedances were attributed to matrix effects caused by the soil samples. No action was taken for the non-detected results due to these issues since the primary GC column RTX-CLP1 had satisfactory quality control performance. The positive result for 2,4,5-T for sample 01SS0801 was not qualified as the result was reported from the satisfactory primary GC column. The positive results for samples 01SS1001 and 01SS1201 were qualified estimated, (J), as these sample results were reported from the secondary GC column.

Notes

Positive results reported below the quantitation limit but above the method detection limit were qualified as estimated, J.

To: R. Fisher
Page: 6

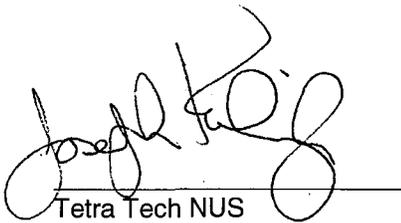

Executive Summary

Laboratory Performance: Methylene chloride and acetone were detected in the VOC field blank. Continuing calibration %Ds affected sample data qualifications in the VOC fraction. Bis(2-ethylhexyl)phthalate and din-n-butylphthalate were detected in the SVOC laboratory method blank. Continuing calibration %Ds exceeded the QC limits in the SVOC fraction. The SVOC fraction had both below and above the quality control limits % recoveries for the LCS and LCSD. The soil samples pesticide and herbicide fractions were extracted 22 days after date sampled exceeding the quality control limit of 14 days due to the laboratory not logging in samples upon receipt. The pesticide fraction had a continuing calibration %D which exceeded the quality control limit and % difference between GC columns which exceeded the quality control limits for a number of samples.

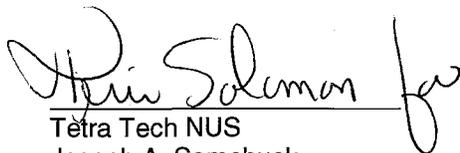

Other Factors Affecting Data Quality: A soil sample VOC had MS/MSD QC limit exceedances which appeared to be due to sample matrix interferences.

The data for these analyses were reviewed with reference to the EPA Functional Guidelines for Organic Data Validation (October 1999) and the Department of Defense (DoD) document entitled "Quality Systems Manual (QSM) for Environmental Laboratories" (January 2006). The text of this report has been formulated to address only those problem areas affecting data quality.

"I attest that the data referenced herein were validated according to the agreed upon validation criteria as specified in the DoD Guidelines."

APPENDIX A

QUALIFIED ANALYTICAL RESULTS

Qualifier Codes:

- A = Lab Blank Contamination
- B = Field Blank Contamination
- C = Calibration Noncompliance (i.e., % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
- C01 = GC/MS Tuning Noncompliance
- D = MS/MSD Recovery Noncompliance
- E = LCS/LCSD Recovery Noncompliance
- F = Lab Duplicate Imprecision
- G = Field Duplicate Imprecision
- H = Holding Time Exceedance
- I = ICP Serial Dilution Noncompliance
- J = GFAA PDS - GFAA MSA's $r < 0.995$
- K = ICP Interference - includes ICS % R Noncompliance
- L = Instrument Calibration Range Exceedance
- M = Sample Preservation Noncompliance
- N = Internal Standard Noncompliance
- N01 = Internal Standard Recovery Noncompliance Dioxins
- N02 = Recovery Standard Noncompliance Dioxins
- N03 = Clean-up Standard Noncompliance Dioxins
- O = Poor Instrument Performance (i.e., base-time drifting)
- P = Uncertainty near detection limit ($< 2 \times \text{IDL}$ for inorganics and $< \text{CRQL}$ for organics)
- Q = Other problems (can encompass a number of issues; i.e. chromatography, interferences, etc.)
- R = Surrogates Recovery Noncompliance
- S = Pesticide/PCB Resolution
- T = % Breakdown Noncompliance for DDT and Endrin
- U = % Difference between columns/detectors $> 25\%$ for positive results determined via GC/HPLC
- V = Non-linear calibrations; correlation coefficient $r < 0.995$
- W = EMPC result
- X = Signal to noise response drop
- Y = Percent solids $< 30\%$
- Z = Uncertainty at 2 sigma deviation is less than sample activity

Volatiles

Method: The samples were extracted/analyzed for the SOW specified analyte lists by USEPA SW-846 Methods 5030B/8260B (purge and trap then capillary column GC/MS) for waters or 5035B/8260B (Encore field sampling followed by laboratory preservation the purge and trap followed by capillary column GC/MS) for solids upon receipt to the laboratory in satisfactory condition.

Comments: The volatile analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following note/exceptions:

- The method blanks associated with these samples had reported concentrations of methylene chloride at concentrations less than 1/2 the quantitation limit. Reported concentrations in the associated samples are qualified with a "B".
- In spike samples V3BLK0915LCS/LCSD, the relative percent difference for bromomethane exceeded the limit of 30 at 44.
- In spike samples 01GW2201MS/MSD, the relative percent difference for bromomethane exceeded the limit of 30 at 32. Analysis of the MSD was started 12 hours 4 minutes after the associated tune standard.
- In spike samples 01SS0701MS/MSD, 39 of 88 recoveries were outside the acceptance limits with all relative percent differences within limits. See form 3. This is attributed to the sample matrix.
- Manual integrations: Quantitation signals were manually integrated in order to accurately reflect the peak areas based on the technical judgment of the analyst. A listing of the manual integrations performed and reason for the integration is attached to this case narrative. Before and after "pictures" are included with the raw data for each integration performed.

I certify that, to the best of my knowledge and based upon my inquiry of those individuals immediately responsible for obtaining the information, the data package is in compliance with the terms and conditions of the contract, both technically and for completeness, with the exception of the conditions detailed in the case narrative, as verified by the following signature.

 Marcia K. McGinnity
 Senior Project Manager

ANALYTICAL REPORT TERMS AND QUALIFIERS (ORGANIC)

- MDL:** The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from analysis of a sample containing the analyte in a given matrix.
- EQL:** The estimated quantitation limit (EQL), also known as the reporting limit (RL), is defined as the estimated concentration above which quantitative results can be obtained with a specific degree of confidence. Empirical Laboratories defines the EQL to be at or near the lowest standard of the calibration curve.
- U:** The presence of a "U" indicates that the analyte was analyzed for but was not detected or the concentration of the analyte quantitated below the MDL.
- B:** The presence of a "B" to the right of an analytical value indicates that this compound was also detected in the method blank and the data should be interpreted with caution. One should consider the possibility that the correct sample result might be less than the reported result and, perhaps, zero.
- D:** When a sample (or sample extract) is rerun diluted because one of the compound concentrations exceeded the highest concentration range for the standard curve, all of the values obtained in the dilution run will be flagged with a "D".
- E:** The concentration for any compound found which exceeds the highest concentration level on the standard curve for that compound will be flagged with an "E". Usually the sample will be rerun at a dilution to quantitate the flagged compound.
- J:** The presence of a "J" to the right of an analytical result indicates that the reported result is estimated. The mass spectral data pass the identification criteria showing that the compound is present, but the calculated result is less than the EQL. One should feel confident that the result is greater than zero and less than the EQL.
- P:** The associated numerical value is an estimated quantity. There is greater than a 40% difference between the two GC columns for the detected concentrations. The higher of the two values is reported.
- M:** The presence of an "M" to the right of an analytical result indicates that the sample matrix interfered with the quantitation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.
- I:** The presence of an "I" to the right of an analytical result that the presence of a qualitative interference could have caused a false positive or over estimation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.

A: The peak was manually integrated as it was not integrated in the original chromatogram.
B: The peak was manually integrated due to resolution or coelution issues in the original chromatogram.
C: The peak was manually integrated to correct baseline from the original chromatogram.
D: The peak was manually integrated to identify the correct peak as the incorrect peak was identified in the original chromatogram.
E: The peak was manually integrated to include entire peak as the original chromatogram only integrated part of the peak.

Semivolatile Samples

Method: The samples were analyzed by USEPA SW-846 Methods 3541/8270C or 3510C/8270C (automated soxhlet or separatory funnel extraction followed by capillary column GC/MS) for soils or waters upon receipt to the laboratory in satisfactory condition.

Comments: The analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following exceptions:

- In the initial calibration verification, 3,3'-dichlorobenzidine exceeded 25% difference with a positive bias. It was not detected in the associated samples.
- Bis(2-ethylhexyl)phthalate and di-n-butylphthalate were detected in method blank SBLK0923BS1. Reported concentrations in the associated samples are qualified with a "B".
- In spike sample SBLK0915BW1LCS, recovery of caprolactam was below the limit of 20% at 19%. All other recoveries were within limits.
- In spike sample SBLK0923BS1LCS, recovery of caprolactam exceeded the limit of 110% at 111%. All other recoveries were within limits.
- In spike samples 01GW2201MS/MSD, 1 of 65 relative percent differences and 2 of 130 recoveries were outside the acceptance limits. See form 3.
- In spike samples 01SS0701MS/MSD, 2 of 66 relative percent differences and 1 of 132 recoveries were outside the acceptance limits. See form 3.
- Manual integrations: Quantitation signals were manually integrated in order to accurately reflect the peak areas based on the technical judgment of the analyst. A listing of the manual integrations performed and reason for the integration is attached to this case narrative. Before and after "pictures" are included with the raw data for each integration performed.

I certify that, to the best of my knowledge and based upon my inquiry of those individuals immediately responsible for obtaining the information, the data package is in compliance with the terms and conditions of the contract, both technically and for completeness, with the exception of the conditions detailed in the case narrative, as verified by the following signature.

Marcia K. McGinnity
Senior Project Manager

ANALYTICAL REPORT TERMS AND QUALIFIERS (ORGANIC)

- MDL:** The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from analysis of a sample containing the analyte in a given matrix.
- EQL:** The estimated quantitation limit (EQL), also known as the reporting limit (RL), is defined as the estimated concentration above which quantitative results can be obtained with a specific degree of confidence. Empirical Laboratories defines the EQL to be at or near the lowest standard of the calibration curve.
- U:** The presence of a "U" indicates that the analyte was analyzed for but was not detected or the concentration of the analyte quantitated below the MDL.
- B:** The presence of a "B" to the right of an analytical value indicates that this compound was also detected in the method blank and the data should be interpreted with caution. One should consider the possibility that the correct sample result might be less than the reported result and, perhaps, zero.
- D:** When a sample (or sample extract) is rerun diluted because one of the compound concentrations exceeded the highest concentration range for the standard curve, all of the values obtained in the dilution run will be flagged with a "D".
- E:** The concentration for any compound found which exceeds the highest concentration level on the standard curve for that compound will be flagged with an "E". Usually the sample will be rerun at a dilution to quantitate the flagged compound.
- J:** The presence of a "J" to the right of an analytical result indicates that the reported result is estimated. The mass spectral data pass the identification criteria showing that the compound is present, but the calculated result is less than the EQL. One should feel confident that the result is greater than zero and less than the EQL.

CHROMATOGRAPHIC FLAGS FOR MANUAL INTEGRATIONS

- A:** The peak was manually integrated as it was not integrated in the original chromatogram.
- B:** The peak was manually integrated due to resolution or coelution issues in the original chromatogram.
- C:** The peak was manually integrated to correct the baseline from the original chromatogram.
- D:** The peak was manually integrated to identify the correct peak as the wrong peak was identified in the original chromatogram.
- E:** The peak was manually integrated to include the entire peak as the original chromatogram only integrated part of the peak.

Pesticides/PCBs

Method: The samples were analyzed by USEPA SW-846 Methods 3541/8081A/8082 (sonication extraction followed by capillary column GC/ECD) for soils or by USEPA SW-846 Methods 3510C/8081A/8082 (separatory funnel extraction followed by capillary column GC/ECD) for waters upon receipt to the laboratory in satisfactory condition.

Comments: The analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following exceptions:

- Samples 01SS0701, 01SS0801, 01SS0901, 01SS1001, 01SS1101 and 01SS1201 were extracted 19 days after date sampled due to samples not being logged in upon receipt. Client was contacted and requested extraction and analysis out of USEPA holding time.
- Analyses of the samples were completed using full calibration for 1016/1260. As no other aroclor patterns were identified, no other aroclor calibration checks were performed.
- PCB-1260 exceeded the 20%D limit with a positive bias in several continuing calibration verifications (CCVs); however, no positive results for 1260 were detected in the samples associated to the CCVs with exceedences.
- In spike samples 01SS0701MS/MSD, alpha-BHC exceeded the limit of 125% at (119%)/126%. All other recoveries and relative percent differences were within limits.
- As is necessary for all GC/LC chromatography, manual integrations were performed to correctly quantitate target analytes. A "before" chromatogram and "after" chromatogram is provided for all sample analyses to provide information regarding the manual integrations performed.

I certify that, to the best of my knowledge and based upon my inquiry of those individuals immediately responsible for obtaining the information, the data package is in compliance with the terms and conditions of the contract, both technically and for completeness, with the exception of the conditions detailed in the case narrative, as verified by the following signature.

Randy D. Ward
Quality Assurance Officer

ANALYTICAL REPORT TERMS AND QUALIFIERS (ORGANIC)

- MDL:** The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from analysis of a sample containing the analyte in a given matrix.
- EQL:** The estimated quantitation limit (EQL), also known as the reporting limit (RL), is defined as the estimated concentration above which quantitative results can be obtained with a specific degree of confidence. Empirical Laboratories defines the EQL to be at or near the lowest standard of the calibration curve.
- U:** The presence of a "U" indicates that the analyte was analyzed for but was not detected or the concentration of the analyte quantitated below the MDL.
- B:** The presence of a "B" to the right of an analytical value indicates that this compound was also detected in the method blank and the data should be interpreted with caution. One should consider the possibility that the correct sample result might be less than the reported result and, perhaps, zero.
- D:** When a sample (or sample extract) is rerun diluted because one of the compound concentrations exceeded the highest concentration range for the standard curve, all of the values obtained in the dilution run will be flagged with a "D".
- E:** The concentration for any compound found which exceeds the highest concentration level on the standard curve for that compound will be flagged with an "E". Usually the sample will be rerun at a dilution to quantitate the flagged compound.
- J:** The presence of a "J" to the right of an analytical result indicates that the reported result is estimated. The mass spectral data pass the identification criteria showing that the compound is present, but the calculated result is less than the EQL. One should feel confident that the result is greater than zero and less than the EQL.
- P:** The associated numerical value is an estimated quantity. There is greater than a 40% difference between the two GC columns for the detected concentrations. The higher of the two values is reported.
- M:** The presence of an "M" to the right of an analytical result indicates that the sample matrix interfered with the quantitation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.
- I:** The presence of an "I" to the right of an analytical result that the presence of a qualitative interference could have caused a false positive or over estimation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.

FORM 8
PESTICIDE ANALYTICAL SEQUENCE

Lab Name: EMPIRICAL LABS Contract: CH2MHILL
 Lab Code: EL Case No.: SAS No.: NA SDG No.: GULFPORT-011
 Column: ZB MR-1 ID: 0.32 (mm) Cont. Calib. Date(s): 09/29/08 - 09/30/08
 Instrument ID: ECD3

THE ANALYTICAL SEQUENCE OF PERFORMANCE BLANKS, AND SAMPLES
GIVEN BELOW:

SURROGATE RT FROM CONTINUING CALIBRATION					
		S1 : 5.09		S2 : 11.47	
CLIENT	LAB	DATE	TIME	S1	S2
SAMPLE NO.	SAMPLE ID	ANALYZED	ANALYZED	RT #	RT #
