EXECUTIVE SUMMARY

This report presents the results of a Site Inspection (SI) at Naval Air Station (NAS) Key West on behalf of the U.S. Navy, Naval Facilities Engineering Command, Southern Division (NAVFACENGCOM-Southern Division). The report covers the inspection of nine sites (Base Realignment and Closure [BRAC] Parcels A, B, C, D, E, F, H, I, and K). The results associated with a tenth parcel (Poinciana Housing) are contained in a separate report (B&R Environmental, 1998b). Tetra Tech NUS (TtNUS) performed this SI in accordance with the SI Workplan for 10 BRAC Properties (Brown and Root Environmental [B&RE], 1998), which was reviewed by the United States Environmental Protection Agency (EPA) and the Florida Department of Environmental Protection (FDEP). These 10 BRAC Parcels were all categorized as "grey" during Environmental Baseline Studies (EBSs). "Grey" Parcel categorization means areas that have not been evaluated or that require additional evaluation before being reclassified into a category eligible for deed transfer.

The goal of this report is to evaluate the data gathered during the SI Field effort and determine the need for any additional investigative or remedial activities prior to reclassification into a category eligible for deed transfer. This report contains a description of each subzone, contaminants detected, a comparison of the detected concentrations with selected screening values, and conclusions and recommendations for each subzone. The subzone conclusions are then summarized to provide overall conclusions and recommendations for the Parcel.

Five soil, one sediment, one surface water, and one groundwater subzone were included in the Hamaca Hawk Missile Site (Parcel A) SI field investigation. Contaminants that may have come from various site and adjacent property uses and activities were considered, including polynuclear aromatic hydrocarbons (PAHs), solvents, battery acid, oils, dielectric fluid from vandalized Army transformers, and metals. Four of the five soil subzones (1, 5, 6, and 7) addressed received a no further action recommendation. Subzone 4, the Sewage Lift Station, is recommended for further action based on multiple detections and one exceedance of arsenic. In addition, further action is recommended for the sediment in the ponds at Parcel A, subzone 9 due to detections of barium, lead, zinc, bis(2-ethylhexyl)phthalate, butyl benzyl phthalate, and 4,4-DDE above screening criteria. Subzones 10 (surface water) and 11 (groundwater) do not require further action.

Parcel B, East Martello Battery contains two subzones that were investigated during the SI. Petroleum, solvents, fuels, and lead from past uses as a defense battery were considered to be potential surface soil contaminants. However, no chemicals were detected in excess of action levels. Subzone 1 (soil) and 3 (groundwater) both received a recommendation of no further action.

Truman Annex DRMO Waste Storage Area (Parcel C) had three soil subzones investigated during the BRAC SI: subzones 1, 3, and 4. All three subzones are recommended for further action. Subzone 1, Building 261 Hazardous Material Storage, indicated exceedances of lead and Aroclor-1260. Subzones 3 and 4, the Former Scrap Metal Storage Areas, were both recommended for further action based on concentrations of benzo(a)pyrene and lead detected above action levels.

Further action is recommended for soil subzone 1 at Truman Annex Seminole Battery (Parcel D). Arsenic, benzo(a)pyrene, and benzo(b)fluoranthene were detected in excess of action levels at the Seminole Battery (subzone 1). All exceedances were detected at the same sample location (SS-03). No chemicals were detected in excess of action levels at the Former Grease Racks (subzone 2). Therefore, no further action is recommended at the Former Grease Racks.

Truman Annex Buildings 102, 103, and 104 (Parcel E) contains six soil subzones, three of which are recommended for further action [Subzones 2 (Former Building 136 soil), 3 (Building 102 and 104 soil), and 9 (Building 103 soil)]. Former Building 136 had arsenic and several semivolatile organic compounds (SVOCs) detected in excess of action levels, and the detected arsenic concentration was indicative of potential carcinogenic human health risks. Subzone 3 exceedances included benzo(a)pyrene and indeno(1,2,3-cd)pyrene. Both SVOC concentrations were indicative of potential carcinogenic risks. Several SVOCs, as well as a polychlorinated biphenyl (PCB), were detected in excess of screening criteria at subzone 9, Building 103 soil. Further action was recommended based on the potential carcinogenic risk associated with these chemicals.

Parcel F, Truman Annex Building 223, contains two soil subzones of interest. Subzone 1 is the Former Lube Area. Due to a single exceedance of arsenic that was indicative of potential carcinogenic human health risks, further action is recommended. Subzone 3 is the Building 223 Equipment Repair Shop. Again, arsenic exceeded its action level. The arsenic concentration at subzone 3 was indicative of both potential carcinogenic and noncarcinogenic human health risks. For this reason, further action is recommended.

Parcel H is Trumbo Point Piers D-1 and D-3. Parcel H groundwater (subzone 6) was the medium of concern. No chemicals were detected in excess of screening criteria. Monitoring well DO6-MW-42 was not sampled at the time the other samples were taken because of the presence of free product in the well. An Interim Remedial Action (IRA) was performed at MW-42 to remove the free product. Samples taken before and after the IRA contain no chemicals in excess of action levels. No further action is recommended at Parcel H, subzone 6.

Parcel K contains three subzones of concern. Soil subzones 1, 2, and 3 were investigated in this SI. Subzone 1, Building 149 Port Operations and Hazardous Waste Storage Area, surface soil was sampled and analyzed for VOCs, SVOCs, and inorganics. No chemicals were detected in excess of their action levels. In addition, no chemicals were detected in excess of action levels in subzone 2 (Remainder Public Works Maintenance Facilities) or 3 (Building 84). All subzones of concern at Parcel K were recommended for no further action.

Truman Annex groundwater was considered as one subzone in the SI. Fuels, oils, metals, and solvents were considered as potential groundwater contaminants at Truman Annex. Nine groundwater screening samples were collected in Parcels D, E, F, and K. These groundwater screening samples were used in determining the location of five permanent wells installed during the SI field effort. One SVOC (phenanthrene) and one VOC (benzene) exceeded their action levels at a single well in Parcel K. Ecological risks from the chemicals were determined to be negligible. There were no other exceedances in groundwater samples at Truman Annex. No further action or investigation is recommended for Truman Annex groundwater except in the vicinity of Buildings 102, 103, and 104 at Parcel E, which is scheduled for additional investigation during the Supplemental SI at Truman Annex.

1.0 INTRODUCTION

Tetra Tech NUS (TtNUS) has performed a Site Inspection (SI) of Base Realignment and Closure (BRAC) Properties at the Naval Air Station (NAS) Key West, Florida on behalf of the U.S. Navy, Naval Facilities Engineering Command, Southern Division (NAVFACENGCOM-Southern Division). This SI Report was completed under Comprehensive Long-Term Environmental Action - Navy (CLEAN) Contract Number N62467-94-D-0888, Contract Task Order 0032.

1.1 PURPOSE AND SCOPE OF REPORT

This SI was conducted under the authority of the BRAC Act of 1992 and was designed to gather information to support a reclassification of Parcels designated as "grey" during the development of the parcels' draft Environmental Baseline Studies (EBSs). These BRAC Parcels were previously referred to as "Zones" in the BRAC SI Workplan (B&R Environmental, 1998a). The grey Parcel categorization is for areas that have not been evaluated or that require additional evaluation. A Parcel cannot be considered for deed transfer until all investigative and, if necessary, remedial actions have been determined. The Parcel can then be reclassified into a category eligible for deed transfer. The goal of this report is to evaluate the data gathered during the SI field effort and determine the need for any additional remedial activities prior to reclassification of the nine BRAC Parcels.

The nine BRAC Parcels addressed in this report are located at:

- Hamaca Hawk Missile Site (Parcel A)
- East Martello Battery (Parcel B)
- Truman Annex (Parcels C, D, E, F, and K)
- Trumbo Point (Parcels H and I)

A tenth Parcel, Poinciana Housing, was addressed in a separate SI report (B&R Environmental, 1998b).

1.2 REPORT ORGANIZATION

This SI report consists of nine major sections and four appendices. Section 1 provides an introduction, the purpose and scope of the report, a facility description, an overview of the base environmental setting, an explanation of the Data Quality Objective (DQO) Process, a synopsis of field procedures, an overview of the data quality assessment process, and a discussion of the data interpretation and presentation

methods employed in this report. Sections 2 through 9 each characterize one of the grey BRAC Parcels mentioned above. The sections provide additional description of individual subzones within each Parcel and present the results of the SI for each subzone. The subsections that discuss the SI findings for each subzone present the contaminants detected and compare the detected concentrations with selected screening values. These subsections are accompanied by maps that place results in a geographic frame of reference. Conclusions are presented for each subzone based on the SI findings in that particular area. The subzone conclusions are then summarized in the last subsection of each Section to provide overall Conclusions and Recommendations for the Parcel.

This report includes four appendices. Appendix A presents the responses to comments on the SI Report submitted by the Florida Department of Environmental Protection (FDEP) and the United States Environmental Protection Agency (EPA). Appendix B provides field documentation including a summary of all amendments to and deviations from the SI Workplan for Ten BRAC Properties, NAS Key West, Florida (B&R Environmental, 1998a); copies of all field data sheets including boring logs, sample collection forms, well development logs, and well completion logs; and survey data. Appendix C provides documentation in support of the estimated risk process as described in Section 1.8.2.2. Appendix D consists of a compact disk, which contains the complete SI data set used in the decision-making process. The data is included in standard database format (BRACSI.dbf) and portable document format (BRACSI.pdf).

1.3 NAS KEY WEST DESCRIPTION

Several installations in various parts of the lower Florida Keys compose NAS Key West. The U.S. Navy manages 6,323 acres of land divided into 20 separate tracts in the lower Florida Keys, concentrated around Key West and Boca Chica Key (Figure 1-1) in southern Monroe County (B&R Environmental, 1998c). Key West, one of the two most western major islands of the Florida Keys, is approximately 150 miles southwest of Miami and 90 miles north of Havana, Cuba. Key West connects to the mainland by the Overseas Highway (U.S. Highway no. 1).

The missions for NAS Key West changed dramatically in 1974, resulting in the relocation of several units. At present, NAS Key West is proceeding with realignment of aviation operations, a research laboratory, communications intelligence, counternarcotics operations, a weather service, and several other activities. In addition to the Naval activities and units, other Department of Defense (DOD) and Federal agencies at NAS Key West include the U.S. Air Force, U.S. Army, and U.S. Coast Guard (USCG).

The nine BRAC Parcels addressed by this report are all located on the island of Key West (Figure 1-2). These Parcels are located in three geographically distinct areas (Truman Annex, Trumbo Point, and Key

West Interior), as discussed below. As part of the DQO Process (see Section 1.6), each BRAC Parcel was broken into a number of subzones based on the physical geographic boundaries and previous uses. The nomenclature used for the subzone indicates the identity of both the Parcel and the subzone (e.g., GRYZNA-SZN1 is the designation for grey Parcel A, subzone 1).

1.3.1 Truman Annex

The Truman Annex BRAC Parcels (Figure 1-2) include:

- Parcel C – Defense Reutilization and Marketing Office (DRMO) Waste Storage Area
- Parcel D – Seminole Battery
- Parcel E – Buildings 102, 103, and 104
- Parcel F – Building 223
- Parcel K – The Waterfront Maintenance Facilities

These five Parcels make up a contiguous piece of land that is part of the Navy's Truman Annex Facility located on the southwest end of Key West. The area is flat terrain that slopes gently to the southwest. Information pertaining to the current and past operations on these Parcels is limited since the EBSs for the Truman Annex Parcels are in draft form.

Truman Annex has a long history as a defense facility. In 1823, after Key West was purchased by an American citizen, the Navy was dispatched to the island to remove pirates inhabiting most of it. The Navy then occupied the northernmost portion of the west end of Key West. The Army acquired land on the western end of Key West in 1845 to build Fort Zachary Taylor, which provided support during the Mexican-American War. Seminole Battery was constructed to carry out defenses during the Civil War. Much of the land consisted of salt ponds, which limited further construction. From 1909 to 1919, the United States conducted landfill operations on the northern portion of the island in the area from the Army pier to the Naval Station.

Gradually, the Navy assumed control of the entire western tip of Key West. As early as 1918, and particularly during the 1940s through the early 1970s, submarines were berthed at eight finger piers in the turning basin. Most of the buildings along the quay were used for support of schools, units, and activities relating to submarines. The majority of the support buildings were demolished after 1982.

1.3.2 **Trumbo Point**

Two BRAC Parcels are located on Trumbo Point on the northwest end of Key West (Figure 1-2). Only one of these Parcels (Parcel H – Piers D-1 and D-3) is addressed in this report. The need for taking environmental samples at Parcel I (Building B-48), which includes the building and surrounding parking areas, was eliminated from the SI during the DQO Process phase of the workplan development, as discussed in Section 1.6.

The area around Trumbo Point is composed of flat terrain that slopes gently to the southeast. Piers D1 and D3 extend out into the Gulf of Mexico. Two of the buildings currently present on the BRAC SI Parcel at Trumbo Point (B-27 and B-28) were originally constructed as ordnance facilities. Buildings B-27 and B-28 were used as shop and maintenance facilities for ordnance.

The City of Key West, the Monroe County School District, and the USCG own tracts of land adjacent to the BRAC Parcels located on Trumbo Point. The tract owned by the City of Key West had a coal-fueled power plant on it that generated power for the surrounding Keys. The tar pits on the property were subsequently remediated by the City of Key West. The City of Key West also was granted an easement for sewer lines through Naval property on Trumbo Point to discharge to the Key West Bight. The lines are no longer used. They are capped and are severely rusted and pitted on the visible portions of discharge piping. The Monroe County School District has a garage, maintenance facility, and administrative complex on its tract of land. Three aboveground storage tanks (ASTs) used for gasoline, diesel fuel, and oil are located on the school district's property. In 1976, ownership of Pier D-2, located on Trumbo Point, was transferred from the Navy to the USCG. The USCG currently holds approximately 13 acres on Trumbo Point. Ship refueling and hazardous waste storage are among the activities at these USCG facilities.

1.3.3 **Key West Interior**

The two Key West Interior BRAC Parcels addressed by this report are made up of two separate land parcels on the eastern end of Key West (Figure 1-2). Both Hamaca Hawk Missile Site (Parcel A) and East Martello Battery (Parcel B) are located off Government Road to the northwest of the Key West International Airport. The two Parcels are separated by a quarter mile and are adjacent to salt ponds with mangrove swamps. Both Parcels are characterized as having flat terrain with a surface-water body located nearby. A portion of each Parcel drains to its respective surface-water body.

A third Key West Interior BRAC Parcel, Poinciana Housing (Parcel G), is not discussed in this report. The Parcel, located on the east end of Key West near the Naval Regional Medical Clinic, was specifically addressed in a separate SI Report (B&R Environmental, 1998b) issued during 1998.

1.4 KEY WEST ENVIRONMENTAL SETTING

The island of Key West is approximately 4 miles long and 1.5 miles wide. The City of Key West is the county seat for Monroe County. The principal industry in Key West is tourism, which draws 1.5 million tourists annually (Roberts, 1998). Tourism, fishing, wholesale and retail trade, services, construction, finance, insurance, real estate, Federal, state and local government, and transportation industries make up the major sources of employment in Key West.

The following subsections present a summary of existing conditions common to all Parcels located at Key West.

1.4.1 Climate and Meteorology

Of the Florida Keys, the Lower Keys have the least rainfall with an average annual rainfall of 39.4 inches. Temperature is fairly uniform across the Florida Keys with a July average temperature of 84 degrees Fahrenheit (°F), a January temperature of 64 to 70°F, and an average annual temperature of 76.3°F. Freezing temperatures are rare in the Florida Keys due to their proximity to the Gulf Stream and the Gulf of Mexico, both of which modify advancing cold fronts. Freezes, when they occur, have the long-lasting effect of killing cold-sensitive species that might otherwise become established. Easterly tradewinds and sea breezes suppress summer heat from June to September (B&R Environmental, 1998a).

Hurricanes normally form in the warm, moist air over the tropical seas around the Lesser Antilles and occasionally in the Caribbean. They tend to move in a westerly to northwesterly direction, gradually turning northward and eastward. Most hurricanes that approach Key West do so from the south and east. Severe hurricanes have struck Key West from each direction. Tidal flooding causes an estimated 75 percent of all damage that occurs during a hurricane (B&R Environmental, 1998a).

Dry and wet seasons characterize the climate of Key West. From December through May, the Keys receive approximately 20 to 25 percent of their total annual precipitation. Approximately 75 to 80 percent of the annual rainfall occurs from June through November. Rainfall usually occurs in advance of a cold front in the form of a few heavy showers, with generally five to eight light showers per month. Overland flow or storm drains that drain approximately 50 percent of the island's surface area carry rainfall runoff

from Key West to the tidal waters; however, much of the rainfall percolates directly into the subsurface (B&R Environmental, 1998a).

1.4.2 Topography

Key West lies in the southeastern Coastal Plain physiographic province. A series of ancient marine reefs, formed during the Pleistocene period when the sea level was higher than it is at present, control the topography of the Coastal Plain in southern Florida (B&R Environmental, 1998a).

Ground elevations on Key West average between 4 and 5 feet (ft) above mean sea level (msl), and the highest point on Key West is approximately 14 ft above msl. Key West is characterized by a sparse veneer of residual soil and surface vegetation overlying eroded limestone. The topography of the lower Keys, generally smooth and flat in the center of the key, slopes gently toward the shoreline. Except in the filled areas that underlie the Overseas Highway, Key West is generally flat. With the exception of central Key West, most areas are within the 100-year floodplain (B&R Environmental, 1998a).

1.4.3 Surface-water Hydrology

The surrounding saltwater bodies, the Atlantic Ocean and the Gulf of Mexico, dominate the surface-water regime in the Florida Keys. FDEP classifies surface water in the Florida Keys as Class G-III Waters - Recreational, Propagation, and Management of Fish and Wildlife. In the immediate area of Key West are the Great White Heron National Wildlife Refuge and the Key West National Wildlife Refuge, which FDEP classifies as Outstanding Florida Waters to receive the highest degree of protection by the State. The residents of Florida consider these waters of exceptional recreational and ecological significance (B&R Environmental, 1998a).

Freshwater recharge in the lower Keys occurs directly through rainfall. The nearly flat topography and porous nature of exposed limestone allows much of the rainfall to infiltrate to shallow groundwater tables, forming freshwater lenses. Overland flow or storm drains in most of the more developed areas carry remaining rainfall to tidal waters. Accelerated runoff and increased saltwater intrusion from canals, housing, dewatering (as a mosquito control measure), and marinas decrease the freshwater lens on the Florida Keys and affect water quality. During the dry season, freshwater tends to disappear quickly by seepage to the sea and evaporation. Evaporation exerts an important effect on the Florida Keys' hydrologic budget, with transpiration affecting a more localized and confined area on individual islands (B&R Environmental, 1998a).

1.4.4 Geology and Soil

The lower Keys, which are within the southern or distal geomorphic division of Florida, were formed during the Pleistocene era. Commonly referred to as the "Oolite Keys," they are underlain by the Oolitic Member (Miami Oolite) of the Miami Limestone. The Oolitic Member consists of variably sandy, fossiliferous limestone composed primarily of ooids (spherical calcareous grains 0.25 to 2.0 millimeters [mm] in diameter) that were created through eustatic elevation of the limestone. In the lower Keys, the Oolitic Member consists of the Ooid Calcarenite and the Oomoldic-recrystalline lithofacies. The Ooid Calcarenite lithofacies consist of very fine to coarse sand-size, spherical carbonate grains concentrically laminated around a silt-size to fine-sand-size nucleus. The Oomoldic-recrystalline lithofacies consist of slightly sandy to very sandy well- to moderately well-consolidated micritic calcite. The Miami Oolite overlies the Key Largo Limestone, a geologic unit consisting of light grey to light yellow coralline limestone comprised of coral heads encased in a matrix of calcarenite.

The Miami Oolite is reported to be 27 ft thick. The Key Largo limestone is greater than 270 ft thick in the western portion of Key West. The Key Largo Limestone is generally more porous than the Miami Oolite, but it contains only saltwater. Figure 1-3 shows a geologic cross-section of the Florida Keys.

Many areas of the Florida Keys have been filled and graded. Undisturbed soil in the Keys consists of shallow marl over limestone with the substrate rock outcropping at the surface.

1.4.5 Hydrogeology

The surficial aquifer system in the lower Keys consists of the Oolitic Member, which is very porous and highly permeable due to the dissolution of carbonate by groundwater as it recharges the aquifer system. The aquifer is tidally controlled and fluctuates constantly. Solution holes and caverns are ubiquitous. The Tamiami Formation lies below the Key Largo Limestone unit, between 300 and 900 ft below land surface (bls). The formation contains mineralized water that does not meet Florida drinking water standards. Underlying the Tamiami Formation are the Hawthorn and Tampa Formations, which together act as an aquiclude confining the underlying limestone units. Below the confining units of the Hawthorn and Tampa Formations is the Suwannee Limestone, fossiliferous limestone representing the top of the water-producing zone in the Florida Keys. The Avon Park Limestone is 1,300 ft bls and, although it has a higher transmissivity than the Suwannee Limestone and supplies large quantities of drinking water in central Florida, is of poor quality in the Florida Keys (B&R Environmental, 1998a).

The surficial aquifer is the principal aquifer of concern in Key West because of its reported use as a potable water resource to a limited extent (although not at NAS Key West) and because of its

groundwater-to-surface-water contaminant migration route (ABB, 1995). The water table ranges in depths from 0.8 to 2.4 ft above msl at the center of Key West and from 0.4 to 2.2 ft above msl near the coast. The water table fluctuates diurnally because of tidal effects. Head differentials associated with tidal variations near the shore can further accelerate groundwater movement in the area. A reconnaissance water-quality sampling study completed in 1990 by the U.S. Geological Survey in cooperation with the South Florida Water Management District indicates that the freshwater lens contains nonpotable water (B&R Environmental, 1998a). The State of Florida classifies groundwater in unconfined aquifers that have a total dissolved solids content of 10,000 milligrams per liter (mg/L) or greater as Class G-III (nonpotable water). The City Engineer of Key West reports that water from some wells in the surficial aquifer might be used for drinking after treatment such as reverse osmosis. The freshwater lens averages 5 ft in thickness below the center of the western half of Key West. The lens contains between 20 and 30 million gallons of fresh water, depending on the season. Underlying the freshwater lens is a 40-foot transition zone of brackish water (B&R Environmental, 1998a).

1.4.6 Potable Water Supply

Potable water is supplied to all the Florida Keys. The Florida Keys Aqueduct Authority (FKAA) operates and maintains the Florida Keys Aqueduct that supplies potable water throughout the Florida Keys. The water is drawn from wells near Florida City in southeastern Dade County and pumped 130 miles through a water main that parallels U.S. Highway 1 and terminates in Key West. Water is distributed along the length of the main. In 1984, the FKAA supplied the City of Key West with an average flow of 11.7 million gallons per day (mgd). The Navy at NAS Key West received 14.35 percent of the average flow (B&R Environmental, 1998a). In some instances, potable water also is obtained by rainwater catchment (the only source prior to the construction of the pipeline in the 1940s).

Alternative sources of potable and nonpotable water in the Florida Keys include private cisterns, private wells, home desalination systems, and bottled water. The Monroe County Health Department recognizes the public water supply as the only potable water source available on Key West. In addition to managing the centralized public water supply system, the FKAA has the authority to regulate all potable water supplies in the Keys, including alternative sources of water such as those mentioned above. Those residences using a dual system of private and public water are required to use a reduced-pressure valve to prevent back-flow of water into the water supply system. The FKAA does, however, report that private wells in the freshwater lens in the surficial aquifer may be used for both potable and nonpotable purposes (B&R Environmental, 1998a). The number of people who use water from private wells in Key West for drinking or nonpotable domestic purposes is unknown. The best estimate of the number of people using local groundwater for nonpotable domestic purposes is less than 500 people (B&R Environmental, 1998a).

1.4.7 Key West Population and Land Use

The City of Key West has a residential population of approximately 24,800 (USCBS, 1990). The principal industry is tourism with approximately 1.5 million tourists visiting the city annually (Roberts, 1998). The Monroe County population is approximately 78,000, and the average age is approximately 39 years (USCBS, 1990). The average household size is 2.3 persons. The median cost of housing is \$164,000. Key West has five elementary schools, three parochial elementary schools, one public high school, the Florida Keys Community College, and May Sands Exceptional Center. Monroe County has 33 churches, one synagogue, and two Florida Health System Hospitals (east and west). Land use in the City of Key West consists primarily of commercial and residential areas.

1.4.8 Key West General Area Ecology

Key West includes areas that have been developed by the Navy and retain little natural resource value. Of the BRAC Parcels addressed in this report, the five Truman Annex Parcels, and the Trumbo Point Parcel are considered fill areas with no natural communities. However, some abandoned areas still support high-quality natural communities and provide important habitats. Five non-marine natural community types have been identified within the NAS Key West study area (FNAI, 1994). The only known elements of the mangrove swamp and coastal rock barren communities on Key West occur on the BRAC Parcels Hamaca Hawk Missile Site and East Martello Battery. These two natural community types are described below.

1.4.8.1 Mangrove Swamp

Four plant species dominate these areas: red mangrove (*Rhizophora mangle*), black mangrove (*Avicennia germinans*), white mangrove (*Laguncularia racemosa*), and buttonwood (*Conocarpus erecta*). The relative abundance of each species varies greatly from area to area as do the density, average height, degree of canopy closure, and diversity of associated herbaceous species. Mixed mosaics of mangrove species make up the majority of mangrove swamps at NAS Key West, which vary continuously over a given area with regard to species dominance. A mangrove swamp exists on the eastern half of the Hamaca Hawk Missile Site Parcel. A narrow fringe of mangrove swamp habitat occurs along the water's edge on the southern and eastern portion of the East Martello Battery Parcel (FNAI, 1994).

1.4.8.2 Coastal Rock Barren

Coastal rock barrens are generally characterized as flat rocklands with much exposed and eroded limestone, sparsely vegetated with stunted, xeric, and halophytic (salt-adapted) shrubs, cacti, algae, and

herbs. Buttonwood in some form often dominates this community. It can vary from bonsai-like sprawling shrubs less than 30 centimeters (cm) in height growing with two or three other stunted halophytes on essentially bare rock pavement to erect, multi-trunked 10-m-tall trees growing on deeper marls and associated with a rich variety of xerophytic shrubs, trees, cacti, graminoids, and forbs. Typical species include saffron plum (*Bumelia celastrina*), Christmas berry (*Lycium carolinana*), cat's claw (*Pithecellobium keyense*), erithalis (*Erithalis fruticosa*), bay cedar (*Suriana maritima*), indigo berry (*Randia aculeata*), wild dilly (*Manilkara bahamensis*), poisonwood (*Metopium toxiferum*), seagrape (*Coccoloba uvifera*), joewood (*Jacquinia keyensis*), rhacoma (*Crossopetalum rhacoma*), Spanish stopper (*Eugenia myrtoides*), saltgrass (*Distichlis spicata*), fimbristylis (*Fimbristylis castanea*), and Porter's broom spurge (*Chamaesyce porteriana* var. *scoparia*). In these sites, the coastal rock barren becomes a relatively dense thorn scrub thicket of sclerophyllous vegetation that typically includes epiphytic bromeliads and orchids.

At NAS Key West, coastal rock barren occurs in both the open pavement rockland form and in the deeper marl thicket form. Widely disparate forms of this community type at NAS Key West support populations of various vascular plants and vertebrates.

Remnants of this habitat appear to exist on the northwestern portion of the Hamaca Hawk Missile Site property beyond the site fence line and on the northwestern portion of the East Martello Battery property although it has been impacted by the invasion of Australian pine (FNAI, 1994).

1.4.8.3 Wildlife

As expected, wildlife at NAS Key West vary considerably depending on habitat. Developed areas of Key West limit wildlife primarily to birds associated with urbanized areas. A variety of species, however, use the relatively undisturbed habitats (particularly mangrove swamps and lagoons).

An 11-month field study observed 126 species of birds at NAS Key West (FNAI, 1994). As many as 300 species of birds might use habitats on the base either as migrants or residents (Schuetz, 1996). Biologists observed four snake and three lizard species during the Florida Natural Areas Inventory (FNAI) study at NAS Key West: the black racer (*Coluber constrictor*), red rat snake (*Elaphe guttata guttata*), Eastern diamondback rattlesnake (*Crotalus adamanteus*), rough green snake (*Ophiodrys aestivus*), Florida Keys mole skink (*Eumeces egregius egregius*), Carolina anole (*Anolis carolinensis*), and brown Cuban anole (*A. sagrei*) (FNAI, 1994). Biologists previously observed the endangered Eastern indigo snake (*Drymarchon corais couperi*) (FNAI, 1994); this and other reptiles and amphibians undoubtedly occur on the base.

Very few mammal species occur on Key West and in the lower Florida Keys. Only three native mammal species were observed during the FNAI study: the Lower Keys marsh rabbit (*Sylvilagus palustris hefneri*), the raccoon (*Procyon lotor*), and the opossum (*Didelphis virginianus*) (FNAI, 1994). Raccoons are abundant and widespread on the base, while opossums are uncommon.

Relatively harsh natural ecological conditions in the Keys (i.e., poor soils, scarcity of fresh water) likely ensure a low species diversity of mammals. In addition, humans have extensively altered or destroyed natural habitats, so remaining natural habitats occur in small isolated patches. Exotic species such as Australian pine have invaded and thus significantly altered many natural areas.

Carnivorous mammals at NAS Key West are limited to raccoons and feral cats. No moles or shrews live on the base, and few rodent species occur there. Neither the eastern harvest mouse (*Reithrodontomys humulis*) nor the cotton mouse (*Peromyscus gossypinus*), both common in most of Florida, occur on the base. Native terrestrial mammals on the base appear to be limited to raccoons, marsh rabbits, opossums, and cotton rats (*Sigmodon hispidus*).

1.4.8.4 Threatened and Endangered Species

Tables 2-1 and 2-2 in the SI Workplan (B&R Environmental, 1998a) present Federal and State-listed threatened and endangered species recorded at NAS Key West (FNAI, 1994). A few listed threatened and endangered species not recorded on these tables undoubtedly occur on the base but have not been reported to FNAI. For example, Truman Beach (part of the Truman Annex Parcel) has been documented as a nesting area for the threatened loggerhead sea turtle (*Caretta caretta*) (BAP, 1997). The mangrove rivulus (*Rivulus marmoratus*), a minnow that is a state-listed Species of Special Concern (SSC), could potentially occur in mangrove swamps at East Martello Battery and Hamaca Hawk Missile Site.

The West Indian manatee is occasionally observed in waters adjacent to the Truman Annex Parcel (BAP, 1997). Other listed species occurring on or near the Truman Annex Parcel include least terns, Roseate terns, and ospreys.

Wooded areas at the East Martello Battery and Hamaca Hawk Missile Site Parcels provide potential nesting and roosting habitat for the white crowned pigeon, a state-listed threatened species.

Wading birds such as little blue herons, snowy egrets, tricolored herons, reddish egrets, and white ibis (all state-listed as SSC) are commonly observed foraging in lagoons, ditches, and other aquatic habitats at East Martello Battery and Hamaca Hawk Missile Site Parcels, as well as along the shoreline at the Truman Annex Parcels.

Bald eagles and ospreys are occasionally observed in the vicinity of the East Martello Battery and Hamaca Hawk Missile Site Parcels.

The East Martello Battery and Hamaca Hawk Missile Site Parcels are believed to be the only locations on NAS Key West where endangered or threatened plant species might occur (BAP, 1997).

1.5 FIELD PROCEDURES

All methods and procedures employed in the course of the field investigation are discussed in the BRAC SI Workplan (B&R Environmental, 1998a). Any change in methodology from that stated in the workplan, usually due to unexpected field conditions, is addressed in Appendix B. Issues and procedures that are addressed by the BRAC SI Workplan include the following:

- Data management
- Decontamination
- Documentation
- Equipment
- Health and safety
- Investigation derived waste (IDW)
- Monitoring well installation
- Project management
- Sample collection, handling, and analysis
- Surveying
- Quality assurance

1.6 DATA MANAGEMENT

In 1997, the DQO Process (EPA, 1994) was used as a tool by the NAS Key West Partnering Team to determine the type, quantity, and quality of data needed to support the development of the BRAC SI Workplan. The DQO Process was performed on the 10 BRAC Parcels categorized as grey. As a systematic planning tool based on the scientific method, the seven-step DQO Process helps establish criteria for defensible decision-making at the onset of a study and develops a data-collection design based on these criteria. The DQO Process also helps develop recommendations based on SI findings for each Parcel. The NAS Key West Partnering Team is made up of the key decision makers for environmental restoration and remediation at NAS Key West. The members include representatives from the FDEP, EPA, NAVFACENGCOM-Southern Division, the U.S. Navy at NAS Key West, and the U.S. Navy's remedial and investigative contractors.

In the initial steps of the DQO Process, all existing site data were reviewed and it was determined that based on site history, a number of subzones could be eliminated from further investigation. It was determined that contamination at several other subzones was already being addressed elsewhere (e.g., primarily by the underground storage tank [UST] program) or was well enough characterized to consider the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) assessment process complete. Table 3-1 of the BRAC SI Workplan provides a summary of all subzones that were eliminated during the DQO Process. These subzones will not be addressed in this report.

The seven steps of the DQO Process identify such information as the goal of the investigation, the inputs needed to reach the goal and make a decision, the temporal and areal boundaries of the investigation, the level of confidence required to support a decision, and finally, a sampling design that is adequate to support the decision-making process. A complete discussion of each step of the DQO Process as it relates to the BRAC SI is provided in Section 3.0 of the BRAC SI Workplan. Important elements of the DQO Process include the following:

- Identification of subzones that do not require additional data (i.e., SI sampling and analysis)
- Identification of the medium (e.g., soil, sediment, surface water, and groundwater) and parameters (volatile organic compounds [VOCs], semivolatile organic compounds [SVOCs], inorganics, pesticides, and polychlorinated biphenyls [PCBs]) of interest in each subzone
- Selection of analytical methods
- Selection of action levels
- Constraints on data collection
- Quantifying the desirable level of confidence in decisions
- Determining sample size for each medium

1.7 DATA QUALITY ASSESSMENT

Maintaining and assuring data quality was a key issue in all stages of the data-handling process. Accordingly, procedures were in place in each step of the process to ensure the integrity of the sample data generated during the SI field investigation. Each portion of the data-handling process, including data generation at the laboratory, data review, and database assembly is discussed below.

1.7.1 Laboratory Quality Assurance

Laboratory quality control (QC) procedures are designed to ensure the consistency and continuity of the data. Standard QC analyses were performed throughout laboratory handling of the BRAC SI samples. This included the routine analysis of matrix spike and matrix duplicate samples, laboratory method blanks, and laboratory control samples. Laboratory instrument calibrations were performed and verified based on the requirements of the individual analytical methods. In order to ensure that data quality standards were met or surpassed, laboratory personnel reviewed all QC procedures and analyses prior to the completion of data packages. Appendix D (Quality Assurance Elements) of the BRAC SI Workplan provides a more detailed discussion of laboratory quality assurance requirements and procedures (B&R Environmental, 1998a).

1.7.2 Data Review

All data packages submitted by the laboratory underwent a formal data review that included the following elements:

- Complete verification of the electronic results against the Chain of Custody (COC) and the result reported on the Certificates of Analysis (COA)
- Review of holding times
- Review of all blank samples submitted as a routine part of the sample collection process (trip blanks, field blanks, and rinsate blanks) in order to eliminate false positives
- Review of laboratory calibration logs for gross non-compliance with QC requirements

1.7.3 Database Assembly

Once the review process of the SI data packages was completed, the electronic data was assembled in a database in order to facilitate the interpretation and analysis of results. A series of electronic checks were performed and documented in order to ensure the integrity of the data set. This included confirming the presence of each sample in the database, demonstrating that the appropriate analytical fractions were present for each sample, verifying consistent sample and parameter nomenclature in the electronic data set, checking units for consistency, and reviewing key fields for blank or other inappropriate entries. The electronic QC process also identified duplicate samples, generated an average result for each duplicate location, and verified that only one set of results for each location was accepted into the final data set.

1.8 SITE INSPECTION METHODOLOGY

An overview of the methods used to interpret and present the analytical data is provided here. Sections 2 through 9 of the BRAC SI Report present the results of the field investigation. These sections include a discussion of each subzone investigated and present the contaminants that were detected during the investigation.

1.8.1 Site Characterization

Each Parcel-specific report section begins with a brief historic account of the Parcel's uses and activities, its geographic and physical features, a description of any previous investigations, and the rationale and scope of the SI. Each section is then further broken down into subzone-specific subsections. Each subsection provides a description of the specific area being addressed and details the findings at that location. Each subsection contains conclusions which evaluate the findings and recommend an appropriate course of action. The subzone-specific conclusions are summarized in an overall Parcel conclusions and recommendations at the end of each section.

1.8.1.1 Determination of Background Levels

In 1996, a comprehensive background data set was assembled for use as a tool in the Supplemental Resource Conservation and Recovery Act Facility Investigation/Remedial Investigation (RFI/RI) Report for Eight Sites (B&R Environmental, 1998d). At that time the background data set was used to characterize the nature and extent of contamination and to assist in the performance of ecological and human health risk assessments at the eight sites that were investigated. A subset of the background data set was used during the DQO Process to statistically determine subzone sample sizes and to screen data from the BRAC SI.

For consistency and comparability, all data included in the BRAC SI background data set were collected over the same time period and analyzed by the same laboratory. Background levels were calculated based on chemical-analytical data from background samples collected in the vicinity of Key West, Florida. The entire BRAC SI background data set can be found in Appendix B of the BRAC SI Workplan (B&R Environmental, 1998a). The Comprehensive Background Report, Appendix F of the Supplemental RFI/RI for Eight Sites (B&R Environmental, 1998d) provides a complete discussion of how calculations were performed and how background data were identified.

1.8.1.2 Modifications to the Parcel Data Sets

In general, the electronic data set developed for site characterization and analysis directly reflects the information presented in the laboratory data packages. A few modifications and exclusions were necessary, as follows:

- Data from field duplicate samples were averaged in order to obtain a single set of results for each sample location within a given investigation. The individual duplicate results were maintained in the electronic database for completeness, but only the calculated averages were used in site characterization and analysis.
- A standardized set of parameter names was used throughout the data set, and the assignment of parameters to analytical fractions was also standardized.
- As described in Section 1.7.2, all analytical results underwent data review, which occasionally resulted in changes to the data set.

1.8.2 Development of Site Investigation Findings

The detected chemicals were considered at the subzone level for each Parcel. All of the analytes were compared to action levels for appropriate media, and the analytes determined to exceed the selected action levels are the primary focus of the discussion. The compounds that exceeded the action levels are shown on maps associated with the subzone-specific discussion of contamination findings. For reference, all detected parameters are presented in the data tables that accompany the discussion.

1.8.2.1 Action Levels

Applicable or Relevant and Appropriate Requirements (ARARs) and Screening Action Levels (SALs) were obtained from various state agencies, Federal agencies, and research institutions. These values were considered as potential screening criteria in evaluating the SI findings at each Parcel. Either a residential or industrial set of action levels was considered for each Parcel based on its future use designation as defined in the Draft Key West Base Reuse Plan (BAP, 1997). Twice the average background concentration (as discussed in Section 1.8.1.1) was used as an additional screen. All potential action levels considered for soil, sediment, surface water, and groundwater are presented in Appendix B of the BRAC SI Workplan (B&R Environmental, 1998a). The last columns of each table identify the value selected for use in screening the parameters detected in each medium.

Legally binding action levels, guidance values, and potentially applicable guidance values from other media were all evaluated as part of action level selection in the DQO Process. For inorganics, commonly found in background samples from the vicinity of NAS Key West, twice the average background concentration was also considered as a potential action level. The decision logic used to compare these various values and select the action levels is shown in Figure 1-4.

Several new soil and groundwater action levels have been developed since the BRAC SI Workplan. Chemicals with new action levels include thallium, phenanthrene, and 2-hexanone. Residential and industrial soil action levels for thallium are 5.5 mg/kg (EPA, 1998) and 140 mg/kg (EPA, 1998), respectively. For 2-hexanone, these soil action levels have been established as 3.4×10^6 $\mu\text{g}/\text{kg}$ (EPA, 1997) for residential and 8.2×10^7 $\mu\text{g}/\text{kg}$ (EPA, 1998) for industrial. The groundwater action level for 2-hexanone is 4.28×10^5 $\mu\text{g}/\text{L}$ (EPA, 1995b) and for phenanthrene is 8.3 $\mu\text{g}/\text{L}$ (EPA, 1996b). Risks calculated for naphthalene compounds have been determined negligible. Therefore, FDEP no longer has established action levels for naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene. Detections of these chemicals will not be considered exceedances at NAS Key West.

Thallium results from the SI data set have been reviewed to verify their accuracy. A revalidation was performed for inorganic data and the conclusion was drawn that there is no indication that the results for thallium are incorrect. However, due to the consistency of the detection levels and frequency that thallium was detected (70.4 percent), it appears that a systematic equipment error is responsible for the detections. During supplemental SI field investigations, thallium was not detected in BRAC Parcels where thallium was detected during the SI. The NAS Key West Partnering Team agreed during its October 1998 meeting that thallium detections reported during the SI are suspect and will not be used to drive further action.

1.8.2.2 Estimated Risk Process

As discussed in Section 3.2 of the BRAC SI Workplan (B&R Environmental, 1998a), consistent and appropriate recommendations must be made for subzones where action levels are exceeded. These risk estimates are not considered human health or ecological risk assessments; instead the estimates were used to give the decision-makers an idea of the magnitude of the risks posed by certain chemicals. Estimated risks were calculated for chemicals detected in excess of their action levels. Estimates were based on maximum detected concentrations. Human health risk estimates for soil, sediment, and surface-water subzones were calculated from the Supplemental RFI/RI human health risk assessments (B&R Environmental, 1997a and 1998d) where risk values were available for compounds in question. For each subzone, risk estimates were based on either residential, trespasser, or site/occupational worker scenarios based on subzone future use as described in the Base Reuse Plan (BAP, 1997). When one or

two risk values were available for a given chemical, estimates were based on a ratio of detected concentrations and risk values. When three or more risk values were available for a given compound, estimates were calculated from a trend analysis. In instances where risk values were not available from the RFI/RIs for a given compound, generic remedial goal options (RGOs) were used as benchmarks. Either a residential or industrial risk based concentration was used based on each subzone's future use as described in the Base Reuse Plan (BAP, 1997). Appendix C contains supporting documentation for risk estimation calculations.

Ecological risks were characterized for sediment, surface-water, and groundwater subzones. Groundwater-to-surface-water migration of groundwater contaminants is possible at NAS Key West, especially since groundwater is shallow. However, ecological receptors are not directly exposed to groundwater, and no groundwater thresholds have been developed based on ecological concerns. Therefore, groundwater concentrations of chemicals that exceeded action levels were compared to surface-water screening values (where available) as a conservative scenario (e.g., no attenuation or dilution) in accordance with EPA Region 4 (EPA, 1995a) and FDEP requirements (FDEP, 1996a). Factors such as frequency of detection, frequency of samples that exceeded action levels, comparison to background (for inorganics), and magnitude of exceedances were used in assessing ecological risks.

As in the groundwater analysis, factors such as frequency of detection, frequency of samples that exceeded action levels, comparison to background (for inorganics), and magnitude of exceedances were utilized in assessing ecological risks in sediment and surface water. In addition, concentrations of analytes in surface water and sediment that exceeded action levels were compared to other screening values (where available). For example, sediment chemicals that exceeded action levels were compared to effects range-low (ER-L) and effects range-median (ER-M) values developed by the National Oceanic and Atmospheric Administration, as well as to threshold effects level (TEL) and probable effects level (PEL) values developed by FDEP. Any screening levels used in addition to action levels are provided in the text or in Appendix C.

1.8.2.3 Data Tables

Data tables are included within each subzone-specific discussion. Each table lists only the chemicals that were detected in the specific subzone being discussed. These tables provide an inclusive list of the analytes detected at the parcel by subzone. Data validation qualifiers are provided in these tables and are defined at the end of each table. Rejected data are not included.

As stated in the BRAC SI Workplan (B&R Environmental, 1998a), the common essential nutrients calcium, magnesium, potassium, and sodium are not addressed in the SI Report, although some samples were analyzed for these parameters.

1.8.2.4 Contaminant Distribution Maps

Maps were created to present the concentration and distribution of the analytes detected in excess of action levels for each parcel, by subzone. The purpose of these maps is to illustrate the distribution and extent of contaminants, to identify areas of greatest impact, and to link the release and, if applicable, the migration of contaminants to the Parcel's physical features and/or environmental setting. Chemical concentrations are shown at each sampling point where an action level was exceeded. Other considerations made during the preparation of the contaminant distribution maps are:

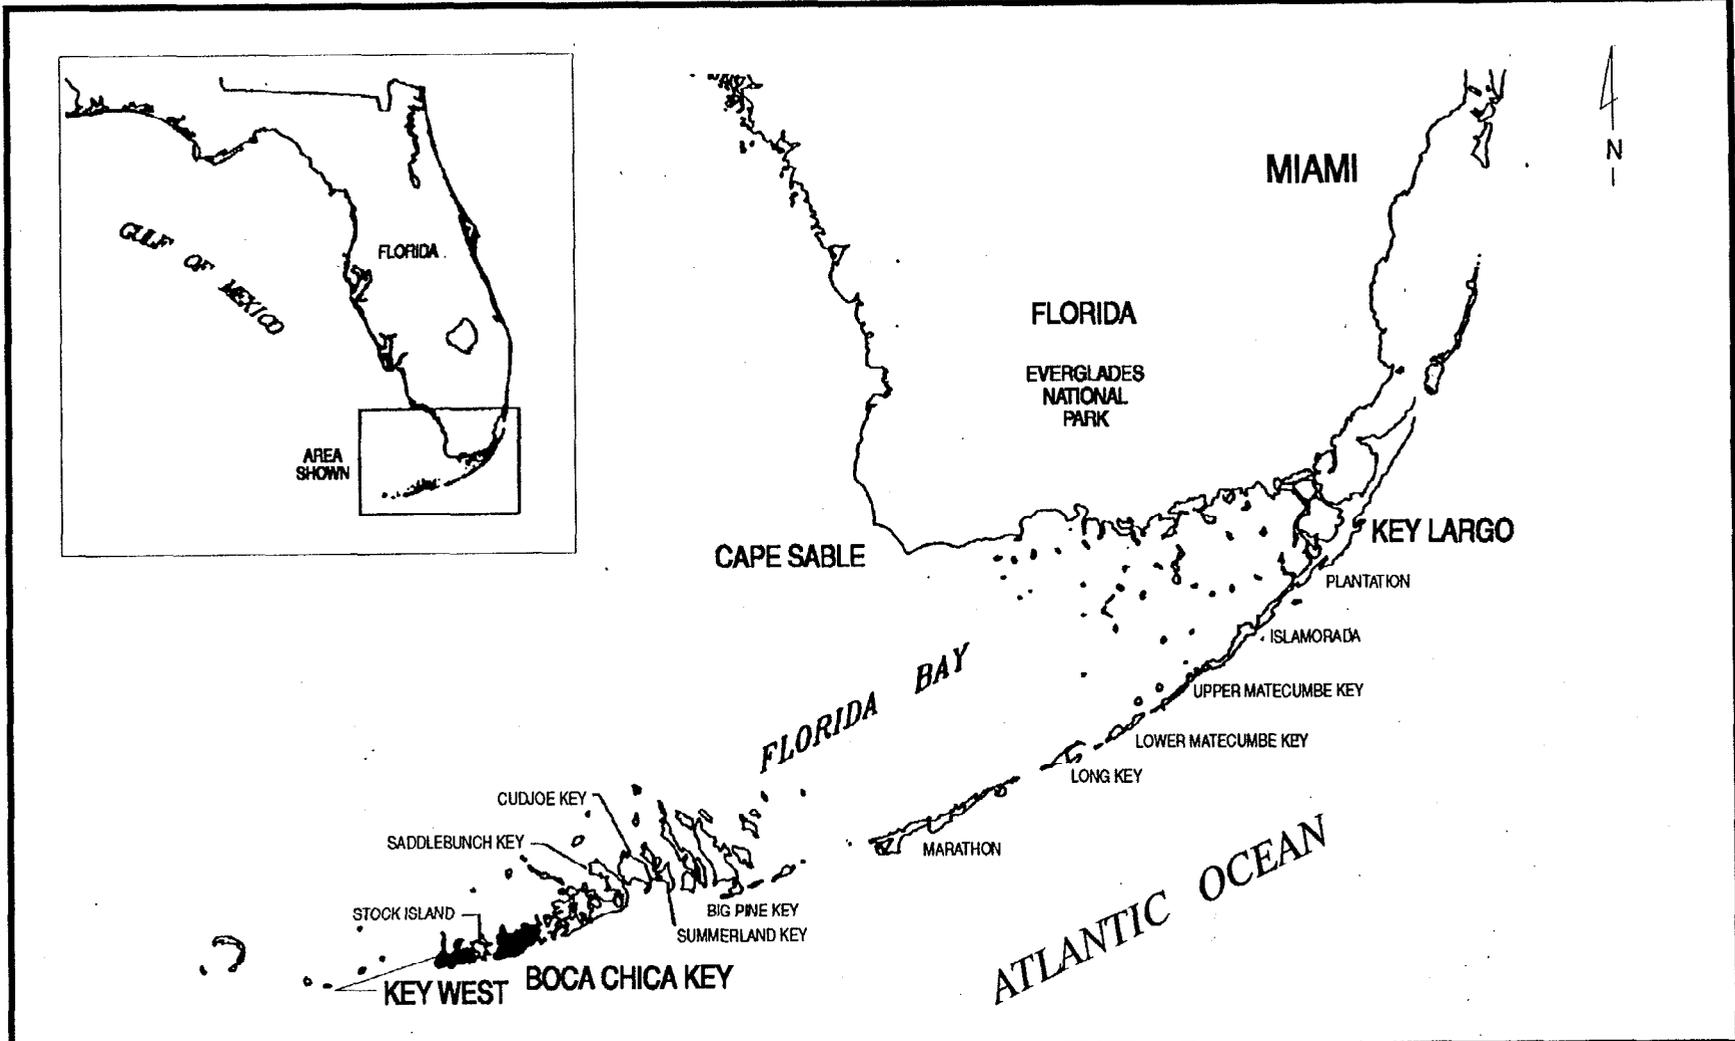

- Non-detect data and data that fell below the action level for a given chemical are not represented on the maps.
- A data box on each map provides the action levels that were used as a basis of comparison for each chemical shown. Appendix B of the BRAC SI Workplan (B&R Environmental, 1998a) provides an inclusive list of all the ARARs, SALs, and background values that were evaluated as potential screening criteria for the SI findings discussion.
- For sediment and soil, laboratories commonly report organic concentrations in micrograms per kilogram ($\mu\text{g}/\text{kg}$), while inorganic concentrations are reported in milligrams per kilogram (mg/kg). These standardized units are maintained throughout the text, tables, and maps.
- Concentrations of contaminants in groundwater and surface-water contaminants are normally reported in micrograms per liter ($\mu\text{g}/\text{L}$). These standardized units are maintained throughout the text, tables, and maps.
- The maps distinguish between organic and inorganic parameters in order to carry through the standardized units in an easily recognizable, consistent fashion.

1.8.2.5 Conclusions and Recommendations

Conclusions were prepared for each subzone and for each Parcel to summarize the SI findings. Recommendations based on the findings were developed for each Parcel in cooperation with the NAS Key West Partnering Team and in accordance with the DQO Process (B&R Environmental, 1998a).

2.0 HAMACA HAWK MISSILE SITE (PARCEL A)

2.1 PARCEL DESCRIPTION

Based on historical maps and aerial photographs, the land used for the Hamaca Hawk Missile Site was previously salt ponds that were filled by the U.S. Army in order to use the area as a missile site (Figure 2-1). This facility was built in 1964 as a defense site as a result of the Cuban Missile Crisis. It was used for coastal defense until the early 1980s when it was transferred to the Navy. The Navy did not use the property but allowed homeless veterans to stay there in 1994 and 1995. During the 10 months the Vietnam veterans occupied the site, wastewater from showers and washing machines was discharged into the surrounding wetlands.

The Hamaca Hawk Missile Site is bordered to the south by Key West International Airport, where petroleum products are stored and used. The northern border is the Flagler Canal, a man-made canal connected to the Atlantic Ocean. The canal is used by private boats and appears to overflow onto the site at times. Woodlands and wetlands border the property to the east and west.

2.2 INVESTIGATION HISTORY

This section describes previous and current investigations for the Hamaca Hawk Missile Site Parcel.

2.2.1 Previous Investigations

Existing documents include the United States Navy-Naval Public Works Center (USN-NPWC) Lead and Asbestos Survey of Hamaca Hawk Missile Site (USN-NPWC, 1995a), the United States Navy-Supervisor of Shipbuilding Conversion and Repair, Environmental Detachment (USN-SUPSHIP) Predraft EBS Realignment Parcels (USN-SUPSHIP, 1996), the Hamaca Hawk Missile Site Contamination Assessment Report (CAR) (BBL, 1997), and the Supplemental Assessment Report (SAR) (BBL, 1998). No previously existing soil, sediment, surface-water, or groundwater analytical data was included in the analysis of potential contamination at the Hamaca Hawk Missile Site Parcel.

Based on the 1995 inspection performed by the NPWC, both lead based paint (LBP) and asbestos-containing building materials (ACBMs) are present in the Hamaca Hawk Missile Site facilities and infrastructure. The CAR and SAR reported on the investigation of a discharge of diesel fuel in the subzone 2 area at the former 2,000 gallon above ground storage tank (AST). These reports concluded a finding of no further action.

The EBS (USN-SUPSHIP, 1996) documented a number of factors that potentially are helpful in characterizing the current physical condition of the site.

- Although the storage of hazardous or petroleum substances at the site in the past has been documented, no visible sheen or discoloration of surface water has been observed.
- No stains were observed on site soils, although old stains of an indeterminate nature were found on the floors of several site facilities.
- At one time, two ASTs in bermed foundations were used for fuel oil and/or diesel storage. Both of these ASTs have since been removed, although there are currently several other empty ASTs located at site. Two of these tanks, located north of Building I-6504, contained water. Two other empty tanks, sitting on the asphalt drive, were apparently moved from an unknown location by Vietnam veterans.
- Vandalism of three on-site transformers, abandoned by the Army, resulted in a small PCB spill. Initial testing by the Navy showed very low PCB concentrations in soil, and subsequent tests did not indicate any PCB contamination.
- Although pesticides are commonly used for mosquito and pest control throughout NAS Key West, there is no evidence of pesticide misuse at the site.
- A water storage tank and sewage pumping station are located on-site but have not been operable for many years.

2.2.2 Current Investigation

The DQO Process evaluated 13 subzones for the Hamaca Hawk Missile Site Parcel. Subzones 2, 3, 8, 12, and 13 were eliminated from further consideration. Eight subzones within Parcel A required sampling and analysis under the BRAC SI. The environmental medium of each subzone and the parameter groups selected for analysis are presented in Table 2-1. Subzone 1 (Drainage Area), subzone 4 (Sewage Lift Station), subzone 5 (Generator Building I-6536), subzone 6 (Burnt Building I-6530 – Former Missile Maintenance Bay), and subzone 7 (Former Transformer Storage Area) were identified as soil subzones, and the four sample locations within each subzone are shown on Figures 2-2 through 2-6, respectively. Subzone 9 and subzone 10, both ponds, were identified as sediment and surface-water subzones, respectively. Eight sediment and seven surface-water sample locations were identified in these subzones as shown in Figures 2-7 and 2-8. The placement of three permanent monitoring wells in subzone 11

(Parcel A groundwater) is shown in Figure 2-9. Analytical results for samples collected at Parcel A were compared to a residential set of action levels (see Section 1.8.2.1).

2.3 SUBZONE 1 (DRAINAGE AREA)

The subsections below describe subzone 1, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 1 surface soil.

2.3.1 Subzone Description

Polynuclear aromatic hydrocarbons (PAHs), solvents, and metals were considered potential contaminants at subzone 1 from adjacent site property and possibly the former creosote pole storage area just outside the fenced entrance. Four surface soil samples were collected in subzone 1, which is bounded on the southwest and north by Government Road and on the east by the Hamaca Hawk Missile Site fence. The BRAC SI Workplan depicts the fence as dividing this drainage area in two parts, both within subzone 1. However, during initial sampling visits, it was noted that the area within the fence had standing water. It was determined that sediment sampling would be more appropriate for this part of the site. Therefore, the subzone 1 boundary was redrawn to place the entire soil subzone outside the fenced area (with four samples taken from it). The part within the fenced area was appended to the sediment subzone (subzone 9) and two additional sediment samples were collected there. All of the analytical results can be found in Appendix D.

2.3.2 Site Investigation Findings

Contamination was investigated by analyzing surface soil samples in the drainage area for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals that were detected in the surface soil samples are listed in Table 2-2. Figure 2-2 shows the locations where analytes exceeded action levels and indicate possible surface soil contamination.

A single organic, dibenzo(a,h)anthracene, was detected in excess of its 100 µg/kg action level at SS-01 (122.3 µg/kg). Arsenic was detected at the same sample location (SS-01) at its FDEP residential goal action level, 2.7 mg/kg. Arsenic was also detected at SS-02 but not in excess of its action level.

Several other inorganics and organics were detected in subzone 1. The inorganics detected at levels below their screening criteria included aluminum, barium, beryllium, chromium, copper, iron, lead, manganese, mercury, nickel, thallium, and vanadium. SVOCs detected at levels below their action levels included anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, and pyrene. VOCs detected at subzone 1 at levels below their action levels were acetone and methylene chloride.

2.3.3 Conclusions and Recommendations

PAHs, solvents, and metals were considered to be potential contaminants in surface soil at subzone 1. Arsenic and dibenzo(a,h)anthracene were considered exceedances in the drainage area. Estimated risks were calculated for both chemicals as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-1. The detected concentration of arsenic may be due to data variability and not be indicative of contamination. The dibenzo(a,h)anthracene detection probably resulted from treated telephone poles that were stored in the area. Since the finding most likely resulted from the telephone poles and dibenzo(a,h)anthracene was only detected at one sample location, no further action is warranted.

2.4 SUBZONE 4 (SEWAGE LIFT STATION)

The subsections below describe subzone 4, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 4 surface soil.

2.4.1 Subzone Description

Solvents, metals, and oils were considered to be potential soil contaminants in subzone 4 from the lift station. Four surface soil samples were collected in the immediate vicinity of the sewage lift station inside the fence by Government Road. All of the analytical results can be found in Appendix D.

2.4.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil at the sewage lift station for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 2-3.

Figure 2-3 shows the location of analytes that exceeded action levels and indicated possible surface soil contamination.

One inorganic, arsenic, was detected in excess of its action level. Arsenic was detected at three of the four samples in excess of its 2.7 mg/kg action level (SS-02, 5.7 mg/kg; SS-03, 28.8 mg/kg; and SS-04, 6 mg/kg). Inorganics at subzone 4 that were detected below their screening criteria included aluminum, antimony, barium, cadmium, chromium, copper, iron, lead, manganese, mercury, nickel, thallium, tin, vanadium, and zinc. No VOCs or SVOCs were detected in excess of their screening values. VOCs detected below their action levels included acetone, methylene chloride, and toluene. SVOCs detected below their action levels included 1,2,4-trichlorobenzene and bis(2-ethylhexyl)phthalate.

2.4.3 Conclusions and Recommendations

Potential contaminants at subzone 4 included solvents, metals, and oils from the lift station. Chemicals detected in excess of their action levels were analyzed further in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates for subzone 4 can be found in Appendix C, Table C-1. Carcinogenic and noncarcinogenic risks estimated for arsenic exceeded the FDEP target risks. Due to the nature and risks of chemicals detected in excess of action levels in subzone 4, further action is recommended. Because arsenic was detected in three of the four samples, a permanent monitoring well was installed in this area.

2.5 SUBZONE 5 (GENERATOR BUILDING I-6536)

The subsections below describe subzone 5, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 5 surface soil.

2.5.1 Subzone Description

The generator shelter is located north of the ponds in Hamaca Hawk Missile Site at Building I-6536. Solvents, oils, and metals were considered potential surface soil contaminants because of operations in the generator building. Two soil samples were collected on the north and south sides of the building. All of the analytical results can be found in Appendix D.

2.5.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the sewage lift station for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected

from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 2-4. Figure 2-4 shows the sample locations of all surface soil samples collected at subzone 5.

No chemicals were detected in excess of their action levels. Inorganics detected below their action levels included aluminum, barium, chromium, iron, lead, manganese, nickel, selenium, thallium, and vanadium. No VOCs or SVOCs were detected at levels in excess of their action levels. VOCs detected below their screening criteria included acetone, methylene chloride, tetrachloroethene, and toluene. Bis(2-ethylhexyl)phthalate was the only SVOC detected.

2.5.3 Conclusions and Recommendations

Solvents, oils, and metals were considered to be potential surface soil contaminants from operations at the generator building at Hamaca Hawk Missile Site. However, no chemicals were detected in excess of the screening criteria. Therefore, there does not appear to be significant surface soil contamination at subzone 5. No further action is recommended.

2.6 SUBZONE 6 (BURNT BUILDING-- FORMER MISSILE MAINTENANCE BAY)

The subsections below describe subzone 6, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 6 surface soil.

2.6.1 Subzone Description

The former missile maintenance bay is located in Building I-6530 which previously had burned. Battery acid, metals, and solvents were considered potential soil contaminants in subzone 6 from its use as a missile maintenance area and from burnt contents of the buildings. Four surface soil samples were collected from the southern side of Building I-6530. All of the analytical results can be found in Appendix D.

2.6.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil at the former missile maintenance bay at Burnt Building I-6530 for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and

research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals that were detected in the surface soil samples are listed in Table 2-5. Figure 2-5 shows the sample locations of all surface soil samples collected at subzone 6.

No chemicals were detected at levels in excess of their action levels. Inorganics detected below their action levels included aluminum, barium, chromium, iron, lead, manganese, nickel, thallium, and vanadium. VOCs detected below their screening values included acetone and toluene. 1,2,4-trichlorobenzene was the only SVOC detected.

2.6.3 Conclusions and Recommendations

Potential chemicals in soil were assumed to include battery acid, metals, and solvents from prior use as missile maintenance area and burnt contents of building. However, no chemicals were detected in excess of their screening criteria. Therefore, significant surface soil contamination does not occur at subzone 6. No further action is recommended.

2.7 SUBZONE 7 (FORMER TRANSFORMER STORAGE AREA)

The subsections below describe subzone 7, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 7 surface soil.

2.7.1 Subzone Description

Dielectric fluids from vandalized Army transformers were considered potential soil contaminants in the former transformer storage area. Four surface soil samples were collected at subzone 7. Three samples were from just outside the fenced perimeter of the area and one sample was from the inside the fenced former storage area. All of the analytical results can be found in Appendix D.

2.7.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the former transformer storage area for SVOCs, PCBs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.2 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 2-6. Figure 2-6 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

A single inorganic, thallium, was detected at one location in excess of its 5.5 mg/kg screening criteria. Inorganics detected below their action levels included aluminum, barium, cadmium, chromium, copper, iron, lead, manganese, nickel, thallium, tin, vanadium, and zinc. No VOCs or SVOCs were detected in excess of their action levels. A single PCB, aroclor-1260, and a single SVOC, bis(2-ethylhexyl)phthalate, were detected below their action levels.

2.7.3 Conclusions and Recommendations

Dielectric fluids from vandalized Army transformers were considered to be potential soil contaminants in the former transformer storage area. However, thallium was the only exceedance. As discussed in Section 1.8.2.1, the frequency of detection indicates a systematic equipment error from the lab. Thallium detections will not be used to drive further action. Therefore, no action is needed at the former transformer storage area.

2.8 SUBZONE 9 (PONDS-SEDIMENT)

The subsections below describe subzone 9, present the contaminants detected, compare the detected concentrations with selected sediment screening values, and provide conclusions on the SI findings for subzone 9 sediment.

2.8.1 Subzone Description

Potential sediment contaminant sources include the storage and/or use of petroleum products, solvents, electrical batteries, lead, hazardous waste, and possibly pesticides. During preparation of the BRAC SI Workplan, six sediment sample locations were selected in subzone 9. However, during initial sampling visits, it was noted that a portion of soil subzone 1 within the fenced area had standing water. It was determined that sediment sampling would be more appropriate on this portion. Therefore, the boundary of subzone 1 was redrawn, placing the portion within the fenced area into subzone 9; two additional sediment samples were collected there. Altogether, eight sediment samples were collected from the subzone 9 at Hamaca Hawk Missile Site. All of the analytical results can be found in Appendix D.

2.8.2 Site Investigation Findings

Contamination was investigated by analyzing samples from sediment in the ponds for VOCs, SVOCs, pesticides, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the sediment samples are listed in Table 2-7.

Figure 2-7 shows the location of analytes that exceeded action levels and indicate possible sediment contamination.

Several inorganics were detected in excess of their action levels at subzone 9. Aluminum and vanadium were detected in excess of their action levels at two locations. Barium and zinc were detected in excess of their action levels only at SD-04. SD-01 was the only location where copper was detected in excess of its 18.7 mg/kg action level (20.15 mg/kg). Lead was detected in excess of its 34.18 mg/kg action level at all sample locations. Lead concentrations ranged from 42.5 mg/kg at SD-02 to 466 mg/kg at SD-05. Other inorganics detected but not in excess of their screening criteria included chromium, iron, manganese, and nickel. Two SVOCs, bis(2-ethylhexyl)phthalate and butyl benzyl phthalate, were detected in excess of their action levels at a single location (SD-05). A single pesticide, 4,4'-DDE, was detected in excess of its 2.07 µg/kg action level at SD-05 (3.1 µg/kg) and SD-08 (7.5 µg/kg). No other SVOCs or pesticides were detected in sediment at Parcel A. No VOCs were detected in sediment at subzone 9.

2.8.3 Conclusions and Recommendations

The storage and/or use of petroleum products, solvents, electrical batteries, lead, hazardous waste, and possibly pesticides at Hamaca Hawk Missile Site are potential sources of sediment contamination. Several inorganics were detected in excess of their action levels in the sediment from ponds at this Parcel. Noncarcinogenic risks were estimated for each chemical detected in excess of its action level but none of the detected concentrations for aluminum, barium, copper, vanadium, or zinc were indicative of significant human health risks. Chemicals detected in excess of their action levels in sediment at subzone 9 exceeded ecological guidelines. However, most of them only slightly exceeded their TEL values, or were infrequently detected. Lead in sample SD-05 is the only chemical exceedance that is considered to pose potential ecological risks. In addition to the lead exceedance at SD-05, five chemicals detected in sample SD-05 exceeded the most conservative ecological guidelines; more analytes than in any other sample. Further sampling in the vicinity of sample SD-05 may serve to better characterize the nature and extent of sediment contamination and associated potential ecological risks. A more detailed discussion of potential ecological risks from chemicals detected in sediment at Hamaca Hawk Missile Site Parcel is included in Appendix C. The NAS Key West Partnering Team discussed this subzone and decided that an interim remedial action should be conducted at subzone 9 in conjunction with the IRAs planned for the other subzones. The IRA Workplan (Bechtel, 1998) provides additional information regarding the IRAs planned for the BRAC properties.

2.9 SUBZONE 10 (PONDS-SURFACE WATER)

The subsections below describe subzone 10, present the contaminants detected, compare the detected concentrations with selected screening values, and provide conclusions on the SI findings for subzone 10 surface water.

2.9.1 Subzone Description

Petroleum, battery acid, and lead were considered potential contaminants in surface water from Parcel A runoff. Seven surface-water samples were collected from the ponds at Hamaca Hawk Missile Site. All of the analytical results can be found in Appendix D.

2.9.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface-water in the ponds for SVOCs and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface-water samples are listed in Table 2-8. Figure 2-8 shows the location of analytes that exceeded action levels and indicate possible surface-water contamination.

A single inorganic, iron, was detected in excess of its 300 µg/l action level at all seven sample locations. The maximum exceedance was detected at SW-04 (6,300 µg/l), in the small pond near the western berm area. Other inorganics detected at levels lower than their screening criteria included lead and zinc. No SVOCs were detected in the surface-water samples at Hamaca Hawk Missile Site.

2.9.3 Conclusions and Recommendations

Petroleum, battery acid, and lead were considered potential contaminants in surface water from Parcel A runoff. However, none of these were detected in excess of their action levels. Only a single inorganic, iron, was detected in excess of its action level. The noncarcinogenic human health risk posed by the detected concentration of iron in surface water at Hamaca Hawk Missile Site was not significant. Iron was the only chemical in surface water that exceeded ecological guidelines. Iron did not exceed ecological guidelines in sediment. Since no other chemicals exceeded guidelines in surface water, and since iron does not appear to be accumulating in sediment, iron in surface water probably does not pose potentially significant risks to ecological receptors. Therefore, due to the limited nature of contamination at subzone 10, no further action is recommended.

2.10 SUBZONE 11 (GROUNDWATER)

The subsections below describe subzone 11, present the contaminants detected, compare the detected concentrations with selected screening values, and provide conclusions on the SI findings for subzone 11 groundwater.

2.10.1 Subzone Description

Potential groundwater contaminant sources at Hamaca Hawk Missile Site included the storage and/or use of petroleum products, solvents, electrical batteries, lead, and electrical transformers. Subzone 11 includes groundwater from the entire Hamaca Hawk Missile Site area. Nine groundwater screening samples were collected to determine the location of three permanent wells installed during the SI field effort. These samples were analyzed for VOCs, SVOCs, and inorganics. Three permanent monitoring wells were installed and sampled. All of the analytical results can be found in Appendix D.

2.10.2 Site Investigation Findings

Contamination was investigated by analyzing groundwater in three monitoring wells installed at Hamaca Hawk Missile Site during the field effort for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the groundwater samples are listed in Table 2-9. Figure 2-9 shows the location of analytes that exceeded action levels and indicate possible groundwater contamination.

A single inorganic, arsenic, was detected in excess of its 50 µg/L action level at a single location (MW-04, 154 µg/L). Arsenic was not detected in either of the other two monitoring wells. Barium, iron, lead, and zinc were detected at subzone 11, but not in excess of their screening values. A single VOC, vinyl chloride, was detected in excess of its 1 µg/L screening value at MW-05 (8.6 µg/L), but not at the other monitoring well locations. Other VOCs detected below their screening values included 1,1-dichloroethane and 1,1-dichloroethene. No SVOCs were detected in groundwater at Hamaca Hawk Missile Site.

2.10.3 Conclusions and Recommendations

Petroleum products, solvents, electrical batteries, lead, and electrical transformers were considered to be potential sources of groundwater contamination at Hamaca Hawk Missile Site. Arsenic and vinyl chloride were detected in excess of their action levels in groundwater. Groundwater-to-surface-water migration of contaminants is possible at Parcel A, especially since groundwater at Key West is shallow. However,

ecological receptors are not directly exposed to groundwater, and no groundwater thresholds have been developed based on ecological concerns. Therefore, groundwater concentrations of analytes that exceeded action levels or had no action levels were compared to surface-water screening values (where applicable) as a conservative scenario (e.g., no attenuation or dilution) in accordance with EPA Region 4 (EPA 1995a) and FDEP (1996a) requirements. Arsenic was detected in four of the nine groundwater screening samples. With a single exception (GS-03), the highest detected value was 7.51 µg/L. The FDEP criteria for total arsenic in marine surface water is 50 µg/L (FDEP, 1996). A monitoring well was installed at the location of groundwater screening sample GS-03, and arsenic was detected in the resulting monitoring well sample (MW-04) at 154 µg/L, which is three times greater than the surface-water screening value. Arsenic was not detected in surface-water or sediment samples. Thus, migration of arsenic from MW-04/GS-03 sample location to surface water and sediment appears to be negligible.

Vinyl chloride was detected at 8.6 µg/L at MW-05. There are no EPA Region 4 nor FDEP ecological screening levels for this contaminant, but the detected concentration is well below the EPA Region 3 (EPA 1995b) screening level of 224,000 µg/L for marine surface water. In addition, vinyl chloride was not detected in any surface-water or sediment samples. Thus, migration of vinyl chloride from sample location MW-05 to surface water or sediment appears to be negligible and there is no evidence of ecological risks from vinyl chloride at Parcel A. Therefore, no further action is recommended for groundwater at the Hamaca Hawk Missile Site.

2.11 PARCEL A CONCLUSIONS AND RECOMMENDATIONS

Five soil subzones were included in the Hamaca Hawk Missile Site SI field investigation. Contaminants that may have resulted from various site and adjacent property uses and activities were considered. PAHs, solvents, battery acid, oils, dielectric fluid from vandalized Army transformers, and metals were potential contaminants identified during the DQO Process used to prepare the BRAC SI Workplan. Thallium was detected at all five soil subzones but exceeded its action level only at subzone 7. However, as discussed at the NAS Key West Partnering Team meeting in October 1998, thallium detections from SI sampling events are suspect and will not be used to drive further action. Arsenic and dibenzo(a,h)anthracene were detected in excess of their action levels in soil at subzone 1. The concentration of arsenic was not indicative of significant human health risks although the concentration of dibenzo(a,h)anthracene was indicative of potential carcinogenic human health risks. However, the dibenzo(a,h)anthracene detected was probably due to the storage of treated telephone poles in the area. No further action is recommended at subzone 1. There does not appear to be significant surface soil contamination at soil subzones 5, 6, and 7, and no further action is recommended at these subzones. At subzone 4, arsenic was also detected in excess of its action level at a concentration indicative of possible

human health risks. Further action is recommended at subzone 4. Removal of contaminated soils, is recommended at the sewage lift station.

Potential sediment and surface-water contaminant sources identified during the DQO process used to prepare the BRAC SI Workplan included the storage and/or use of petroleum products, solvents, electrical batteries, lead, hazardous waste, and pesticides. Several inorganics, including lead, were detected in excess of their action levels in sediment. Although none of these detections were at concentrations indicative of significant human health risks, further sampling may be needed to characterize potential ecological risks. A single inorganic, iron, was detected in excess of its action level in surface water. The maximum concentration of iron was not indicative of significant noncarcinogenic human health risks or ecological risks. Therefore, since there does not appear to be significant surface-water contamination at the Hamaca Hawk Missile Site Parcel. No further action is recommended.

There does not appear to be a complete migration pathway from the isolated detections of arsenic and vinyl chloride in groundwater to nearby surface water and sediment, and thus, ecological risks posed by these two analytes in groundwater appear to be insignificant and no further action is recommended for groundwater at Parcel A.

3.0 EAST MARTELLO BATTERY (PARCEL B)

3.1 PARCEL DESCRIPTION

The U.S. Army built East Martello Battery in the early 1940s for use as a Coastal Defense Battery. It was used as such until the property was transferred to the Navy in 1950 (Figure 3-1). The Navy developed the property in the early 1950s to accommodate 100 trailers to be used as housing. The trailer housing project also included two laundry facilities, but no dry cleaning operations were known to have been conducted. The trailer project was deactivated in 1956, and all trailers and buildings were removed from the site. Monroe County Civil Defense used the bunker from 1985 until 1992 as an administrative command post. The county has placed yard and tree cuttings on the property to dry prior to mulching and replacing.

The East Martello Battery Parcel is located on the western border of Key West International Airport, at the end of the runway. The airport stores and uses petroleum products. The Parcel is bounded on the north by old residential communities and on the south and west by saltwater ponds and undeveloped woodlands.

3.2 INVESTIGATION HISTORY

This section describes previous and current investigations for the East Martello Battery Parcel.

3.2.1 Previous Investigations

Existing documents include the USN-NPWC Lead and Asbestos Survey of East Martello Battery (USN-NPWC, 1995b) and the USN-SUPSHIP Predraft EBS Realignment Parcels (USN-SUPSHIP, 1996). No previous soil or groundwater analytical data exist. Based on the 1995 inspection performed by the NPWC, both LBP and suspected ACBMs are present in East Martello Battery facilities and infrastructure.

The EBS (USN-SUPSHIP, 1996) documented a number of factors that are potentially helpful in characterizing the site:

- Although the storage of hazardous or petroleum substances at the site in the past has been documented, no visible sheen or discoloration of surface water has been observed.

- No stains were observed on site soils, although old stains of an indeterminate nature were found on the floors of several site facilities.
- A freshwater tower and tank were previously located at the site but have been removed.
- Concrete freshwater storage and sewage dosing tanks are in the northeast and northwest corners of Parcel B but appear to have been out of service for many years.
- A septic drain field is on the southwest portion of the property, but it has not been used since the 1950s, when the sanitary waste dosing station ceased operation.
- There is no reason to suspect PCB contamination at this facility.
- Although pesticides are commonly used for mosquito and pest control throughout NAS Key West, there is no evidence of pesticide misuse at the site.

3.2.2 Current Investigation

The DQO Process evaluated three subzones for the East Martello Battery Parcel. Subzone 2 was eliminated from further consideration. It was assumed that the septic field located on the site would be addressed in the groundwater assessment of subzone 3 which includes the same area. Two subzones within Parcel B required sampling and analysis under the BRAC SI. The environmental medium of each subzone and the parameter groups selected for analysis at each subzone, are presented in Table 3-1. The four soil sample locations in subzone 1 (East Martello Battery) are shown in Figure 3-2, while the placement of three permanent monitoring wells that were sampled in subzone 3 is shown in Figure 3-3. Analytical results for samples collected at Parcel B were compared to an industrial set of action levels (see Section 1.8.2.1).

3.3 SUBZONE 1 (EAST MARTELLO BATTERY)

The subsections below describe subzone 1, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 1 surface soil.

3.3.1 Subzone Description

Petroleum, solvents, fuels, and lead were considered potential soil contaminants in subzone 1. Four surface soil samples were collected. All of the analytical results can be found in Appendix D.

3.3.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in subzone 1 for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 3-2. Figure 3-2 shows the sample locations of all surface soil samples collected at subzone 1.

No VOCs were detected in excess of their action levels. VOCs detected below their screening criteria included 2-butanone, 2-hexanone, acetone, chlorobenzene, chloromethane, ethylbenzene, toluene, and xylenes. No SVOCs or inorganics were detected in excess of their action levels. SVOCs detected in surface soil at subzone 1 but not in excess of action levels included 1,2-dichlorobenzene, 1,3-dichlorobenzene, 1,4-dichlorobenzene, benzo(k)fluoranthene, bis(2-ethylhexyl)phthalate, and butyl benzyl phthalate. Inorganics detected below their action levels included aluminum, antimony, arsenic, barium, cadmium, chromium, copper, iron, lead, manganese, mercury, nickel, tin, vanadium, and zinc.

3.3.3 Conclusions and Recommendations

Petroleum, solvents, fuels, and lead from past uses as a defense battery were considered to be potential surface soil contaminants. However, no chemicals were detected in excess of action levels. Therefore, there does not appear to be significant contamination in the surface soil at subzone 1 and no further action is recommended.

3.4 SUBZONE 3 (GROUNDWATER)

The subsections below describe subzone 3, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 3 groundwater.

3.4.1 Subzone Description

Solvents, fuels, and lead from past use as a defense battery and trailer park were considered to be potential groundwater contaminants at East Martello Battery. Subzone 3 includes groundwater under the East Martello Battery Parcel. Nine groundwater screening samples were collected in subzone 3 for use in determining the location of three permanent wells installed during the SI field effort. These samples were analyzed for VOCs, SVOCs, and inorganics. All of the results can be found in Appendix D. Three permanent monitoring wells were installed during the field effort: one in the northern portion of the site

near some ponds, one in the center of the site to the east of the battery, one west of the battery and road. Samples were taken from these wells during the SI. All of the analytical results can be found in Appendix D.

3.4.2 Site Investigation Findings

Contamination was investigated by analyzing groundwater in three monitoring wells installed at East Martello Battery for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the groundwater samples are listed in Table 3-3. Figure 3-3 shows the locations of all monitoring wells sampled at subzone 3.

No VOCs, SVOCs, or inorganics were detected in excess of their screening values in groundwater at subzone 3. Iron, lead, and zinc were the only chemicals detected in groundwater monitoring well samples from East Martello Battery.

3.4.3 Conclusions and Recommendations

Solvents, fuels, and lead from past uses as a defense battery and trailer park were considered to be potential contaminant sources in groundwater at Parcel B. However, no chemicals were detected in excess of action levels. Therefore, there does not appear to be significant contamination in the groundwater in East Martello Battery and no further action is recommended.

3.5 PARCEL B CONCLUSIONS AND RECOMMENDATIONS

The Base Reuse Plan (BAP, 1997) proposes a combination of zoning categories for East Martello Battery including Public and Semi-Private Services (PS) and two Conservation districts: Outstanding Florida Waters (C-OW) and Tidal Wetlands of the State (C-TW). The majority of the East Martello Battery site is proposed for use by the Key West International Airport as a runway clear zone and obstruction-free zone; the remainder of the site is proposed for preservation and passive open space recreation (nature trails, scenic overlooks, etc.).

Petroleum, solvents, fuels, and lead were identified as potential contaminants at the East Martello Battery Parcel during the DQO Process. Petroleum, solvents, fuels, and lead were not detected in surface soil or groundwater in excess of their action levels. Therefore, it does not appear that there is significant soil or groundwater contamination at East Martello Battery and no further action is recommended.

TABLE 3-1

**PARAMETER GROUPS AND MEDIA OF INTEREST AT EAST MARTELLO BATTERY (PARCEL B)
NAS KEY WEST**

Subzone	Building/Area	Medium	Number of Locations	Parameter Group				
				VOCs	SVOCs	Inorganics	PCBs	Pesticides
Subzone 1	East Martello Battery	SO	4	X	X	X		
Subzone 3	Groundwater	GW	3	X	X	X		

SO = Surface soil.
GW = Groundwater.

Subzone 2 was eliminated from sampling during the DQO Process.

4.0 TRUMAN ANNEX DRMO WASTE STORAGE AREA (PARCEL C)

4.1 PARCEL DESCRIPTION

The DRMO Waste Storage Area includes Buildings 795, 284, and 261 and two large fenced storage areas (Figure 4-1). The DRMO receives excess government materials. In the recent past, Building 261 stored hazardous materials and Building 795 stored inert materials. A cleared area in front of Building 795, known as IR 2, has been investigated for PCB contamination under the Navy's Installation Restoration (IR) Program. The PCBs were the result of PCB-contaminated oil used for dust suppression in the area. The investigation recommended no further action for the site based on sampling and risk assessment results. The two large storage areas primarily stored metal debris. In addition, motors, vehicles, boats, refugee debris, and fuel trucks have been stored in those areas. Currently, metal debris including some machinery with motors is present in one of the storage areas (B&R Environmental, 1997b). A review of maps from the 1940s and 1950s also indicated the presence of oil racks within the other storage area.

4.2 INVESTIGATION HISTORY

This section describes previous and current investigations for the Truman Annex DRMO Waste Storage Area.

4.2.1 Previous Investigations

Existing documents include the USN-NPWC Lead and Asbestos Survey of Truman Pier (USN-NPWC, 1996) and USN-NFEC NAS Key West Predraft EBS Truman Annex; Excess Property (USN-NFEC, 1996a). No previous soil or groundwater analytical data exist.

4.2.2 Current Investigation

The DQO Process evaluated five subzones of the DRMO Waste Storage Area Parcel. Subzones 2 and 5 were eliminated from further consideration. Three subzones within Parcel C required sampling and analysis under the BRAC SI. The environmental medium of each subzone and the parameter groups selected for analysis in each subzone are presented in Table 4-1. Subzone 1 (Building 261 Hazardous Material Storage [Former DRMO]), subzone 3 (Former Oil Container [Pre-1942] and Scrap Metal and Refugee Item Storage Areas), and subzone 4 (Former Scrap Metal Storage Area [Former DRMO]) were identified as soil subzones, and the four sample locations in each subzone are shown on Figures 4-2

through 4-4. Analytical results for samples collected at Parcel C were compared to a residential set of action levels (see Section 1.8.2.1).

Although the BRAC SI Workplan (B&R Environmental, 1998a) describes five groundwater subzones at Truman Annex, one at each Parcel (i.e., C, D, E, F, and K), the DQO Process considered the groundwater at Truman Annex as a single unit in the decision-making process. Discussion of sampling and analytical results for groundwater at Truman Annex (including Parcels C, D, E, F, and K) are included in Section 4.6. The locations of four permanent monitoring wells and a single previously existing monitoring well at Truman Annex are shown in Figure 4-5.

4.3 SUBZONE 1 (BUILDING 261 HAZARDOUS MATERIAL STORAGE)

The subsections below describe subzone 1, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 1 surface soil.

4.3.1 Subzone Description

Solvents, fuels, and pesticides were considered potential soil contaminants in subzone 1 from past waste storage activities at Building 261. Four surface soil samples were collected around Building 261. All of the analytical results can be found in Appendix D.

4.3.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in subzone 1 for VOCs, SVOCs, pesticides, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.2 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 4-2. Figure 4-2 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

Two inorganics, lead and thallium, were detected in excess of their screening criteria. Lead was detected in excess of its 500 mg/kg action level at a single soil sample location (SS-01; 978 mg/kg). Thallium was detected at three of the four soil samples at Building 261, but was an exceedance only at SS-02 (5.5 mg/kg). Other inorganics detected, but not in excess of their action levels included aluminum, barium, cadmium, chromium, copper, iron, manganese, mercury, nickel, selenium, vanadium, and zinc.

Aroclor-1260, a PCB, was detected in a single soil sample (SS-04, 2,700 µg/kg) and was in excess of its 900 µg/kg residential soil action level. One SVOC, benzo(a)pyrene, was detected in excess of its 100 µg/kg screening value at two of the four soil sample locations (SS-01, 478 µg/kg; SS-03, 189 µg/kg). Other SVOCs detected below their screening criteria included benzo(a)anthracene, benzo(b)fluoranthene, chrysene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, and pyrene. No pesticides were detected in excess of their screening values. Pesticides detected in soil at Building 261 included 4,4'-DDD, 4,4'-DDE, 4,4'-DDT, and alpha-BHC.

4.3.3 Conclusions and Recommendations

Petroleum, solvents, fuels, and lead from past hazardous material storage were considered to be potential surface soil contaminants in subzone 1. Chemicals that were detected in excess of their action levels were analyzed further in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates for subzone 1 can be found in Appendix C, Table C-3. Lead and thallium were considered as exceedances. The maximum lead detection is indicative of possible human health risks. SI thallium results are suspect and will not be used to drive further action. Therefore, although thallium does not pose a significant human health risk in subzone 1 soil, but lead may. The benzo(a)pyrene concentration was not indicative of significant carcinogenic human health risk. Aroclor-1260 concentration was indicative of possible carcinogenic human health risks. Therefore, due to the contamination at subzone 1, further action is recommended.

4.4 SUBZONE 3 [FORMER OIL CONTAINER (PRE-1942) AND SCRAP METAL AND REFUGEE ITEM STORAGE AREAS]

The subsections below describe subzone 3, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 3 surface soil.

4.4.1 Subzone Description

Fuels, oil, and metal were considered potential soil contaminants at subzone 3 from past oil and metal storage activities in the former oil container and scrap metal and refugee item storage areas. During the DQO Process, four sample locations were chosen in subzone 3. After further consideration, the NAS Key West Partnering Team decided to add four more sample locations based on the sensitive reuses proposed for the area. Eight surface soil samples were collected during the SI field effort around the storage area. All of the analytical results can be found in Appendix D.

4.4.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in subzone 3 for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 4-3. Figure 4-3 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

A single SVOC, benzo(a)pyrene, was detected in excess of its 100 µg/kg action level in a single sample (SS-01; 180 µg/kg). This detection was near the center of the subzone and at the southeastern corner of the parking lot. Benzo(a)pyrene was detected at four out of the seven other sample locations. Antimony, lead, and thallium were the only inorganics detected in excess of their action levels. Antimony was detected in excess of its action level at one sample location (SS-06, 41.1 mg/kg) and below its action level at two sample locations. Lead was detected at all eight sample locations but was in excess of its action level only at SS-06 (2,110 mg/kg) and SS-08 (1,840 mg/kg). Thallium was detected at all eight soil samples and was considered as an exceedance at three of these locations. Thallium concentrations ranged from 4 mg/kg to 6.05 mg/kg. No VOCs were detected in excess of their screening values. A number of chemicals were detected at levels below their action levels. VOCs detected, but not in excess of their action levels, included acetone, toluene, and xylenes. 1,2,4-trichlorobenzene, acenaphthylene, anthracene, benzo(b)fluoranthene, benzo(g,h,i) perylene, benzo(k)fluoranthene, fluoranthene, indeno(1,2,3-cd)pyrene, and pyrene were the SVOCs detected below their screening values in surface soil at subzone 3. Inorganics detected at concentrations less than their action levels included aluminum, arsenic, barium, cadmium, chromium, cobalt, copper, iron, manganese, nickel, silver, vanadium, and zinc.

4.4.3 Conclusions and Recommendations

Fuels, oil, and metal from past uses as oil container and scrap metal and refugee item storage areas were considered to be potential surface soil contaminants at subzone 3. Estimated risks were calculated for chemicals detected in excess of their action levels as described in Section 1.8.2.1. Calculations and estimates can be found in Appendix C, Table C-1. Lead, thallium, and antimony detections in surface soil exceeded action levels. As a result, a permanent monitoring well was installed in this subzone during the SI field effort. Noncarcinogenic risks may be posed by antimony detected in soil at subzone 3. The maximum lead concentration was indicative of potential human health risks. The maximum detection of thallium also was indicative of potential noncarcinogenic human health risks but will not drive further action, as discussed in Section 1.8.2.1. Benzo(a)pyrene was detected in excess of its action level and

may be indicative of potential carcinogenic human health risks. Therefore, due to the nature of contamination at subzone 3, further action is recommended.

4.5 SUBZONE 4 [FORMER SCRAP METAL STORAGE AREA (FORMER DRMO)]

The subsections below describe subzone 4, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 4 surface soil.

4.5.1 Subzone Description

Subzone 4 was considered to contain potential metal contaminants from its past metal storage activities. During the DQO Process, four soil samples were sited in subzone 4. However, due to the sensitive nature of reuses proposed for this area, the NAS Key West Partnering Team requested that four additional samples be located in subzone 4. Eight surface soil samples were collected from in and around the miscellaneous scrap metal pile and storage area. All of the analytical results can be found in Appendix D.

4.5.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in this subzone for VOCs, SVOCs, and inorganics. (Sample SS-03 was inadvertently not tested for VOCs.) The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 4-4. Figure 4-4 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

A single SVOC, benzo(a)pyrene, was detected in excess of its 100 µg/kg action level in two samples. One of these detections was at the fence on the north side of the subzone (SS-02, 394 µg/kg). The second was at the eastern fence boundary of the subzone (SS-07, 532.5 µg/kg). Benzo(a)pyrene was not detected at any of the other six samples. Antimony (93.5 mg/kg) and lead (7,690 mg/kg) were detected in excess of their screening criteria, 26 mg/kg and 500 mg/kg, respectively, at SS-06. This was the only detection of antimony in subzone 4; however, lead was detected in all eight samples. Thallium was detected in all eight soil samples, but was an exceedance at only one location (SS-01, 10 mg/kg). No VOCs were detected in excess of their action levels; however acetone, ethylbenzene, methylene chloride, and toluene were detected in subzone 4 soil samples. A number of SVOCs were detected below their action levels including benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene,

benzo(k)fluoranthene, chrysene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, and pyrene. Inorganics detected at concentrations less than their screening criteria included aluminum, barium, cadmium, chromium, copper, iron, manganese, mercury, nickel, selenium, tin, vanadium, and zinc.

4.5.3 Conclusions and Recommendations

Metal from past uses was considered a potential source for surface soil contamination in the former scrap metal storage area. Estimated risks were calculated for chemicals detected in excess of their action levels as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-1. Lead was detected in surface soil in excess of its action level. A new permanent monitoring well was installed at SS-02. The estimated noncarcinogenic risks for antimony were indicative of possible human health risks. The maximum lead concentration also was indicative of possible human health risks. The maximum thallium detection was indicative of potential noncarcinogenic human health risks, but thallium results are suspect and will not be used to drive further action. Benzo(a)pyrene was detected in excess of its action level and had an estimated carcinogenic risk indicative of potential human health risks. Therefore, due to the nature of contamination at subzone 4, further action is recommended.

4.6 TRUMAN ANNEX GROUNDWATER

The subsections below describe groundwater at Truman Annex, present the contaminants detected, compare the detected concentrations with selected screening values, and provide conclusions on the SI findings for groundwater at Truman Annex.

4.6.1 Subzone Description

Fuels, oils, metals, and solvents were considered potential groundwater contaminants at Truman Annex. Nine groundwater screening samples were collected in Parcels C, E, F, and K. Four groundwater screening samples were collected in Parcel D. These groundwater screening samples were used in determining the location of permanent wells installed during the SI field effort. These groundwater samples were analyzed for VOCs, SVOCs, and inorganics. All of the results can be found in Appendix D. Two permanent monitoring wells were installed near the scrap metal pile area and the water tower at Parcel C during the SI field effort. A permanent monitoring well was installed at both Parcels K and F. Samples were taken from these wells during the SI. An existing monitoring well also was sampled in Parcel E. All of the analytical results can be found in Appendix D.

4.6.2 Site Investigation Findings

Contamination was investigated by analyzing groundwater in five monitoring wells at Truman Annex during the field effort for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the groundwater samples are listed in Table 4-5. Figure 4-5 shows the location of analytes that exceeded action levels and indicate possible groundwater contamination.

A single SVOC, phenanthrene, and a single VOC, benzene, were detected in excess of their screening criteria. Both were detected at a single sample location, K05-MW-01. Other SVOCs detected but not in excess of their action levels included 2,4-dimethylphenol, 3,4-methylphenol, 2-methylnaphthalene, acenaphthene, anthracene, dibenzofuran, fluoranthene, fluorene, naphthalene, and pyrene. Other VOCs detected at levels below their screening criteria included 2-butanone, 2-hexanone, ethylbenzene, toluene, and xylene. Iron, lead, manganese, and zinc were detected at concentrations lower than their screening values in groundwater at Truman Annex.

4.6.3 Conclusions and Recommendations

Fuels, oils, metals, and solvents were considered to be potential sources of contamination in the groundwater at Truman Annex. One SVOC and one VOC were considered as exceedances. Groundwater-to-surface water migration of groundwater contaminants is possible at NAS Key West, because the groundwater on the station is shallow. However, ecological receptors are not directly exposed to groundwater, and no groundwater thresholds have been developed based on ecological concerns. Therefore, groundwater concentrations of analytes that exceeded action levels or had no action levels were compared to surface-water screening values (where applicable) as a conservative scenario (e.g., no attenuation or dilution) in accordance with EPA Region 4 (EPA, 1995a) and FDEP (FDEP, 1996a) requirements. 2-methylnaphthalene was detected in K05-MW-01 at 262 µg/L. There are no EPA Region 4 or FDEP ecological screening levels for this contaminant, but the EPA Region 3 BTAG screening level (EPA, 1995b) is 300 µg/L in marine surface water. Thus, ecological risks from 2-methylnaphthalene in groundwater are insignificant. Benzene was detected above its action level in Truman Annex groundwater (K05-MW-01). However, the benzene concentration is well below ecological screening values from both FDEP and EPA. There is no evidence of ecological risks from benzene in groundwater. The detection of phenanthrene at K05-MW-01 (187 µg/L) is substantially higher than the 8.3 µg/L screening level in marine surface water (EPA, 1996b). However, phenanthrene was only detected in one well and was not detected in any screening samples taken between K05-MW-01 and nearby surface water bodies. Based on the lack of detection, phenanthrene does not seem to be

migrating to surface water. Therefore, because of phenanthrene was only detected in one well and is not migrating to surface water, the potential for risks to ecological receptors appears to be negligible. Ecological risks for phenanthrene and benzene in Truman Annex groundwater are estimated in Appendix C. No further action is recommended for Truman Annex groundwater except at Parcel E in the vicinity of Buildings 102, 103, and 104 (Parcel E, subzone 7).

4.7 PARCEL C AND TRUMAN ANNEX GROUNDWATER CONCLUSIONS AND RECOMMENDATIONS

Fuels, oils, metals, and solvents from past metal waste storage activities were considered potential sources of contamination in the DRMO Waste Storage Area during the DQO Process. Lead and thallium were considered exceedances in all three soil subzones of the Parcel. However, thallium detections will not be used to drive further action in the SI, as described in Section 1.8.2.1. Antimony also was detected in excess of its action level in soil subzones 3 and 4. The maximum detections of antimony and lead were indicative of potential human health risks in subzones 3 and 4. Subzone 1 soil exceedances of lead and subzone 3 and 4 exceedances of antimony, lead, and thallium pose potential human health risks. Benzo(a)pyrene in subzones 3 and 4 and aroclor-1260 detections in subzone 1 were at concentrations indicative of potential carcinogenic human health risks. Therefore, further action is recommended to address soil contamination at Parcel C and the potential risks posed by these contaminants. An interim remedial action at subzones 1, 3, and 4 is recommended to remove contaminated soils.

Phenanthrene and benzene were exceedances in groundwater at Truman Annex. The detection of phenanthrene was well above its EPA marine surface-water screening level and may pose a risk to environmental receptors. The detections of phenanthrene and benzene were limited to K05-MW-01. Potential ecological risks from phenanthrene and benzene are negligible; however, risks are estimated to be negligible due to the lack of chemical detections in groundwater screening samples collected in the vicinity of K05-MW-01.

**TABLE 4-1
PARAMETER GROUPS AND MEDIA OF INTEREST AT TRUMAN ANNEX
DRMO WASTE STORAGE AREA (PARCEL C)
NAS KEY WEST**

Subzone	Building/Area	Medium	Number of Locations	Parameter Group				
				VOCs	SVOCs	Inorganics	PCBs	Pesticides
Subzone 1	Building 261 Hazardous Material Storage (Former DRMO)	SO	4 ^(a)	X	X	X		X
Subzone 3	Former Oil Container (Pre-1942) and Scrap Metal and Refugee Item Storage Areas	SO	8	X	X	X		
Subzone 4	Former Scrap Metal Storage Area (Former DRMO)	SO	8 ^(b)	X	X	X		

Notes:

- a A single sample taken at one of these locations was initially not submitted for SVOC and metals analysis. The location was resampled and a sample was resubmitted for these fractions during the February 1998 field effort.
- b A sample taken at one of these locations was inadvertently not tested for VOCs.

SO = Surface soil.

Subzones 2 and 5 were eliminated from sampling during the DQO Process.

5.0 TRUMAN ANNEX SEMINOLE BATTERY (PARCEL D)

5.1 PARCEL DESCRIPTION

Parcel D (Figure 5-1) includes the Seminole Battery and an adjacent area known to include a former fueling area and grease rack that operated in the 1940s and 1950s (B&R Environmental, 1996). The battery was constructed during the Civil War; a modern battery addition was added similar in construction to the East Martello Battery in the 1950s. Both structures are currently unused, and entry is restricted. The materials used while the batteries were in operation are unknown. The oldest portion of the battery has the remnants of a generator exhaust system.

The former fueling area known as 248 Tanks A&B is located west of Seminole Battery. The fueling island and the tanks were removed in August 1995. The area is now covered in asphalt. The UST Closure Report (OES, 1995) recommended a study of groundwater in the area. To the northeast of the former tank location, concrete slabs are present from former grease racks used to lubricate and service vehicles. No visible stains are present on or near the slabs (B&R Environmental, 1996).

5.2 INVESTIGATION HISTORY

This section describes previous and current investigations for the Truman Annex Seminole Battery Parcel.

5.2.1 Previous Investigations

Existing documents include the UST Closure Report (OES, 1995) that details the closure of Tanks 248A and 248B formerly located at the gas station, and the Army dispensing facility at Seminole Battery (subzone 4). Soil screening samples and groundwater samples were collected and analyzed during the closure. The closure report concluded that the tanks were closed in accordance with Florida guidelines.

5.2.2 Current Investigation

The DQO Process evaluated three subzones for the Seminole Battery Parcel. Subzone 4 was eliminated from further consideration. Two subzones within Parcel D required sampling and analysis under the BRAC SI. The environmental medium of each subzone and the parameter groups selected for analysis at each subzone, are presented in Table 5-1. The random placement of four soil sample locations in

subzone 1 (Seminole Battery) and subzone 2 (Former Grease Racks) are shown in Figures 5-2 and 5-3, respectively. Analytical results for samples collected at Parcel D were compared to a residential set of action levels (see Section 1.8.2.1).

Although the BRAC SI Workplan (B&R Environmental, 1998a) describes five groundwater subzones at Truman Annex, one at each Parcel (i.e., C, D, E, F, and K), the DQO Process considered the groundwater at Truman Annex as a single unit in the decision-making process. Discussion of sampling and analytical results for groundwater at Truman Annex (including Parcels C, D, E, F, and K) is included in Section 4.6. The locations of four permanent monitoring wells and a single previously existing monitoring well at Truman Annex are shown in Figure 4-5.

5.3 SUBZONE 1 (SEMINOLE BATTERY)

The subsections below describe subzone 1, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 1 surface soil.

5.3.1 Subzone Description

Used oils, cleaning agents, solvents, fuel, and metals were considered to be potential contaminants at Seminole Battery from past activities including storage of hazardous materials and vehicles. Four surface soil samples were collected from near the entrances to the battery. All of the analytical results can be found in Appendix D.

5.3.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in Seminole Battery for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 5-2. Figure 5-2 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

A single inorganic, arsenic, was detected at its 2.7 mg/kg action level at a single sample, SS-03. Two SVOCs also were detected at SS-03 in excess of their screening values. Benzo(a)pyrene (505 µg/kg) and benzo(b)fluoranthene (1,900 µg/kg) were detected in excess of their 100 µg/kg and 1,400 µg/kg

action levels, respectively. Benzo(a)pyrene also was detected at SS-01 and benzo(b)fluoranthene also was detected at the three other sample locations, but not in excess of their action levels. No VOCs were detected in excess of their action levels. A single detection of methylene chloride was the only VOC detected at subzone 1. Benzo(g,h,i)perylene, chrysene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, and pyrene were the SVOCs detected at levels below their screening criteria. Inorganics that were detected but did not exceed the action levels included aluminum, antimony, barium, chromium, copper, iron, lead, manganese, mercury, vanadium, and zinc.

5.3.3 Conclusions

Potential contaminants at subzone 1 included used oils, cleaning agents, solvents, fuel, and metals from past activities including storage of hazardous materials and vehicles. Arsenic was detected at its 2.7 mg/kg action level at a single soil sample location. Benzo(a)pyrene and benzo(b)fluoranthene were the only SVOCs detected in excess of their action levels in surface soil at subzone 1. The maximum detections of benzo(a)pyrene and benzo(b)fluoranthene were used in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-2. Although neither benzo(a)pyrene nor benzo(b)fluoranthene pose potential carcinogenic risk to humans at the detected concentrations, further action is recommended around the sample location (DO1-SS-03) where all exceedances occurred.

5.4 SUBZONE 2 (FORMER GREASE RACKS)

The subsections below describe subzone 2, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 2 surface soil.

5.4.1 Subzone Description

Lubricants and grease were considered to be potential contaminations at the former grease racks in subzone 2. Four surface soil samples were collected, one from each side of the racks. All of the analytical results can be found in Appendix D.

5.4.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the vicinity of the former grease racks for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in

Section 1.8.1.2 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 5-3. Figure 5-3 shows the sample locations of all surface soil samples collected at subzone 1.

No VOCs, SVOCs, or inorganics were detected in excess of action levels in surface soil at the former grease racks area. No VOCs were detected. SVOCs were detected at levels below their screening criteria including benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, chrysene, fluoranthene, indeno(1,2,3-cd)pyrene, and pyrene. Inorganics were detected at concentrations below their action levels including aluminum, arsenic, barium, chromium, copper, iron, lead, manganese, mercury, vanadium, and zinc.

5.4.3 Conclusions

Lubricants and grease were considered to be potential soil contaminants in the former grease racks area. However, no chemicals were detected in excess of action levels. Therefore, there does not appear to be significant contamination in the surface soil at the former grease racks and no further action is recommended.

5.5 PARCEL D CONCLUSIONS AND RECOMMENDATIONS

Lubricants, grease, oils, cleaning agents, solvents, fuel, and metals were identified as potential contaminants during the DQO Process utilized to prepare the BRAC SI Workplan. These sources of contamination were considered as potential contaminants from past activities including storage of hazardous materials and vehicles at Seminole Battery. No chemicals were detected in excess of their action levels at subzone 2, the former grease racks. However, arsenic, benzo(a)pyrene, and benzo(b)fluoranthene were detected in excess of their action levels at a single soil sample location (SS-03) in the eastern portion of subzone 1. Further action is recommended at subzone 1 around soil sampling location DOI-SS-03.

6.0 TRUMAN ANNEX BUILDINGS 102, 103, AND 104 (PARCEL E)

6.1 PARCEL DESCRIPTION

Parcel E (Figure 6-1) includes the area known as the Inner Mole Pier. The area has served as a naval docking and support facility for more than a century. Most records of the area date to the period of World War II. In the late 1980s, the Inner Mole Pier waterfront was refurbished along with the Outer Mole Pier (Parcel K).

Building 102 (Former Torpedo Overhaul and Storehouse), Building 103 (Former Central Power Plant), and Building 104 (Former Battery Overhaul and Storage) are still standing but are out of service. Knowledge of the operations in these buildings is limited to naval submarine support activities. Hazardous materials, specifically VOCs, SVOCs, and inorganics, are believed to have been used in each of the buildings. PCBs are known to have been present in transformers at Building 103. In the mid 1980s, these transformers were removed from the building. A petroleum Contamination Assessment Report (CAR) was prepared for the area around the three buildings. The CAR recommended the preparation of a Remedial Action Plan (RAP) that was approved in April 1995 by FDEP (USN-NFEC, 1992a, 1993a).

Building 189 (former Liquor Store) is adjacent to an area affected by a petroleum leak from an underground pipeline that serviced the docks. The pipeline enters the Parcel from Eaton Street and runs along the waterfront across Parcel E and Parcel K ending on Outer Mole Pier. A petroleum CAR was prepared for the area north of Building 189. The CAR recommended the preparation of a RAP that was approved in November 1995 by FDEP (USN-NFEC, 1992b, 1993b).

Former Building 136 (Shipfitters and prior to 1951 the Plate and Mold Shop) was demolished and the debris was buried in and around the building's footprint. According to base personnel, the debris in the area was later removed for disposal and is known to have failed Toxicity Characteristic Leaching Procedure (TCLP) testing for lead. The area around the former Building 136 is currently level graded limestone. Buildings in the Parcel that have been razed include the following:

- 26 - Cistern (distilled water)
- 59 - Storehouse
- 60 - Boiler Shop
- 79 - Electrical Shop

- 100 - Cold Storage
- 101 - Submarine General Shops and Offices
- 115 - Diesel Oil Storage Tank
- 116 - Steam Plant
- 117 - Fuel Oil Storage
- 118 - Battery Water Storage Tank
- 122 - Fire Station
- 123 - Public Works Maintenance Office, Garage, and Shops
- 136 - Shipfitters/former Plate and Mold Shop (pre-1951)
- 147 - Sound School Shop and Laboratory
- 148 - Fresh Water Tank
- 156 - Submarine Storage Shed
- 157 - Equipment Shed
- 160 - Ordnance Warehouse/former Anti-Aircraft Trainer (pre-1951)
- 168 - Storage Building
- 169 - General Storage
- 171 - Storehouse
- 172 - Women Accepted for Volunteer Emergency Service (WAVES) Officers' Quarters
- 173 - WAVES Officers' Quarters
- 174 - Cistern

6.2 INVESTIGATION HISTORY

This section describes previous and current investigations for the Truman Annex Buildings 102, 103, and 104 Parcel.

6.2.1 Previous Investigations

Existing documents include the USN-NFEC NAS Key West Predraft EBS Truman Annex; Excess Property (USN-NFEC, 1996a) and USN-NFEC Draft EBS Truman Annex Outer Mole Pier 8/Buildings 149, 1374, 4080 (USN-NFEC, 1997). Also the USN-NFEC Contamination Assessment Report (CAR) Addendum for Electric Power Plant Building 103 (USN-NFEC, 1993a), the USN-NFEC Contamination Assessment Report (CAR) for Electric Power Plant Building 103 (USN-NFEC, 1992a), and the USN-NFEC Remedial Action Plan (RAP) for Electric Power Plant Building 103 (USN-NFEC, 1994a).

6.2.2 Current Investigation

The DQO Process evaluated 10 subzones for Parcel E. Subzones 6, 8, 10, and 11 were eliminated from further evaluation. Six subzones required sampling and analysis under the BRAC SI. The environmental medium of each subzone and the parameter groups selected for analysis at each subzone, are presented in Table 6-1. Subzone 1 (Former Building Sites South End of Parcel E), subzone 2 (Former Building 136), subzone 3 (Buildings 102 and 104), subzone 4 (Transformer Site near Building 675), subzone 5 (Former Building Sites North End of Parcel E), and subzone 9 (Building 103) were identified as soil subzones. Four locations were sampled within each subzone, except six sample locations were placed in subzone 3. Sample locations are shown on Figures 6-2 through 6-7. Analytical results for samples collected at Parcel E were compared to a residential set of action levels (see Section 1.8.2.1).

Although the BRAC SI Workplan (B&R Environmental, 1998a) describes five groundwater subzones at Truman Annex, one at each Parcel (i.e., C, D, E, F, and K), the DQO Process considered the groundwater at Truman Annex as a single unit in the decision-making process. Discussion of sampling and analytical results for groundwater at Truman Annex (including Parcels C, D, E, F, and K) are included in Section 4.6. The location of four permanent monitoring wells and a single previously existing monitoring well at Truman Annex are shown in Figure 4-5.

6.3 SUBZONE 1 (FORMER BUILDING SITES SOUTH END OF PARCEL E)

The subsections below describe subzone 1, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 1 surface soil.

6.3.1 Subzone Description

Metals, solvents, and fuels from former building operations and demolition debris were considered as potential contaminants at the former building sites at the south end of Parcel E. Four surface soil samples were collected. All of the analytical results can be found in Appendix D.

6.3.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the vicinity of the former building sites at the south end of Parcel E for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies

and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 6-2. Figure 6-2 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

Thallium was detected at all four sample locations in excess of its 5.5 mg/kg action level. However, it has been determined that the thallium results from the SI are suspect and will not be used to drive further action. Inorganics detected at concentrations below their action levels including aluminum, barium, cobalt, copper, iron, lead, manganese, mercury, vanadium, and zinc. No VOCs or SVOCs were detected in excess of action levels in surface soil at the former building sites at the south end of Parcel E. Acetone was the only VOC detected in subzone 1. SVOCs detected at levels below their screening criteria including benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, bis(2-ethylhexyl)phthalate, fluoranthene, indeno(1,2,3-cd)pyrene, and pyrene.

6.3.3 Conclusions and Recommendations

Metals, solvents, and fuels from former building operations and demolition debris were considered as potential contaminants at the former building sites at the south end of Parcel E. However, thallium was the only exceedance. The maximum detection of thallium was used in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-2. Although the maximum thallium concentration detected was indicative of potential noncarcinogenic human health risks, the thallium results are suspect and will not be used to drive further action. No other chemicals were detected in excess of their action levels. No further action is recommended at subzone 1.

6.4 SUBZONE 2 (FORMER BUILDING 136)

The subsections below describe subzone 2, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 2 surface soil.

6.4.1 Subzone Description

Debris, lead, metals, solvents, and oils were considered potential soil contaminants at subzone 2 from building operations including the Plate and Mold Shop and the demolished Building 136 buried on-site. Four surface soil samples were collected from the former location of Building 136. All of the analytical results can be found in Appendix D.

6.4.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the former location of Building 136 for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 6-3. Figure 6-3 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

Two inorganics, arsenic and thallium, exceeded their surface soil action levels. The arsenic exceedance (4.5 mg/kg) was in a single sample (SS-02) collected from the eastern corner of subzone 2. Arsenic was detected at one other surface soil sample location, but not in excess of its action level. Thallium was detected at all four sample locations, but was an exceedance only at SS-02 (6.2 mg/kg). Three SVOCs also were detected in excess of their screening values. Benzo(a)pyrene was detected in excess of its 100 µg/kg screening value at SS-02 (988 µg/kg) and SS-01 (225 µg/kg). Benzo(b)fluoranthene and indeno(1,2,3-cd)pyrene were both detected at SS-02 in excess of their action levels. SVOCs detected at concentrations below their screening criteria included acenaphthylene, anthracene, benzo(a)anthracene, benzo(g,h,i)perylene, fluoranthene, fluorene, and pyrene. VOCs detected included acetone, methylene chloride, and toluene – none above their action levels. Several inorganics were detected below their action levels including aluminum, antimony, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, vanadium, and zinc.

6.4.3 Conclusions and Recommendations

Potential contaminants in soil from building operations at the Plate and Mold Shop and demolished Building 136 buried on-site included debris, lead, metals, solvents, and oils. Arsenic, thallium, benzo(a)pyrene, benzo(b)fluoranthene, and indeno(1,2,3-cd)pyrene were detected in excess of their action levels. Their maximum detected concentrations were used in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-2. The detected concentrations of benzo(a)pyrene, benzo(b)fluoranthene, and indeno(1,2,3-cd)pyrene were not indicative of significant carcinogenic human health risk. Thallium results are suspect and will not be used to drive further action. However, the detected arsenic concentration was indicative of potential carcinogenic human health risks. Further action is recommended at subzone 2.

6.5 SUBZONE 3 (BUILDINGS 102 AND 104)

The subsections below describe subzone 3, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 3 surface soil.

6.5.1 Subzone Description

Acids, solvents, and fuel from building operations were considered to be potential contaminants at Buildings 102 and 104. During the DQO Process, five soil sample locations were placed in subzone 3. However, due to the identification of a concrete pad in the area as a former hazardous waste storage area, an additional sample location was placed in the subzone. The additional sample was located next to the concrete pad. Six surface soil samples were collected from the area around Buildings 102 and 104. All of the analytical results can be found in Appendix D.

6.5.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the vicinity of Buildings 102 and 104 for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 6-4. Figure 6-4 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

Two SVOCs, benzo(a)pyrene and indeno(1,2,3-cd)pyrene, were detected in excess of their action levels, 100 µg/kg and 1,400 µg/kg, respectively. Benzo(a)pyrene was detected in excess of its action level at three sample locations (SS-01, 308 µg/kg; SS-04, 517 µg/kg; SS-06, 190 µg/kg). Indeno(1,2,3-cd)pyrene also was detected at SS-01 (1,650 µg/kg) in excess of its screening criteria. SVOCs detected below their screening values including 1,2,4-trichlorobenzene, 2-methylnaphthalene, anthracene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, fluoranthene, phenanthrene, and pyrene. Inorganics that were detected below the action levels included aluminum, barium, cadmium, chromium, copper, iron, lead, manganese, mercury, nickel, thallium, tin, vanadium, and zinc. VOCs detected below their action levels including 2-butanone, 2-hexanone, acetone, methylene chloride, tetrachloroethene, and toluene.

6.5.3 Conclusions and Recommendations

Acids, solvents, and fuel were considered potential contaminants in surface soil at subzone 3. Chemicals detected in excess of their action levels were analyzed further in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-2. Concentrations of benzo(a)pyrene and indeno(1,2,3-cd)pyrene were indicative of potential carcinogenic human health risks. Therefore, further action is recommended at subzone 3.

6.6 SUBZONE 4 (TRANSFORMER SITE NEAR BUILDING 675)

The subsections below describe subzone 4, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 4 surface soil.

6.6.1 Subzone Description

PCBs were considered to be potential contaminants in soil at the former transformer site near Building 675. Four surface soil samples were collected for analysis. All of the analytical results can be found in Appendix D.

6.6.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the vicinity of the former transformer site for SVOCs, PCBs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 6-5. Figure 6-5 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

A single SVOC, benzo(a)pyrene, was detected slightly in excess of its 100 µg/kg action level at a single sample location (SS-04, 110 µg/kg). SVOCs detected below their screening criteria included 1,2,4-trichlorobenzene, fluoranthene, and pyrene. Thallium was detected at all four sample locations, but was in excess of its 5.5 mg/kg action level at only two locations. Inorganics that were detected below their action levels included aluminum, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, silver, vanadium, and zinc. No PCBs were detected in excess of their action

levels at the former transformer site near Building 675. A single PCB, aroclor-1260, was detected at two sample locations below its action level.

6.6.3 Conclusions and Recommendations

PCBs from the former transformer site were considered to be potential contaminants subzone 4. However, no PCBs were detected in excess of their action levels in subzone 4. Thallium and benzo(a)pyrene were detected in excess of their action levels. The maximum detections of thallium and benzo(a)pyrene were used in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-2. The maximum detected concentration of thallium was indicative of significant noncarcinogenic human health risks. However, thallium results from this study are suspect as described in Section 1.8.2.1 and will not be used to drive further action. The detection of benzo(a)pyrene was not indicative of significant carcinogenic human health risks. Therefore, no further action is recommended for the former transformer site near Building 675.

6.7 SUBZONE 5 (FORMER BUILDING SITES NORTH END OF PARCEL E)

The subsections below describe subzone 5, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 5 surface soil.

6.7.1 Subzone Description

Metals, solvents, and fuels from former building operations and demolition debris were considered potential surface soil contaminants at subzone 5. Four surface soil samples were collected from the north end of Parcel E. All of the analytical results can be found in Appendix D.

6.7.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the northern portion of Parcel E – former building sites – for VOCs, SVOC, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals that detected in the surface soil samples are listed in Table 6-6. Figure 6-6 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

A single SVOC, benzo(a)pyrene, was detected slightly in excess of its 100 µg/kg action level at a single sample location (SS-02, 105 µg/kg). SVOCs detected below their screening values included 1,2,4-trichlorobenzene, acenaphthylene, anthracene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, fluoranthene, indeno(1,2,3-cd)pyrene, and pyrene. Inorganics that were detected below their action levels included aluminum, arsenic, barium, cadmium, chromium, iron, lead, manganese, mercury, nickel, thallium, tin, vanadium, and zinc. No VOCs were detected in excess of their action levels. 2-butanone, acetone, methylene chloride, and toluene were the only VOCs detected in surface soil at subzone 5.

6.7.3 Conclusions and Recommendations

Metals, solvents, and fuels from former building operations and their demolition debris were considered potential surface soil contaminants at subzone 5. Chemicals detected in excess of their action levels were analyzed further in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-2. The concentration of benzo(a)pyrene was not indicative of significant carcinogenic human health risks. Therefore, no further action is recommended.

6.8 SUBZONE 9 (BUILDING 103)

The subsections below describe subzone 9, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 9 surface soil.

6.8.1 Subzone Description

Fuel, oils, and PCBs were considered potential contaminants in surface soil at Building 103. These contaminants may have entered the soil during Building 103's use as a Power Plant. Four surface soil samples were collected from the vicinity of Building 103. Sample SS-01 was resampled during a second sampling effort and the resample was labeled SS-01(R). All of the analytical results can be found in Appendix D.

6.8.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the vicinity Building 103 for VOCs, SVOCs, PCBs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of

action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 6-7. Figure 6-7 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

No inorganics were detected in excess of their action levels. Inorganics detected below their screening criteria included aluminum, antimony, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, silver, thallium, tin, vanadium, and zinc. A number of SVOCs were detected in excess of their action levels in SS-01 but not at SS-01(R). Benzo(a)anthracene (40,100 µg/kg), benzo(a)pyrene (31,800 µg/kg), benzo(b)fluoranthene (48,900 µg/kg), benzo(k)fluoranthene (20,900 µg/kg), and indeno(1,2,3-cd)pyrene (15,600 µg/kg) were all detected in excess of their action levels in soil sample SS-01. Other SVOCs detected below of their action levels included 1,2,4-trichlorobenzene, acenaphthene, anthracene, benzo(g,h,i)perylene, carbazole, chrysene, fluoranthene, fluorene, phenanthrene, and pyrene. VOCs detected below their screening criteria included 2-butanone, 2-hexanone, 4-methyl-2-pentanone, acetone, methylene chloride, and toluene. A single PCB, aroclor-1254, was detected in excess of its 900 µg/kg action level at SS-01(R) (1,820 µg/kg) and SS-02(R) (2,160 µg/kg). There were no other PCBs detected.

6.8.3 Conclusions and Recommendations

Fuel, oils, and PCBs were considered potential contaminants in surface soil at Building 103. Several SVOCs and a single PCB (Aroclor-1254) were detected in excess of their action levels. Their maximum detected concentrations were used in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-2. Benzo(a)pyrene, benzo(b)fluoranthene, and benzo(k)fluoranthene were detected in excess of their action levels and at concentrations indicative of potential carcinogenic human health risks. The detected concentration of aroclor-1254 also was indicative of potential carcinogenic human health risks. Therefore, due to the nature of contamination at subzone 9, further action is recommended.

6.9 PARCEL E CONCLUSIONS AND RECOMMENDATIONS

Fuels, oils, metals, solvents, PCBs, and acids were considered to be potential soil contaminants at Parcel E during the DQO Process.

Thallium exceeded its action level at subzones 1, 2, and 4. However, thallium will not be used to drive further action as addressed in Section 1.8.2.1. Benzo(a)pyrene was detected in excess of its action level at subzones 4 and 5. However, these detections were not at concentrations indicative of human health risks. Therefore, there does not appear to be significant soil contamination at subzones 1, 4, or 5, and no

further action is recommended. Further action is recommended at subzone 2 where a detected concentration of arsenic was indicative of potential human health risks. An Interim Removal Action (IRA) is recommended at subzone 2 to remove potentially contaminated soil.

Further action is recommended at the remaining soil subzones (i.e., 3 and 9) due to possible contamination indicated by chemicals detected in excess of their action levels and at levels which could represent human health risks. 2-hexanone was detected in subzones 3 and 9, but not at levels indicative of human health risks. However, detections of benzo(a)pyrene and indeno(1,2,3-cd)pyrene were indicative of potential human health risks at subzones 3 and 9. Subzone 9 (Building 103) had detections of aroclor-1254, benzo(a)anthracene, benzo(b)fluoranthene, and benzo(k)fluoranthene which were indicative of potential carcinogenic risks. Due to the nature of contaminants detected in subzones 3 and 9 further action is recommended. A Supplemental SI should be performed at subzones 3 and 9. This Supplemental SI at Buildings 102, 103, and 104 should focus on confirming the suspected presence of contamination under the footprints of the buildings.

7.0 TRUMAN ANNEX BUILDING 223 (PARCEL F)

7.1 PARCEL DESCRIPTION

Building 223 (Equipment Repair Shop) (Figure 7-1) is currently used as storage for Port Services. Little is known about previous activities in the building; however, the name implies that naval support equipment was repaired at the building. A closed hazardous waste storage area is south of Building 223. Building 1287 is a closed galley that operated during the 1960s. Adjacent to Building 1287 was a motor pool that operated during the 1950s.

7.2 INVESTIGATION HISTORY

This section describes previous and current investigations for the Truman Annex Building 223 Parcel.

7.2.1 Previous Investigations

Existing documents include the USN-NFEC NAS Key West Predraft EBS Truman Annex; Excess Property (USN-NFEC, 1996a); the USN-NFEC NAS Key West Closure Report on Building 1276 (USN-NFEC, 1995); and the USN-NFEC NAS Key West Closure Report on Building 1287 (USN-NFEC, 1996b).

7.2.2 Current Investigation

The DQO Process evaluated six subzones for Parcel F. Subzones 2, 4, 5, and 6 were eliminated from further evaluation. Two subzones required sampling and analysis under the BRAC SI. The environmental medium of each subzone and the parameter groups selected for analysis at each subzone, are presented in Table 7-1. Subzone 1 (Former Lube Area) and subzone 3 (Building 223 Equipment Repair Shop) were identified as soil subzones. Four sample locations were placed within each subzone as shown on Figures 7-2 through 7-3, respectively. Analytical results for samples collected at Parcel F were compared to an industrial set of action levels (see Section 1.8.2.1).

Although the BRAC SI Workplan (B&R Environmental, 1998a) describes five groundwater subzones at Truman Annex, one at each Parcel (i.e., C, D, E, F, and K), the DQO Process considered the groundwater at Truman Annex as a single unit in the decision-making process. Discussion of sampling and analytical results for groundwater at Truman Annex (including Parcels C, D, E, F, and K) are included in Section 4.6. The location of four permanent monitoring wells and of a single previously existing monitoring well at Truman Annex are shown in Figure 4-5.

7.3 SUBZONE 1 (FORMER LUBE AREA)

The subsections below describe subzone 1, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 1 surface soil.

7.3.1 Subzone Description

Fuels, used oils, solvents, and metals were considered to be potential surface soil contaminants at the former lube area from ASTs (east side) supporting former garage facilities in Parcel F. Four surface soil samples were collected at subzone 1 during the SI field effort. All of the analytical results can be found in Appendix D.

7.3.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the vicinity of the former lube area for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 7-2. Figure 7-2 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

Two inorganics, arsenic and thallium, exceeded their surface soil action levels. The arsenic exceedance (5.2 mg/kg) was in a single sample (SS-04). Arsenic was detected at one other surface soil sample location (SS-01). Thallium was detected at all four soil sample locations but was considered to be in excess at only two locations (SS-01 and SS-03). Inorganics detected below their action levels include aluminum, barium, chromium, cobalt, copper, iron, lead, manganese, vanadium, and zinc. No VOCs were detected at the former lube area. A single SVOC, 1,2,4-trichlorobenzene, was detected at a single sample location at a concentration below its screening value.

7.3.3 Conclusions and Recommendations

Fuels, used oils, solvents, and metals from operations were considered to be potential surface soil contaminants at the former lube area from ASTs (east side) supporting former garage facilities in Parcel F. Two inorganics, arsenic and thallium, were detected in excess of their action levels. The maximum detected concentration of arsenic was used in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-3. The maximum

arsenic detection was indicative of potential carcinogenic human health risks, but not of noncarcinogenic risks. The thallium exceedance is suspect and will not be used to drive further action. However, due to the arsenic contamination at subzone 1, further action is recommended.

7.4 SUBZONE 3 (BUILDING 223 EQUIPMENT REPAIR SHOP)

The subsections below describe subzone 3, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 3 surface soil.

7.4.1 Subzone Description

Metals, fuels, and solvents were considered potential sources of contamination at subzone 3 from Building 223 which was used as an equipment repair shop and a plumbing shop, and from a neighboring hazardous waste storage area. Four surface soil samples were collected in the vicinity of the equipment repair shop. All of the analytical results can be found in Appendix D.

7.4.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the vicinity of Building 223 for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 7-3. Figure 7-3 shows the location of analytes that exceeded action levels and indicate possible surface soil contamination.

One inorganic, arsenic, exceeded its 2.7 mg/kg surface soil action level at two sample locations (SS-03, 3.2 mg/kg; SS-04, 16.8 mg/kg). Inorganics detected at concentrations below their action levels include aluminum, antimony, barium, cadmium, chromium, cobalt, copper, iron, lead, manganese, nickel, silver, thallium, vanadium, and zinc. No VOCs or SVOCs were detected in excess of their action levels. Acetone, methylene chloride, and toluene were the only VOCs detected at subzone 3. SVOCs detected below their screening criteria, included 1,2,4-trichlorobenzene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, fluoranthene, indeno(1,2,3-cd)pyrene, and pyrene.

7.4.3 Conclusions and Recommendations

Metals, fuels, and solvents from use of Building 223 as an equipment repair shop, and plumbing shop, and from a neighboring hazardous waste storage area were considered potential sources of contamination at Building 223. A single inorganic, arsenic, was detected in excess of its 3.7 mg/kg action level. The maximum detected concentration of arsenic was used in the estimated risk process as described in Section 1.8.2.2. Calculations and estimates can be found in Appendix C, Table C-3. The maximum detected concentration of arsenic was indicative of potential carcinogenic and noncarcinogenic human health risks. Therefore, further action is recommended.

7.5 PARCEL F CONCLUSIONS AND RECOMMENDATIONS

Fuels, oils, solvents, and metals were considered to be potential contaminants in soil at Parcel F during the DQO Process. An overview of the DQO Process is found in Section 3.0 of the BRAC SI Workplan, and subzone-specific criteria are found in Appendix B of the BRAC SI Workplan. Arsenic was detected in excess of its action level in both soil subzones. Both detections were indicative of potential carcinogenic human health risks and one of the exceedances was indicative of potential noncarcinogenic human health risks. Thallium was indicative of potential human health risks in subzone 1 but will not be used to drive further action. Due to the nature of potential human health risks in subzones 1 and 3, further action is recommended. An interim remedial action is recommended for subzones 1 and 3 to remove contaminated soil.

8.0 TRUMBO POINT PIERS D-1 AND D-3 (PARCEL H)

8.1 PARCEL DESCRIPTION

Trumbo Point Piers D1 and D3 (Figure 8-1) are two of three original harbor terminal piers constructed in 1914 by the Florida East Coast Railroad Company. The piers were used by the railroad and P.O. Steamship Company as part of an overseas railroad freight car ferry system. The piers were abandoned in 1935 after severe hurricane damage. Some time later Pier D3 was used as an oil dock by Orange State Oil Company. In August 1942, Pier D1 was purchased by the Navy from Trumbo Point Properties, Inc. Pier D3 was purchased from Orange State Oil Company in December 1942. The Navy used the property in support of various ship and craft operations until the late 1980s. A chain link fence has been installed along the length of Pier D1. The USCG uses the north side of the pier and the Naval Air Warfare Center uses the south side (including all buildings and structures). The Navy does not use Pier D3, but the USCG uses a fenced portion of the pier, including Building 45.

8.2 INVESTIGATION HISTORY

This section describes previous and current investigations for the Trumbo Piers D-1 and D-3 Parcel.

8.2.1 Previous Investigations

Existing documents include the USN-NPWC Lead and Asbestos Survey of Trumbo Point Pier (USN-NPWC, 1995c); the USN-SUPSHIP Predraft EBS Realignment Parcels (USN-SUPSHIP, 1996), and the USN-NFEC Preliminary CAR for Trumbo Point Fuel Farm (USN-NFEC, 1994b). No groundwater analytical data exist.

Based on the 1995 inspection performed by the NPWC, both LBP and ACBMs are present in Pier D1 buildings. Pier D3 appears to contain numerous areas of LBP, but no ACBMs are associated with current facilities, although it is likely that ACBMs have been used and handled there in the past.

The EBS (USN-SUPSHIP, 1996) documented a number of factors that are potentially helpful in characterizing the current physical condition of the site:

- Although the storage of hazardous or petroleum substances at the site in the past has been documented, no visible sheen or discoloration of surface water has been observed.

- No stains were observed on site soils, although numerous small stains that appear to be paint- or petroleum-related were noted throughout the site facilities.
- Two oily water flow-through process tanks are located at the northern corner of Pier D1. The tanks are not used by the present tenant.
- Pier D3 contains two USTs -- a 550-gallon waste-oil tank and a 250-gallon oily-waste tank. Both tanks have been abandoned. The fueling operations and associated piping have also been abandoned.
- The presence of PCBs is not suspected at Piers D1 or D3. Transformers at Pier D3 have been identified as non-PCB.
- Although pesticides are commonly used for mosquito and pest control throughout NAS Key West, there is no evidence of pesticide misuse at the site.

8.2.2 Current Investigation

The DQO Process evaluated six subzones for Trumbo Point Piers D-1 and D-3. Subzones 1, 2, 3, 4, and 5 were eliminated from further evaluation. One subzone within Parcel H required sampling and analysis under the BRAC SI. The parameter groups selected for analysis at this groundwater subzone are presented in Table 8-1. Four existing groundwater monitoring wells were used as the BRAC SI sample locations in subzone 6 as shown in Figure 8-2. Analytical results for samples collected at Parcel H were compared to an industrial set of action levels (see Section 1.8.2.1).

8.3 SUBZONE 6 (GROUNDWATER)

The subsections below describe subzone 6, present the contaminants detected, compare the detected concentrations with selected screening values, and provide conclusions on the SI findings for subzone 6 groundwater.

8.3.1 Subzone Description

Solvents and metals were considered potential groundwater contaminants at Parcel H, especially at the east end of Pier D-1 from potential leaks at an oil-water separator, and from past use of Piers D-1 and D-3. Four groundwater samples were collected from permanent groundwater monitoring wells at the east end of Pier D-1. All of the analytical results can be found in Appendix D.

8.3.2 Site Investigation Findings

Contamination was investigated by analyzing groundwater in monitoring wells at Parcel H for VOCs and inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the groundwater sample are listed in Table 8-2. Figure 8-2 shows the location of analytes that exceeded action levels and indicated possible groundwater contamination.

No chemicals were detected in excess of the screening criteria. 2-hexanone was the only VOC detected. Iron, lead, tin, vanadium, and zinc were the inorganics detected at concentrations below their action levels.

Monitoring well MW-42 was not sampled at the time the other samples were taken due to the presence of free-product. The NAS Key West Partnering Team subsequently decided to sample MW-42 during May 1998. No chemicals were detected in excess of action levels. Inorganics detected below action levels include aluminum, barium, chromium, copper, iron, lead, manganese, nickel, tin, vanadium, and zinc. No VOCs or SVOCs were detected. Free product recovery activities were then conducted at MW-42. The monitoring well was visited weekly for 4 weeks from July 22, 1998 to August 12, 1998. The product thickness was measured at each visit and an attempt was made to recover product at each visit. Each time, the product thickness was too thin to measure. Product recovery attempts resulted in the recovery of groundwater mixed with very small quantities of fuel (approximately 1 percent of the total).

Another groundwater sample was obtained from MW-42 in October 1998. No chemicals were detected in excess of action levels. Inorganics detected below action levels include chromium, iron, manganese, nickel, vanadium, and zinc. One SVOC, 2-methylnaphthalene, was detected below its action level.

8.3.3 Parcel H Conclusions and Recommendations

Solvents and metals were considered potential groundwater contaminants at subzone 6 during the DQO Process. An overview of the DQO Process is found in Section 3.0 of the BRAC SI Workplan, and subzone-specific criteria are found in Appendix B of the BRAC SI Workplan. No chemicals exceeded their action levels at subzone 6. Groundwater-to-surface-water migration of contaminants is possible at Trumbo Point, especially since groundwater at Key West is shallow. However, ecological receptors are not directly exposed to groundwater, and no groundwater thresholds have been developed based on ecological concerns. Therefore, groundwater concentrations of analytes that exceeded action levels and had no action levels were compared to surface-water screening values (where applicable) as a conservative scenario (e.g., no attenuation or dilution) in accordance with EPA Region 4 (EPA, 1995a)

and FDEP (FDEP, 1996b) requirements. 2-hexanone was detected in only one of the monitoring wells sampled at Parcel H. Its detected value was 48.8 µg/L. There are no EPA Region 4 nor FDEP ecological screening levels for this contaminant (EPA, 1995a; FDEP, 1996b). However, EPA Region 3 BTAG has established a screening level of 428,000 µg/L (EPA, 1995b) for 2-hexanone in fresh water (a value for saltwater was not available), which was established as the action level. Based on the infrequent detection of this contaminant, and the fact that its detected value was well below the available screening level, there is no evidence of ecological risks from 2-hexanone in groundwater at Parcel H.

Monitoring well MW-42 was sampled before and after free-product removal activities. No chemicals were detected in excess of action levels in either sample. Therefore, no further action is required at Parcel H.

9.0 WATERFRONT MAINTENANCE FACILITIES (PARCEL K)

9.1 PARCEL DESCRIPTION

Parcel K (Figure 9-1) includes Buildings 84, 112, 113, and 149. Building 113 is a Special Forces Operations Center (former Paint and Oil Storage). Building 149 is the NAS Key West Port Operations (Port Ops) Building (former Gear and Spare Parts Storage). Port Ops provides and maintains boats (less than 60 feet) to support naval activities for NAS Key West. The building also includes an active hazardous waste storage area. Building 84 is vacant, but it most recently was a Naval Convenience Store and formerly was a Transportation Pool. Building 112 is currently a Public Works Warehouse and formerly was used as a Submarine Spare Parts Building. Former buildings in the Parcel that have been razed include:

- 111 - Paint Shop/former Marine Railway Utilities (pre 1951)
- 137 - Outside Machine Shop/former Fitting Out Shop (pre 1951)
- 138 - Central Tool Room/former Galvanizing Shop (pre 1951)
- 139 - Pipe and Copper Shop
- 140 - Boiler Shop
- 141 - Foundry
- 143 - Lumber Shed
- 144 - Public Work Warehouse
- 145 - Patrol Craft (PC) Boat Shop
- 146 - Experimental Lab
- 150 - Echo Repeater Shop/former Paint Shop (pre 1951)
- 153 - Rigger's Shop/former Cafeteria Annex (pre 1951)

9.2 INVESTIGATION HISTORY

This section describes previous and current investigations for the Waterfront Maintenance Facilities Parcel.

9.2.1 Previous Investigations

Existing documents include the USN-NFEC NAS Key West Draft EBS Truman Annex Outer Mole Pier 8/ Buildings 149, 1374, 4080 (USN-NFEC, 1997); the USN-NFEC NAS Key West Predraft EBS Truman

Annex; Excess Property (USN-NFEC, 1996a); and the USN-NPWC Lead and Asbestos Survey of Truman Pier (USN-NFWC, 1996). No soil or groundwater analytical data exist.

9.2.2 **Current Investigation**

The DQO Process evaluated six subzones for Parcel K. Subzones 4, 6, and 7 were eliminated from further evaluation. Three subzones within Parcel K required sampling and analysis under the BRAC SI. The environmental medium of each subzone and the parameter groups selected for analysis at each subzone, are presented in Table 9-1. Subzone 1 (Building 149 Port Operations and Hazardous Waste Storage Area), subzone 2 (Remainder Public Works Maintenance Facilities), and subzone 3 (Building 84) were identified as soil subzones, and the four sample locations in each subzone are shown on Figures 9-2 through 9-4. Analytical results for samples collected at Parcel K were compared to an industrial set of action levels (see Section 1.8.2.1).

Although the BRAC SI Workplan (B&R Environmental, 1998a) describes five groundwater subzones at Truman Annex, one at each Parcel (i.e., C, D, E, F, and K), the DQO Process considered the groundwater at Truman Annex as a single unit in the decision-making process. Discussion of sampling and analytical results for groundwater at Truman Annex (including Parcels C, D, E, F, and K) are included in Section 4.6. The location of four permanent monitoring wells and of a single previously existing monitoring well at Truman Annex are shown in Figure 4-5.

9.3 **SUBZONE 1 (BUILDING 149 PORT OPERATIONS AND HAZARDOUS WASTE STORAGE AREA)**

The subsections below describe subzone 1, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 1 surface soil.

9.3.1 **Subzone Description**

Metals, solvents, fuels, acids, and used oils from hazardous waste storage area activities and handling of hazardous materials in Building 149 were considered potential sources of contamination in surface soil at Building 149. Four surface soil samples were collected from the vicinity of Building 149 during the SI field effort. All of the analytical results can be found in Appendix D.

9.3.2 **Site Investigation Findings**

Contamination was investigated by analyzing samples from surface soil in the vicinity Building 149 for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels were

selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 9-2. Figure 9-2 shows the sample locations of all surface soil samples collected at subzone 1.

No chemicals were detected in excess of their action levels in surface soil samples in the vicinity of Building 149. Methylene chloride was the only VOC detected in surface soil samples from subzone 1. SVOCs detected at concentrations less than their screening criteria included benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, chrysene, fluoranthene, indeno(1,2,3-cd)pyrene, and pyrene. Inorganics detected below their action levels include aluminum, arsenic, barium, chromium, copper, iron, lead, manganese, mercury, thallium, vanadium, and zinc.

9.3.3 Conclusions and Recommendations

Metals, solvents, fuels, acids, and used oils from hazardous waste storage area and Building 149 were potential sources of contamination in surface soil at Building 149. However, no chemicals were detected in excess of screening criteria. Therefore, there does not appear to be significant contamination in surface soil at Building 149 and no further action is recommended.

9.4 SUBZONE 2 (REMAINDER PUBLIC WORKS MAINTENANCE FACILITIES)

The subsections below describe subzone 2, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 2 surface soil.

9.4.1 Subzone Description

Metals, solvents, fuels, and acids were considered potential sources of contaminants from former building uses, former fuel lines, and demolition debris in the remainder public works maintenance facilities. Four surface soil samples were collected in subzone 2. All of the analytical results can be found in Appendix D.

9.4.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil in the remainder public works maintenance facilities area for VOCs, SVOCs, and inorganics. The results of these analyses were compared with action levels selected from a variety of sources including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research

institutions. The selection of action levels is discussed in Section 1.8.2.1. Chemicals detected in the surface soil samples are listed in Table 9-3. Figure 9-3 shows the sample locations of all surface soil samples collected at subzone 2.

No chemicals were detected in excess of their action levels in surface soil samples in the vicinity of the Remainder Public Works Maintenance Facilities. Acetone and methylene chloride were the only VOCs detected in surface soil samples from subzone 2. SVOCs detected at concentrations less than their screening criteria included 2-chlorophenol, anthracene, benzo(b)fluoranthene, fluoranthene, phenanthrene, and pyrene. Inorganics detected below their action levels include aluminum, barium, chromium, copper, iron, lead, manganese, mercury, thallium, vanadium, and zinc.

9.4.3 Conclusions and Recommendations

Metals, solvents, fuels, and acids from former building uses, former fuel lines, and demolition debris were considered potential sources of contamination in surface soil at the Remainder Public Works Maintenance Facilities. No chemicals were detected in excess of their action levels. Therefore, there does not appear to be significant contamination in the surface soil in subzone 2 and no further action is recommended.

9.5 SUBZONE 3 (BUILDING 84)

The subsections below describe subzone 3, present the contaminants detected, compare the detected concentrations with selected soil screening values, and provide conclusions on the SI findings for subzone 3 surface soil.

9.5.1 Subzone Description

Metals were considered potential contaminants from Building 84's use as a transportation pool. Four surface soil samples were collected in subzone 3. All of the analytical results can be found in Appendix D.

9.5.2 Site Investigation Findings

Contamination was investigated by analyzing samples from surface soil at Building 84 area for inorganics. The results of these analyses were compared with action levels selected from a variety of sources, including background levels as discussed in Section 1.8.1.1 and ARARs and SALs from various state and Federal agencies and research institutions. The selection of action levels is discussed in Section 1.8.2.1.

Chemicals detected in the surface soil samples are listed in Table 9-4. Figure 9-4 shows the sample locations of all surface soil samples collected at subzone 3.

Several inorganics were detected in surface soil at subzone 3, but none in excess of their action levels. These included aluminum, antimony, arsenic, barium, chromium, copper, iron, lead, manganese, mercury, vanadium, and zinc.

9.5.3 Conclusions and Recommendations

Metals as a result of Building 84's use as a transportation pool were considered to be potential sources of contamination in surface soil. However, no chemicals were detected in excess of action levels. Therefore, there does not appear to be significant contamination in the surface soil in subzone 3 and no further action is recommended.

9.6 **PARCEL K CONCLUSIONS AND RECOMMENDATIONS**

Fuels, oils, metals, solvents, and acids were considered potential contaminants in soil at the Waterfront Maintenance Facilities during the DQO Process. However, no chemicals were detected in excess of their action levels. Therefore, there does not appear to be significant soil contamination at the Waterfront Maintenance Facilities and no further action is recommended.

TABLE 9-1
PARAMETER GROUPS AND MEDIA OF INTEREST AT THE WATERFRONT
MAINTENANCE FACILITIES (PARCEL K)
NAS KEY WEST

Subzone	Building/Area	Medium	Number of Locations	Parameter Group				
				VOCs	SVOCs	Inorganics	PCBs	Pesticides
Subzone 1	Building 149 Port Operations and Hazardous Waste Storage Area	SO	4	X	X	X		
Subzone 2	Remainder Public Works Maintenance Facilities	SO	4	X	X	X		
Subzone 3	Building 84	SO	4			X		

SO = Surface soil

Subzones 4, 6, and 7 were eliminated from sampling during the DQO Process.

APPENDIX A

**RESPONSE TO COMMENTS ON
THE SITE INSPECTION REPORT FOR NINE BRAC PARCELS
NAVAL AIR STATION
KEY WEST, FLORIDA**

APPENDIX A. RESPONSE TO COMMENTS

RESPONSE TO COMMENTS FROM JORGE CASPARY, FDEP

1. **General Comment:** It is interesting to note that thallium and no other inorganic constituent has been detected in soil samples for the majority of the sites described in the referenced document. I recommend that the laboratory data for inorganic constituents be properly reviewed for quality assurance and quality control protocols. I also recommend that the Navy considers resampling soil at some sites via auger drilling.

Response: J. Samchuck (TtNUS – Pittsburgh Office Validation Group) revisited several packages from the SI data set and verified that the data reported for thallium is correct. He performed a re-validation for inorganic data and concluded that there is nothing in the data set that would indicate that the results for thallium were inaccurate. However, due to the consistency of the detection levels and frequency that thallium was detected (70.4%), it appears to be a systematic equipment error from the lab. During Supplemental SI field investigations, thallium was not detected in BRAC Parcels where it was detected during the SI. The NAS Key West Partnering Team agreed during its October 1998 meeting that the thallium detections reported during the SI are suspect and will not be used to drive further action.

2. **General Comment:** FDEP concurred with all subzone recommendations.

Response: Comment noted.

RESPONSE TO COMMENTS FROM M. BERRY, U.S. EPA REGION 4

1. **Comment:** Parcel A, subzones 5, 6, 10 and 11 are recommended for No Further Action (NFA). Subzones 4 and 9 are recommended for further action. EPA concurs with these recommendations.

Response: Comment noted.

2. **Comment:** Parcel A, subzone 1 was recommended for further action based on a single hit of dibenzo(a,h)anthracene. Subzone 1 is where telephone poles made of treated lumber were formerly stored. Since the finding probably resulted from the telephone poles, the NAS Key West Partnering Team has agreed that no further action is warranted.

Response: Concur. This issue was discussed at the July 1998 NAS Key West Partnering Team meeting as noted. Changes will be made to the applicable text in Section 2 of the report to incorporate this change.

3. **Comment:** Parcel A, subzone 7 is recommended for further action based solely on the presence of thallium. As agreed to in the July 1998 NAS Key West Partnering Team Meeting, this decision should be deferred until we have a better idea of the source of the thallium.

Response: Further action for Parcel A, subzone 7 was driven by the detection of thallium. See response to general comment from FDEP. No further action is needed for this subzone. Text for this subzone will be reworded accordingly.

4. **Comment:** Parcel B, subzones 1 and 3 are recommended for NFA. EPA concurs with these recommendations.

Response: Comment noted.

5. **Comment:** Parcel C, subzones 1, 3 and 4 are recommended for further action. EPA concurs with these recommendations.

Response: Comment noted.

6. **Comment:** The draft SI Report recommends an RI for the groundwater at Truman Annex. Because the only issue is the phenanthrene hit in K05-MW1, the NAS Key West Partnering Team has decided to explore other avenues of addressing this potential problem.

Response: Since the delivery of Revision 0, it has been determined that benzene was also detected in excess of its action level at K05-MW-01. Section 4.7 (Parcel C and Truman Annex

Groundwater) will be reworded to remove the RI and incorporate a recommendation for additional activities as determined by the NAS Key West Partnering Team.

7. **Comment:** Parcel D, subzones 1 and 2 are recommended for NFA. EPA concurs with these recommendations.

Response: Comment noted.

8. **Comment:** Parcel E, subzone 5 is recommended for NFA. Parcel E, subzones 2, 3 and 9 are recommended for further action. EPA concurs with these recommendations.

Response: Comment noted.

9. **Comment:** Parcel E, subzones 1 and 4 is recommended for further action based solely on the presence of thallium. As agreed to in the July 1998 NAS Key West Partnering Team meeting, this decision should be deferred until we have a better idea of the source of the thallium.

Response: See Comment 4 and response.

10. **Comment:** Parcel F, subzones 1 and 3 are recommended for further action. EPA concurs with these recommendations.

Response: Comment noted.

11. **Comment:** Parcel H, subzone 6 is currently undergoing free product removal from MW-42. MW-42 has also been sampled for chlorinated solvents. A decision for further action will await results from these two activities.

Response: Concur. MW-42 was sampled on May 15, 1998. Aluminum, iron, and zinc were the only chemicals detected in groundwater at MW-42 (645 µg/L, 1,010 µg/L, and 37.4 µg/L, respectively). All detections were well below the applicable screening criteria (37,000 µg/L, 11,000 µg/L, and 1,100 µg/L, respectively). 2-hexanone was considered as an exceedance in subzone 6 at Parcel H (MW-41, 48.8 µg/L) in Revision 0 of the SI Report. However, at the July 1998 Partnering Team meeting, an action level of 4.28E5 µg/kg was approved for 2-hexanone. During its October 1998 meeting, the NAS Key West Partnering Team decided to resample MW-42. This groundwater resample was obtained on October 15, 1998, which again detected no chemicals above action levels. The NAS Key West Partnering Team concurred that no further action is required for the Parcel H groundwater (Parcel H, subzone 6).

12. **Comment:** Parcel K, subzones 1, 2 and 3 are recommended for NFA. EPA concurs with these recommendations.

Response: Comment noted.

APPENDIX B
FIELD DOCUMENTATION

TABLE OF CONTENTS

SECTION

PART 1	WORKPLAN AMENDMENTS AND DEVIATIONS
PART 2	FIELD DATA SHEETS
PART 3	SURVEY DATA

PART 1 – WORKPLAN AMENDMENTS AND DEVIATIONS

The SI field effort for the BRAC properties at NAS Key West, Florida was conducted November, 1997 to March, 1998 in accordance with the SI Workplan for Ten BRAC Properties Naval Air Station Key West, Florida (B&R Environmental, 1998a). In several instances, the SI Workplan required changes based on existing field condition/technical decisions in order to meet project objectives. These deviations from the workplan are described below.

1. Use of polyethylene tubing

Polyethylene tubing was used to sample permanent wells at Truman Annex during groundwater screening sample collection. Teflon tubing that meet the cleaning specifications was not received in time to sample these wells.

2. MW-26 was resampled

MW-26 was resampled after Teflon tubing meeting the cleaning specifications was received. Analytical results from the resample [MW-26(R)] were used as the basis for discussion in SI results and conclusions.

3. Coring/logging not necessary on all groundwater screening samples

Coring/logging was not performed on all groundwater screening samples. It was performed on a sufficient number of samples in a given area to adequately establish the depth to the water table and the local lithology. Coring itself does not slow the Direct Push Technology (DPT) process, however it does create the need for additional decontamination, which requires additional time.

4. Sample E07-GS-01 was removed and replaced with F07-GS-10

Concrete was encountered at 2 feet while the DPT rig was pushing sample E07-GS-01. This sample location was moved across park road into Parcel F in order to maintain groundwater screening coverage. The new sample location was named F07-GS-10.

5. Samples E07-GS-06, 07, and 08 were renamed E07-MW-27, 26, and 22, respectively

Existing wells were located at the originally intended site of the screening samples. The wells were sampled rather than have the DPT rig push new holes and install temporary wells at these locations. Sample names were changed to correctly identify the wells sampled.

6. VOCs and SVOCs were added to the soil samples in Truman Annex DRMO Waste Storage Area (Parcel C) subzone 4

Hydraulic fluid stains were observed on the pavement at the site, establishing a possibility for contamination other than metals. Samples were analyzed for VOCs and SVOCs to determine if contamination exists.

7. Samples added to subzones 3 and 4 at Truman Annex DRMO Waste Storage Area (Parcel C)

While in the field, the NAS Key West Partnering Team decided to add four soil samples to subzones 3 and 4 based on the potential re-use of this site as a day-care center. Due to the increased possibility of soil contact based on this scenario additional sampling was considered necessary to ensure total coverage.

8. Storage areas for IDW

Aqueous IDW for all Truman Annex sites was stored at Building 223 based, where access to the drum by the public was restricted. The IDW generated at the interior sites was stored at Hawk Missile Site Building 6532. Every effort was made to segregate IDW by Parcel. However, many partially filled drums would have resulted from strict segregation. The contents of all drums were carefully documented. In addition, it was not practical to segregate DPT decon IDW by Parcel.

9. Hand auger Truman Annex Buildings 102, 103, and 104 (Parcel E) subzone 4 samples

Because of the proximity of active transformers at this location, caution seemed advisable to ensure the safety of the field team. The field crew did not use DPT to collect these soil samples. Hand auguring was employed as the sample method.

10. Hand augering a single soil sample in Hamaca Hawk Missile Site (Parcel A) subzone 7

Hand augering was used to collect one soil sample in subzone 7. The sample location was not accessible to the DPT rig.

11. Sample F07-GS-10 was not analyzed for inorganics

Due to a labeling error, the sample (F07-GS-10) could not be distinguished from an extra volume pulled from a different location. The temporary well screen was removed before the discovery of this error; therefore, another sample could not be collected.

12. Hamaca Hawk Missile Site (Parcel A) subzone 1 was divided

A significant portion of the original subzone 1 had standing water during the initial field visit. The portion of Parcel A subzone 1 inside the fence line was underwater and displayed mangrove growth, demonstrating that inundation is not infrequent or transitory. Therefore, that portion was included in subzone 9, the sediment subzone and four additional sediment samples were located there. Subzone 1 became only the portion outside of the fence and four soil samples were collected there.

13. Preservative rinsed out of VOC groundwater sample bottles

The VOC groundwater samples collected during February 1998, effervesced because of the interaction of CaCO_3 in the groundwater and the HCl preservative, creating a headspace within the sample bottles. On February 23, 1998, B&R Environmental field personnel discussed this with the laboratory who recommended that the sample bottles be rinsed with groundwater from the well to be sampled to remove the preservative prior to sample collection. Removing the preservatives decreased the holding time from 14 to 7 days. All permanent monitoring wells sampled after February 23, 1998, were treated in this manner.

GROUNDWATER SCREENING SAMPLE LOG SHEET

Sample Name: **A11-GS-07**

Project: **NAS Key West BRAC SI**

Project Number: **7593**

Zone: **A - Hawk Missile Site**

Subzone: **GRYZNA-SZN11**

Airbill No: _____

Laboratory: **GEL**

Total Depth (ft):	7.63
Stickup Height (ft):	.25
Casing Diameter (ID-inches):	1/2"
Static Water Level (ft below top of casing):	3.88'
One Casing Volume (gal):	
Start Purge (hrs.):	09:15
End Purge (hrs.):	11:21
Total Purge Time (min.):	126
Total Amount Purged (gal):	8.25
Purge Method:	Peristaltic pump with polyethylene (PE) tubing (silicon tubing in pump head)
Sample Method:	VOCs by gravity flow from PE tubing, all other fractions pumped using peristaltic w/ PE tubing (silicon in pump head).
Depth Sampled:	
Sample Date:	12-11-97
Sample Time:	11:25

Type of Screening Sample:		Type of Sample:	
<input checked="" type="checkbox"/> DPT Borehole	<input type="checkbox"/> Existing Monitoring Well	<input checked="" type="checkbox"/> Low Concentration	<input type="checkbox"/> High Concentration

If Sample Location was Changed from that Designated in the Workplan, The Rationale is Provided Here, along with a Description of the New Location:

"R" - duplicate resample due to high SVOCs.

Observations/Notes:

- Resample placed adjacent to original sample. Concrete core was used. - sample was overlain by 1 to 2 inches of asphalt, but no significant amount of concrete was encountered in this location.
- A concerted effort was made to pick out asphalt fragments, but some frags. were very small + not as likely since asphalt is contained in sample.
- Sample was moist to wet due to water used a

ANALYSES: lubricant in water.

If Sample Location was Changed from that Designated in the Workplan, The Rationale is Provided Here, along with a Description of the New Location:

No contaminants were previously detected in this location where there was obviously leakage from the adjacent waste oil tank, so this location was resampled.

Observations/Notes:

Waste oil tank is obviously still leaky - can see drips of dark liquid fall from tank onto pad adjacent to sample location.
Sample collected from soil just off edge of pad. Soil is obviously dark + stained.

Observations/Notes: (Any change in sample location from that designated in the Workplan should be explained and described here.)

This point was added in Zone F when DPT encountered concrete @ 2' in E07-GS-01. E07-GS-10 is located just across Service + park road from E07-GS-01. (This was also the location originally designated in the WP for E07-GS-04, which was moved to the area in front of 123A + 22b in order to equalize sample point distribution.

APPENDIX C

ESTIMATED RISK PROCESS

C.1 ESTIMATED RISK PROCESS FOR SURFACE SOIL SUBZONES

Human health risk estimates were calculated for chemicals detected in excess of their action levels. These estimates were based on human health risk assessments in the Supplemental RFI/RIs for sites at NAS Key West (B&R Environmental, 1997 and 1998) if risk values were available for compounds in question. When one or two risk values were available for a given compound, estimates were based on a ratio of detected concentrations to risk values. When there were two ratios for a single chemical, the more conservative resulting estimated risk was used. When three or more risk values were available for a given compound, estimates were calculated from a trend analysis. Representative concentrations from the Supplemental RFI/RI Investigations were used for the x-axis and corresponding risk values were used for the y-axis and a trend line was fitted to these values. The line was used to estimate risk values for new detected concentrations. In instances where risk values were not available from the Supplemental RFI/RI Investigations for a given compound, generic RGOs were used as benchmarks. Benchmarks were concentrations representative of a carcinogenic risk of 1.0×10^{-6} or a noncarcinogenic hazard index of 1.0. Maximum detected concentrations from SI analytical results were used in the SI estimated risk process.

Subzones were analyzed based on proposed future uses and potential receptors: residential, trespasser, and site/occupational worker. Tables C-1 through C-3 contain risk values from the Supplemental RFI/RI Investigations and the estimated risks for chemicals detected in excess of their action levels in surface soil subzones by future use category and chemical.

C.2 ESTIMATED RISK PROCESS FOR THE SEDIMENT SUBZONE

Parcel A, subzone 9 was the only sediment sampling location. Concentrations of seven metals, two phthalates, and one organochlorine pesticide detected in sediment exceeded ecological guidelines used in this report. None of these chemicals in surface-water samples taken from the same locations exceeded ecological guidelines and none in groundwater at the site exceeded action levels. Table C-4 gives the sediment guidelines for these 10 chemicals. A discussion of the ecological significance of these exceedances requires a brief overview of other guideline values for the same contaminants, which also are shown in Table C-4.

Effects range-low (ER-L) and threshold effects level (TEL) values were developed by the National Oceanic and Atmospheric Administration (NOAA) and FDEP, respectively. These values are used to identify sediment concentrations below which adverse ecological effects would rarely be observed. Sediment concentrations in the range between the ER-L and the effects range-median (ER-M) or between the TEL and the probable effects level (PEL) represent concentrations anticipated to be occasionally associated with adverse effects. Concentrations greater than the ER-M or PEL are anticipated to be frequently associated with adverse effects. Therefore, ascribing risk to a sediment contaminant detected at a concentration that exceeds the TEL (or ER-L) but below the PEL (or ER-M) can be misleading. With this in mind, the ecological significance of the sediment exceedances is discussed below.

Cadmium exceeded the TEL value in three samples. However, the highest concentration was 0.89 ppm, which is only slightly greater than the TEL, considerably less than the PEL, and less than the ER-L. Copper exceeded the TEL in only one sample (20.15 ppm). This value was only slightly greater than the TEL, considerably less than the PEL, and less than the ER-L. Thus, cadmium and copper detections in sediment do not appear to pose ecological risks at Hamaca Hawk Missile Site. Lead was detected in 7 of 8 sediment samples, but all detected values (except sample SD-05; 466 ppm) were less than the ER-M and PEL. Lead does not appear to pose ecological risks, except potentially in the vicinity of sample SD-05.

No sediment ecological guidelines were available for aluminum or vanadium. Instead, concentrations of these two metals were compared to twice the average background values, which were exceeded in samples SD-07 and SD-08. The vanadium concentrations only slightly exceeded twice the average background value. Vanadium is rarely highly toxic in the environment (Mailman, 1980). Zinc exceeded ecological guidelines in only one sediment sample (SD-04, 518 ppm); this value was greater than both the ER-M and PEL. Sample SD-04 was also the only sample in which barium was detected.

Bis(2-ethylhexyl)phthalate and butyl benzyl phthalate were detected only in sample SD-05. The detected concentration of bis(2-ethylhexyl)phthalate was 710 ppb, which is less than the PEL and the Region 3 BTAG ecological benchmark. The single butyl benzyl phthalate value (292 ppb) was considerably less than the EPA Sediment Quality Benchmark of 11,000 ppb. 4,4'-DDE was detected in two samples; concentrations in both samples only slightly exceeded the TEL and ER-L values and were considerably less than the PEL and ER-M values.

In summary, most sediment chemicals that exceeded ecological guidelines only slightly exceeded the TEL values, and/or were infrequently detected. However, lead in sample SD-05 could potentially pose ecological risks. In addition, five chemicals in sample SD-05 exceeded the most conservative ecological

guidelines, more chemicals than in any other sample. Further sampling in the vicinity of sample SD-05 may serve to better characterize the nature and extent of sediment contamination and associated potential ecological risks.

C.3 ESTIMATED RISK PROCESS FOR TRUMAN ANNEX GROUNDWATER SUBZONE

Analytes that exceeded action levels in groundwater samples were limited to benzene and phenanthrene. These organic compounds were detected in only one monitoring well (K05-MW-01). Ecological receptors are not directly exposed to groundwater, and no groundwater screening values have been developed based on ecological concerns. Therefore, groundwater concentrations of benzene and phenanthrene were compared to surface water screening values in accordance with EPA Region 4 (1995b) and FDEP requirements.

The EPA Region 4 ecological screening value for benzene in marine surface water is 109 µg/L (EPA, 1995b). The FDEP ecological screening value for benzene in marine surface water is 71.28 µg/L. (FDEP, 1996). The single detected concentration of benzene (1.2 µg/L) is well below both the FDEP and EPA Region 4 criteria. Therefore, based on the infrequent detection of this contaminant, and its detected value well below the available screening levels, there is no evidence of ecological risks from benzene in groundwater at the site.

EPA Region 4 has not established an ecological screening value for phenanthrene in surface water, but EPA's Office of Solid Waste and Emergency Response recommends an ecological screening value of 8.3 µg/L for phenanthrene in marine surface water (EPA, 1996). FDEP has established an ecological screening value in marine surface water of 0.031 µg/L (annual average) for the total concentration of the following PAH compounds: acenaphthylene, benzo(a)pyrene, benzo(b)fluoranthene, chrysene, benzo(k)fluoranthene, benzo(g,h,i)perylene, dibenzo(a,h)anthracene, ideno(1,2,3-cd)pyrene, and phenanthrene (FDEP, 1996). Since phenanthrene was the only one of these PAH compounds detected in groundwater, the screening value of 0.031 µg/L is applicable to phenanthrene in this case. The detected concentration of phenanthrene (187 µg/L) is well above both the EPA Region 4 and FDEP criteria.

In order for groundwater contaminants to pose risks to ecological receptors, groundwater must discharge into surface water or sediment. The direction of groundwater flow in the vicinity of monitoring well K05-MW-01 has not been determined. However, surface water bodies are potentially down gradient from this well if the flow of groundwater is toward the northwest, north, east, or southeast. A water-filled moat surrounding Fort Zachary Taylor is located approximately 75 feet northwest of the monitoring well. Open water of the Gulf of Mexico lies approximately 600 feet north of the well. Key West's "Inner harbor" is

located to the east and southeast of the well, and is approximately 300 feet from the well at its nearest point.

The maximum expected phenanthrene groundwater concentration at these three potential exposure points were evaluated using ECTran modeling (Appendix C.4). The modeling indicated that, depending on the size of the groundwater plume, a westward groundwater flow would reach the moat in 2 to 4 years and result in a maximum groundwater concentration of 21 to 76 $\mu\text{g/L}$ at the point of entry into the moat. However, since phenanthrene was not detected in screening sample GS-02, taken directly between the moat and well # K05-MW-01, significant westward migration apparently does not exist. A northward flow would reach the Gulf of Mexico in 22 years, and the maximum concentration would be 0.000912 to 0.00183 $\mu\text{g/L}$. However, phenanthrene was not detected in screening sample GS-01, located north of well # K05-MW-01 (Figure 4-20, SI Workplan). In addition, the predicted maximum concentrations are well below EPA and FDEP screening values. An eastward flow would reach the harbor in 14 years, and the maximum concentration would be 0.0824 to 0.144 $\mu\text{g/L}$. These values are slightly greater than the FDEP criteria of 0.031 $\mu\text{g/L}$, but much less than the EPA criteria of 8.3 $\mu\text{g/L}$. However, there are several monitoring wells to the east and southeast of well # K05-MW-01 (Figure 4-20, SI Workplan). Phenanthrene was not detected in any of these wells.

In summary, phenanthrene was detected in only one monitoring well. Phenanthrene was not detected in any sample between this well and nearby surface water bodies. These results, combined with the results of groundwater modeling, suggest that there is no migration of phenanthrene-contaminated groundwater to nearby water bodies. Therefore, the potential for risks to ecological receptors appears to be negligible.

C.4 ECTRAN MODELING OF PHENANTHRENE IN TRUMAN ANNEX GROUNDWATER

C.4.1 EcTran Modeling to Gulf of Mexico and the "Inner Harbor"

Objectives

Potential impacts of phenanthrene groundwater plume identified at the BRAC Parcel K Site need to be evaluated. Quantitative estimates of the maximum phenanthrene groundwater concentration at the nearest potential groundwater exposure points (receptors) are required for this evaluation. An ECTran modeling task was conducted to provide the necessary estimates to support the evaluation. This memo summarizes the modeling approach used and the results obtained.

General Approach

Site-specific groundwater flow and contaminant transport model were developed following a general modeling approach. The following steps are included in the general approach:

- Define the existing groundwater plume – The uncertainties exist in the determination of plume size because of only one groundwater sample. To be conservative, two simulations were conducted based on the different plume sizes. One simulation was based on the plume as big as 200 feet by 200 feet and another simulation was based on the plume size of 100 feet by 100 feet. The concentration of 192 ug/L from sample was assumed as the initial plume concentration.
- Conceptualized the hydrogeological conditions – Groundwater flow direction and velocity were defined based on your Email and our phone conversation (see the following SITE-SPECIFIC ASSUMPTIONS).
- Identify the nearest potential exposure point – Based on the groundwater flow direction, the phenanthrene groundwater concentration at two receptors were simulated. One receptors is 600 feet from the initial plume and another receptor is 300 feet from the initial plume.
- Estimate the maximum groundwater concentration at the exposure point – ECTran model simulations were conducted to determine the phenanthrene maximum groundwater concentrations at the receptors within a 1000 years simulation time frame.

Site-Specific Assumptions

The site-specific assumptions in the modeling task are summarized below:

- Soil Concentration – 0 (Soil is not contaminated)
- Plume Size – 200 feet x 200 feet and 100 feet x 100 feet
- Exposure Point (Receptor) – 600 feet and 300 feet from the initial plume
- Hydraulic Conductivity – 73 feet /day (Average of 9.6 feet/day and 136.8 feet/day)
- Hydraulic Gradient – 0.0062 (Average of 0.00133 and 0.011)

- Effective Porosity – 0.3 (Assumed)
- Infiltration Rate – 10 inches/year (Assumed as a quarter of the rainfall)
- Plume thickness – 9.2 feet (for 200 feet by 200 feet plume), and 6.1 feet (for 100 feet by 100 feet) (calculated from mixing depth formula, Chiou, et al., 1993)
- Initial Phenanthrene Groundwater Concentrations – 192 ug/L (sample value)
- KOC – 5240 (Abdul et al., 1987)
- Foc – 0.002 (EPA, 1996)
- Partition coefficient – 10.5 L/kg (equal to KOC x Foc)
- Half life – 2.2 years (Howard et al., 1991)

Summary of Results

Table C-5 lists the simulated phenanthrene maximum groundwater concentrations at the receptors within 1,000 years.

C.4.2 EcTran Modeling to the Moat at Fort Zachary Taylor

Objectives

Potential impacts of phenanthrene groundwater plume identified at the BRAC Parcel K Site need to be evaluated. Quantitative estimates of the maximum phenanthrene groundwater concentration at the nearest potential groundwater exposure points (receptors) are required for this evaluation. An EcTran modeling task was conducted to provide the necessary estimates to support the evaluation. This memo summarizes the modeling approach used and the results obtained.

General Approach

A site-specific groundwater flow and contaminant transport model was developed following a general modeling approach. The following steps are included in the general approach:

- Define the existing groundwater plume – The uncertainties exist in the determination of plume size because only two groundwater samples were available. To be conservative, two simulations were conducted based on the different plume sizes. One simulation was based on the plume as big as 100 feet by 100 feet and another simulation was based on the plume size of 50 feet by 50 feet. The concentration of 192 µg/L from sample was assumed as the initial plume concentration.
- Conceptualized the hydrogeological conditions - Groundwater flow direction and velocity were defined based on your Email and our phone conversation (see the following Site-Specific Assumptions).
- Identify the nearest potential exposure point - Based on the groundwater flow direction, the phenanthrene groundwater concentration at the edge of the Moat were simulated. The distance from the edge of the Moat to the edge of the plume is 15 ft for plume size of 100 ft by 100 ft and 45 ft for the plume size of 50 ft by 50 ft (As shown in the Figures).
- Estimate the maximum groundwater concentration at the exposure point - ECTran model simulations were conducted to determine the phenanthrene maximum groundwater concentrations at the receptor (edge of the Moat) within a 1000 years simulation time frame.

Site-Specific Assumptions

The site-specific assumptions in the modeling task are summarized below:

- Soil Concentration – 0 (Soil is not contaminated)
- Plume Size – 100 feet x 100 feet and 50 feet x 50 feet
- Exposure Point (Receptor) – 15 feet and 45 feet from the initial plume
- Hydraulic Conductivity – 73 feet /day (Average of 9.6 feet/day and 136.8 feet/day)
- Hydraulic Gradient – 0.0062 (Average of 0.00133 and 0.011)
- Effective Porosity – 0.3 (Assumed)

- Infiltration Rate – 10 inches/year (Assumed as a quarter of the rainfall)
- Plume thickness – 6.1 feet (for 100 feet by 100 feet plume), and 4.1 feet (for 50 feet by 50 feet) (calculated from mixing depth formula, Chiou, et al., 1993)
- Initial Phenanthrene Groundwater Concentrations – 192 µg/L (sample value)
- KOC – 5240 (Abdul et al., 1987)
- Foc – 0.002 (EPA, 1996)
- Partition coefficient – 10.5 L/kg (equal to KOC x Foc)
- Half life – 2.2 years (Howard et al., 1991)

Summary of Results

Table C-6 lists the simulated Phenanthrene maximum groundwater concentrations at the receptor within 1,000 years.
