Remedial Investigation Report
Site 46 (Former Building 72)
Naval Air Station Pensacola, Florida

This Remedial Investigation Report was prepared under the direct supervision of the undersigned geologist using geologic and hydrogeologic principles standard to the profession at the time the report was prepared in general conformance with the Requirements of Chapter 62-770, Florida Administrative Code. If conditions are determined to exist that differ from those described, the undersigned geologist should be notified to evaluate the effects of additional information on the assessment described in this report. This report was developed specifically for the referenced site and should not be construed to apply to any other site.

EXECUTIVE SUMMARY

The purpose of the Remedial Investigation (RI) at Site 46 – Former Building 72, was to provide data to guide the selection of a remedy that is protective of human health and the environment for environmental contamination found at the site.

SITE HISTORY

Buildings 71 and 72 were used from 1935 up to the late 1970's for aircraft paint stripping and painting. Before 1973, wastes from paint stripping and painting operations were discharged directly to Pensacola Bay.

PREVIOUS INVESTIGATION NEAR SITE 46

An RI was conducted at Site 38 - former Building 71, east of Site 46, and reported metals, semivolatile organic compounds (SVOCs), pesticides, polychlorinated biphenyls (PCBs), and volatile organic compounds (VOCs) in site soil beneath the Building 71 footprint. Parameters reported in groundwater included metals, SVOCs, and VOCs.

NATURE AND EXTENT OF CONTAMINATION

The release of contaminants at Site 46 probably resulted from routine aircraft maintenance activities and storage of materials used in these activities. The detections of chlorinated volatile organic compounds (CVOCs) and metals at Site 46 supports paint stripping activities as a probable source of contamination.

The lead screening identifed one surface soil sample location with a lead concentration greater than the residential soil cleanup target level (SCTL). Lead concentrations in soil samples submitted for synthetic precipitation leaching procedure (SPLP) extraction exceeded the groundwater cleanup target level (GCTL) for lead. Arsenic was reported in two soil samples at concentrations greater than the residential SCTL. Aluminum was reported in one soil characterization sample with a SPLP result greater than the NAS Pensacola reference concentration.

TCE was detected at two soil boring locations near the northeast corner of Building 72 at concentrations greater than the industrial SCTL and leaching SCTL. Two additional locations had trichloroethene (TCE) concentrations exceeding the leaching SCTL. Acetone and phenol were also detected at concentrations exceeding the leaching SCTL in one sample from this area.

TCE and vinyl chloride were detected at concentrations exceeding GCTLs in two of the existing Site 38 monitoring wells that were sampled for this investigation. The vinyl chloride concentrations also were greater than the marine surface water criteria. Naphthalene was detected in four of the groundwater

samples collected at Site 46, with the concentration in one monitoring well greater than the GCTL. This well was located in the area where previous investigations had noticed a petroleum odor.

Aluminum and iron were detected in deep monitoring wells at concentrations exceeding the GCTL and the NAS Pensacola reference concentration. Arsenic, cadmium, lead, and vanadium were each detected in one groundwater sample at concentrations greater than the GCTL. Manganese was detected in most of the groundwater samples collected at Site 46.

RISK ASSESSMENT

The human health risk assessment indicated carcinogenic and non-carcinogenic risks for the hypothetical future resident for soil and groundwater. In soil, the primary driver of risk is TCE; in groundwater, the primary drivers of risk are CVOCs and arsenic.

The ecological risk assessment evaluated factors that affect potential exposures such as quality of the habitat, and potential use of the site by ecological receptors. Risk to soil invertebrates and plants from CVOCs and lead is low. However, this risk is lessened by the limited area of exposed soil available to soil invertebrates and plants. Potential risk from contaminants detected in groundwater is considered negligible.

CONCLUSIONS AND RECOMMENDATIONS

The area at the northeast corner of Building 72 where TCE and other CVOCs were detected in surface soil and subsurface soil samples will require active remediation to prevent further impact to site groundwater.

Metals and CVOCs in groundwater at Site 46 exceeded risk-based screening criteria. The proposed plan for remediation at Site 38 has established that natural attenuation of metals and CVOCs is sufficently protective of human health and the environment. Because the groundwater contaminants and concentrations for Site 46 are similar to those of Site 38, a similar remedial approach, monitored natural attenuation, should be considered for Site 46. A detailed evaluation of alternatives to achieve this goal should be presented in a Feasibility Study for Site 46.

1.0 INTRODUCTION

Tetra Tech NUS, Inc., (TtNUS), under contract to the Department of Navy, Naval Facilities Engineering Command, Southeast (NAVFAC SE) is submitting this Remedial Investigation (RI) Report documenting the investigation at Installation Restoration (IR) Site 46 (Former Building 72) at Naval Air Station (NAS) Pensacola, Florida. This RI was prepared under the Comprehensive Long-term Environmental Action Navy (CLEAN) III Contract Number N62467-94-D-0888, Contract Task Order (CTO) 0367.

1.1 PURPOSE OF INVESTIGATION

The primary objective of the RI is to provide data to evaluate the current environmental conditions and guide the selection of a remedy that is protective of human health and the environment for any contamination present at Site 46. In order to achieve this primary objective, samples from various media were collected and analyzed to evaluate the nature and extent at the site.

1.2 FACILITY BACKGROUND

NAS Pensacola (Figure 1-1) is located in Escambia County, in Florida's northwest coastal area, west of the city of Pensacola. The federal government established the Navy Yard at Pensacola in 1825. The Navy Yard was placed in caretaker status in 1911. Naval aviation operations began at the facility in 1914. The facility was expanded in 1930's as a NAS.

Current land use at NAS Pensacola consists of areas used for flight operations at Forrest Sherman Field, various military housing, training, support activities, and historical facilities open to the public including Gulf Islands National Seashore and the National Museum of Naval Aviation. Additional details on the NAS Pensacola facility may be found in the facility administrative record.

Site 46 is located in the southeastern portion of the facility, immediately north of and adjacent to the NAS Pensacola waterfront on Pensacola Bay (Figure 1-1).

1.2.1 Site Description and History

Site 46 is located in the southeastern portion of NAS Pensacola and includes the area south of the former location of Building 1 (Figure 1-2). The site is located approximately 90 feet to the west of the Former Building 71 footprint, where the RI for IR Site 38 was conducted (EnSafe, 1998). The site is bordered by Pensacola Bay to the immediate south, and is separated from the Bay by a concrete seawall. The area has recently been used for vehicle parking by Morale, Welfare and Recreation (MWR) and temporary boat storage by Port Operations.

Buildings 71 and 72 were constructed in the early 1920's and were steel-framed structures with metal roofs approximately 100 feet wide by 160 feet long (Figure 1-2). Prior to 1935, these buildings were sea plane hangars used for aircraft storage and maintenance. From 1935 up to the late 1970's the buildings were used for aircraft paint stripping and painting. Both buildings were demolished in mid-1993.

An estimated 400 gallons per day (gpd) of acrylic and epoxy paint stripper and another 400 gpd of ketone were used at these buildings during paint stripping operations. Other chemicals, including phenols and TCE, may have been used at the site. A series of interconnected drainage trenches in the floors of Building 72 and Building 71 (Figure 1-3) were used to collect waste solvent used in the stripping operations (EnSafe, 1998). Prior to construction of the Industrial Wastewater Treatment plant (IWTP) in 1973, these trenches drained directly to Pensacola Bay from the southern end of each building (NEESA, 1983). The surface water and sediments in Pensacola Bay immediately south of Buildings 71 and 72 were designated as Site 2 and investigated as an RI. After 1973, the trenches were connected to the IWTP sewer line south of the buildings. When the buildings were demolished, the drainage trenches inside the buildings were filled with concrete (EnSafe, 1998).

1.2.2 Environmental Investigations in the Vicinity of Site 46

Previous investigations in the vicinity of Site 46 consisted of the completion of an RI at adjacent IR Site 38 (Former Building 71). The Site 38 RI included supplemental soil and groundwater sampling in a portion of what is now included in Site 46. The investigation of Site 38 was conducted as four events:

- 1994 RI, including soil and groundwater sampling (Ensafe, 1998).
- 1998 Supplemental Groundwater Sampling Event, including installation of additional monitoring wells in the Building 72 area (Ensafe, 1999).
- 1999 Groundwater Sampling Event in the Building 71 and 72 area, including installation of additional monitoring wells in the Building 72 area (Ensafe, 1999).
- 2000 Groundwater Sampling Event in the Building 71 area (Ensafe, 2001).

The RI Report for Site 38 (the area in and around former Building 71) indicated that parameters detected above screening levels in soil included metals, SVOCs, polynuclear aroamtic hydrocarbons (PAHs), pesticides, PCBs, and VOCs. The primar areas of soil contamination were centered beneath the Building 71 footprint. Parameters detected above screening levels in groundwater included metals, SVOCs, and VOCs, and were consistent with the soil contamination.

FORM CADD NO. SDIV-BH.DWG - REV 1 - 9/10/98

Much of the groundwater contamination was centered underneath the Building 71 footprint. Because of the detection of lead above screening levels in groundwater samples from monitoring wells west of the Building 71 footprint, supplemental groundwater sampling was conducted in 1998 to complete delineation of lead in groundwater. The results of the 1998 Supplemental Groundwater Sampling Event in the former Building 72 area indicated that lead concentrations had decreased approximately 50 percent in the Building 71 area since the RI sampling event (EnSafe, 1999). Groundwater samples from two additional monitoring wells located north of and centered in the Building 72 area were reported to contain lead concentrations exceeding screening levels.

Based on the results of this supplemental sampling (EnSafe, 1999), several new monitoring wells were installed to the west of Building 71, in the Building 72 area. These monitoring wells were sampled in 1999, along with several existing monitoring wells in the Building 71 area. Results from this sampling event indicated that lead in shallow groundwater in the Building 72 area increased in concentration towards the west across the site, and that lead in shallow groundwater underneath the former Building 72 had increased between the sampling events in 1998 and 1999. Groundwater data collected for the 1999 Groundwater Sampling Event (EnSafe, 1999) indicated that lead concentrations above screening levels in shallow groundwater in the former Building 72 area was not fully delineated. Additionally, the sample from one of the shallow wells located immediately south of former Building 72 emitted a strong petroleum odor. A second confirmatory sample from this well contained methylene chloride, TCE, and naphthalene above screening levels. These results prompted the Navy to designate the former Building 72 area as a separate IR site.

Groundwater sampling in the former Building 71 area was again conducted in 2000 to identify trends in lead concentrations (EnSafe, 2001). Groundwater data collected for the 2000 Groundwater Sampling Event (EnSafe, 2001) indicated that chlorinated solvent concentrations were slightly above or at screening levels in groundwater samples from monitoring wells located between former Buildings 71 and 72. Lead was not detected above its screening level in the groundwater samples from the former Building 71 area monitoring wells. The observed decrease in lead concentrations since the RI sampling in 1994 was attributed to sulfate-reducing conditions in the aquifer that may have caused the precipitation of dissolved lead as immobile lead sulfide.

This sampling event indicated that lead concentrations were drastically reduced in shallow groundwater compared to previous sampling events, and the report concluded that the attenuation in lead concentrations was naturally occurring (EnSafe, 2004). Under the IR program, soil and groundwater contamination in the former Building 71 area are being addressed by the remedy for Site 38, and impacts to soil and/or groundwater at Site 46 (former Building 72) are being addressed by this investigation (EnSafe, 2004).

Site 38 soil and groundwater sampling results were compared to the Florida SCTLs and Florida GCTLs in the Focused Feasibility Study (FS) (EnSafe, 2004). Constituents that exceeded residential SCTLs in surface soil included arsenic, chromium, copper, vanadium, Arochlor 1254, benzo(a)pyrene, and dibenz(a,h)anthracene. Constituents that exceeded leachability SCTLs in surface soil included chromium, cadmium, TCE, tetracloroethene (PCE), phenol, chloroform, 1,2-dichloroethane (DCA), 2-methylphenol, and 4-methylphenol. Constituents that exceeded leachability SCTLs in subsurface soil included chromium, TCE, PCE, chloroform, 1,2-DCA, phenol, and 4-methylphenol.

Inorganic constituents exceeding GCTLs or background in shallow groundwater included aluminum, iron, lead, manganese, antimony, cadmium, chromium, and vanadium. SVOCs and PAHs exceeding GCTLs in shallow groundwater included naphthalene, bis(2-ethyhexyl)phthalate, 1,2,4-trimethylbenzene, and 1,3,5-trimethylbenzene. VOCs exceeding GCTLs in shallow groundwater included chloroethane, vinyl chloride, benzene, TCE, PCE, chloroform, 1,1,1-trichloroethane (TCA), 1,1-DCA, and 1,1-dichloroethene (DCE).

The FS concluded that the decrease in lead concentrations was the result of natural attenuation, and that geochemical conditions within the shallow groundwater were such that natural attenuation could also be expected to reduce organic parameters. The recommended remedy for Site 38 was monitored natural attenuation, and implementation of institutional controls to restrict potential receptor exposure to site soil and groundwater (EnSafe, 2004).

1.2.3 Regulatory Setting

The Navy IR Program was designed to identify and abate or control contaminant migration resulting from past operations at naval installations, with the goal of expediting and improving environmental response actions while protecting human health and the environment. The IR program is conducted in accordance with Section 120 of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980 as amended by the Superfund Amendments and Reauthorization Act (SARA) of 1986 and Executive Order 12580. CERCLA requires that federal facilities comply with the act, both procedurally and substantively. Site 46 is being investigated as part of CERCLA requirements.

1.3 REPORT ORGANIZATION

This RI Report is organized into eight sections with supporting references and appendices:

- Section 1.0 – Introduction
- Section 2.0 – Study Area Investigation
- Section 3.0 – Physical Characteristics of the Study Area
- Section 4.0 – Nature and Extent of Contamination

- Section 5.0 – Contaminant Fate and Transport
- Section 6.0 – Human Health Risk Assessment
- Section 7.0 – Ecological Risk Assessment
- Section 8.0 – Summary and Conclusions
- References
- Appendices - Supporting data and discussions

2.0 STUDY AREA INVESTIGATION

The primary objective of this RI is to provide data to evaluate the current environmental conditions and guide the selection of a remedy that is protective of human health and the environment for any contamination present at Site 46. Soil screening samples were collected for rush laboratory metals analysis and field headspace screening to provide a preliminary evaluation of site conditions and potential releases. Selection of soil characterization sample locations and additional monitoring well locations were based on the results of the soil screening investigation. Characterization soil and groundwater samples were collected for full suite of analyses to evaluate the occurrence of contaminants other than metals or VOCs at the site. The analytical results were compared to appropriate federal and state screening values. Field activities, such as sampling and monitoring well installation, were conducted in accordance with the Health and Safety Plan (HASP) and the FDEP Standard Operating Procedures (SOPs) for Field Activities (FDEP, 2004).

2.1 SOIL SCREENING

Twenty-eight soil borings were advanced to collect soil samples for lead screening (Figure 2-1). The soil samples were submitted to an offsite laboratory for rush lead, iron, and aluminum analysis. Lead data were collected based on the findings of the Site 38 RI, which identified elevated lead concentrations in soil in the Building 72 area. Iron and aluminum data were collected to evaluate the overall level of metals in site soils and to aid in identifying locations where lead concentrations were elevated in relation to the concentration trends for other metals.

The rationale for selecting soil boring locations was:

- One location, soil boring 46SB01, was targeted to investigate the former industrial waste sewer line and discharge line to Pensacola Bay on the south side of Building 72. Originally, four soil borings were planned for this area; however, erosion due to Hurricane Ivan had washed out much of this area, therefore only soil boring 46SB01 was advanced.
- Two soil boring locations, 46SB02 and 46SB03, targeted an area of organic and inorganic exceedances in soil located at the southeast corner of Site 46 noted during the Site 38 investigation.
- One location, soil boring 46SB10 targeted the area that had the highest lead detection in shallow groundwater in the Building 72 area during the Site 38 investigation.

P:\GIS\PENSACOLA_NAS\MAPDOCS\APR\SITE44_45_46.APR SB LOCATION SITE 46 LAYOUT 12/04/06 SS

- Eleven locations, 46SB18 through 46SB28 were targeted to investigate the former drainage trenches within Building 72.
- The remaining 13 locations were spaced evenly across the investigation area.

Soil screening samples were collected at each location from ground surface (below any pavement if present) to the saturated zone of the shallow aquifer. Depth to groundwater at the site ranged from 2 to 4 feet below land surface (bls). Because metals (particularily lead) may have been released at the ground surface, per the requirements of Chapter 62-780 FAC the soil screening samples were collected from the following depth intervals:

- Ground surface to 6 inches (immediately below surface pavement and sub-base where present)
- 6 inches to 2 feet
- 2 feet to 3 or 4 feet (if the soil was dry)

Soil samples were collected from each interval for field headspace screening using a photoionization detector (PID) with a 10.6 electron volt (eV) lamp. Field headspace screening was conducted following the FDEP SOP for soil headspace analysis. Soil boring logs are included in Appendix A.

2.2 CHARACTERIZATION SOIL SAMPLING

Following the lead screening, additional soil sampling was conducted to further characterize the nature of potential contaminants at the site. Three locations for characterization soil sampling were selected (Figure 2-1):

- Soil boring 46SB29 (adjacent to the 46SB25 screening soil boring location) on the northeast corner of the foundation of former Building 72. This location was reported to contain an elevated headspace screening response.

- Soil boring 46SB30 (adjacent to soil boring 46SB02) near the southwest corner of the Building 71 foundation. This location was also reported to contain an elevated headspace screening response.

- Soil boring 46SB31 (adjacent to soil boring 46SB21) at the southern edge of the Building 72 foundation. This location had the highest lead detection in the soil samples collected for metals screening.

The additional soil samples collected during the site characterization phase were analyzed for Target Compound List (TCL) and Target Analyte List (TAL) analytes, as well as petroleum hydrocarbons. The soil samples were analyzed for TCL VOCs [United States Environmental Protection Agency (USEPA) Method SW-846 8260B] and ethylene dibromide (EDB) (USEPA Method 504.1), TCL SVOCs and PAHs (USEPA Method SW-846 8270C/8310), TCL pesticides and PCBs (USEPA Method SW-846 8081/8082), TRPH [Florida Petroleum Range Organics (FL-PRO)] and TAL inorganics (USEPA Method SW 846 6010B, 9010, and 7471).

Characterization soil samples were collected from these locations for SPLP extraction and analysis for TCL VOCs and TAL inorganics. The SPLP sampling targeted chlorinated volatile organic compounds (CVOCs) previously identified in groundwater samples collected during the Site 38 investigations included TCE and PCE. In addition, some of the metals previously detected during the Site 38 investigation, particularily lead, do not have default leaching SCTLs and site-specific testing is required to determine if site soils may leach these elements to groundwater.

2.3 CVOC DELINEATION

Additional soil borings were advanced at Site 46 as a separate mobilization based on the characterization soil sampling results. An area near the northeast corner of the former Building 72 foundation (Figure 2-1) at soil boring 46SB29 was identified where CVOC concentrations exceeded Florida SCTLs. Ten soil boring locations were initially selected for CVOC delineation sampling (Figure 2-1). One soil sample per each soil boring location was sent for quick turnaround analysis. The remaining samples were sent for standard turn around analysis. After evaluation of the quick turnaround sample data, three additional soil boring locations were sampled. The soil samples collected for this phase of the investigation were analyzed for a selected list CVOCs.

2.4 EXISTING WELL EVALUATION

A monitoring well network was previously installed at the site during the Site 38 investigation (Figure 2-2). Exisiting wells at the site are identified with 38 in the well designation. A map showing the locations of Site 38 monitoring wells in the vicinity of Buildings 71 and 72 are included in Appendix B. A summary of the well construction details are provided in Table 2-1. The existing monitoring wells were evaluated to determine if the wells were viable for current and future groundwater monitoring activities. Static water levels and total depths were recorded for each of the exisiting wells to determine if the wells were screened at appropriate intervals and if the wells had silted up or had become obstructed over time. Based on these observations, six monitoring wells installed previously for the Site 38 investigation were included in the Site 46 groundwater program, PEN-38GS01, PEN-38GI01, PEN-38GS03, PEN-38GI03, PEN-38GS05, and PEN-38GS13 (Figure 2-2). These wells are located at the western edge of Site 38,

west of former Building 71. Other Site 38 wells located in the Building 71 footprint or to the east of Building 71 were not included in the Site 46 investigation.

2.5 MONITORING WELL INSTALLATION

The monitoring wells installed at Site 46 were designed to investigate the aquifer interval from the water table down to a low-permeability confining unit, which is typically encountered from 50 to 75 feet bls at NAS Pensacola (Geraghty and Miller, 1986). During the investigation at Site 46, this confining unit was encountered at depths from 44 to 50 feet bls. Material above this low-permeabililty unit comprises the uppermost portion of the surficial aquifer, and is composed of quartz sand with generally small percentages of humic material, shell material, and heavy minerals. The groundwater investigation at Site 46 assessed the uppermost interval of the shallow surficial aquifer (bracketing the water table) and the lower interval of the surficial aquifer (immediately above the low-permeability unit). These units will be referred to as the “shallow” and “deep” aquifer intervals, respectively in this report.

The RI at Site 46 included the installation of monitoring wells targeting both the shallow and deep intervals, and sampling of both existing and newly-installed wells (Figure 2-2). Twelve shallow monitoring wells were installed to an approximate depth of 13 feet bls. Eight deep monitoring wells were installed to depths ranging from 44 to 50 feet bls. Well construction details are provided in Table 2-1 and Appendix A.

The shallow monitoring wells were installed using hollow stem auger drilling methods and the deep wells were installed using sonic drilling methods. The monitoring wells were constructed using 2-inch diameter PVC screens (10 feet in length, and .010-inch factory slotted) and 2-inch diameter PVC risers. The monitoring wells were installed and constructed in accordance with NAVFAC SE and FDEP guidance documents. Following well installation, the top-of-casing elevations for the new wells were surveyed using the top-of-casing elevation of PEN-38GS01 as a benchmark with an elevation of 5.70 feet (EnSafe, 1998).

2.6 GROUNDWATER SAMPLING

Groundwater samples were collected from the existing and the newly installed monitoring wells to assess the current groundwater conditions. Sixteen shallow monitoring wells, two intermediate monitoring wells, and eight deep monitoring wells were sampled for the RI. The well locations are shown on Figure 2-2.

The wells were purged and sampled using a peristaltic pump and low-flow quiescent purging technique. Groundwater sampling was conducted during December 2005. The monitoring wells were purged in accordance with FDEP SOP FS 2212, Well Purging Techniques (FDEP, 2004). Groundwater samples

were collected in accordance with FDEP SOP FS 2220, Groundwater Sampling Techniques (FDEP, 2004). Static water levels and total well depths were measured on December 6 and December 21, 2005. Water level and groundwater sampling records are in Appendix A.

The groundwater samples collected during the RI were analyzed for TCL and TAL analytes, as well as petroleum hydrocarbons. The groundwater samples were analyzed for Contract Laboratory Program (CLP) TCL VOCs (USEPA Method SW-846 8260B) and EDB (USEPA Method 504.1), TCL SVOCs and PAHs (USEPA Method SW-846 8270C/8310), TCL pesticides and PCBs (USEPA Method SW-846 8081/8082), TRPH (FL-PRO) and TAL inorganics (USEPA Method SW 846 6010B, 9010, and 7471).

2.7 AQUIFER CHARACTERIZATION

Static water level (SWL) measurement data were recorded from Site 46 monitoring wells on December 6 and December 21, 2006. The SWL measurement data and the elevations from the well top-of-casings were used to determine the groundwater elevation at each monitoring well.

Slug tests were conducted in three shallow monitoring wells and three deep monitoring wells at Site 46. Each test was performed by displacing a volume of water with a PVC rod of known volume and recording the recharge rate of the displaced water in the monitoring well. The recharge rate was recorded using an electronic data logger and pressure transducer. Both rising head and falling head slug tests were conducted in each monitoring well.

Calculations were performed using the Aqtesolv™ aquifer characterization program. The Bouwer and Rice and the Hvorslev solutions were calculated for each of the slug tests. Slug test data and calculations used to determine hydraulic conductivity are included in Appendix C.

The geometric means of the slug test results for the shallow zone and the deep zone were calculated for each type of test (rising head/falling head) and each analytical method (Bouwer and Rice/Hvorslev). The geometric mean of these results was used to represent the average hydraulic conductivity for each of the aquifer zones.

Specific capacity analyses were calculated for two shallow wells and three deep wells at Site 46 using data recorded during well development. Pumping rate, drawdown from static, and pumping time were used to calculate hydraulic conductivity. The hydraulic conductivity values calculated using the specific capacity method were compared to the values from the slug test analyses.

3.0 PHYSICAL CHARACTERISTICS OF THE STUDY AREA

Data to evaluate site conditions and characteristics were obtained from available literature and the site-specific investigations.

3.1 SURFACE FEATURES

NAS Pensacola is located in the extreme southeastern portion of Escambia County, Florida, which lies within the Coastal Plain Province of the United States. As described in the Initial Assessment of NAS Pensacola (NEESA, 1983), NAS Pensacola lies within the coastal lowland that is characterized by a series of broad, nearly level marine terraces that extend several miles from the coast and merge with the narrow terraces along the Escambia and Perdido Rivers. NAS Pensacola is located on a peninsula with gently sloping terrain. The land surface elevations on the peninsula range from sea level to approximately 40 feet above mean sea level.

Site 46 is located between Pensacola Bay to the south and Radford Boulevard to the north (Figure 3-1). The parking area between Radford Boulevard and the former location of Building 1 to the north was investigated as a possible source area for Site 46 contaminants. IR Site 45 is located on the north side of former Building 1. The area covers approximately 300,000 square feet (7 acres) and the site elevation is approximately 4 to 7 feet above mean sea level. There is little vertical relief in the concrete paved areas of the site.

3.2 METEOROLOGY

Escambia County has a warm, humid-temperate climate [United States Department of Agriculture (USDA) 2004]. Along the coast, the Gulf of Mexico moderates high temperatures in the summer and low temperatures in the winter. Total annual precipitation is about 62 inches. The greatest amount of rain falls in July and August. Occasionally, short droughts occur in late spring.

3.3 SURFACE WATER HYDROLOGY

NAS Pensacola is bordered on the south by Big Lagoon, on the south and east by Pensacola Bay, and on the north by Bayou Grande (NEESA, 1983). Sandy surface soil in this area allows for a high proportion of rainfall to infiltrate into the ground and consequently there are few streams. The surface topography has little dissection and the natural drainage system is poorly developed. Much of the surface drainage has been constructed or modified to accommodate structures on base. Swampy areas exist at or near the western portion of NAS Pensacola, and man-made drainage ways and storm drains feed into the short intermittent streams emptying in to Pensacola Bay and Bayou Grande. No perennial

streams enter or exit NAS Pensacola, but the marshy areas and three small lakes on the golf course are persistent throughout the year.

Surface water features are not present at Site 46 and runoff from the paved areas is directed into the storm water sewer system along Radford Boulevard or into Pensacola Bay. Pensacola Bay is adjacent to the southern edge of Site 46. An intermittant stream is located approximately 1 mile to the northwest of the site is the nearest non-marine surface water body. This intermittant stream drains to Bayou Grande approximately 1¾ mile to the north of the site.

3.4 GEOLOGY

The surficial geology of the area consists of Pleistocene marine deposits made up of light brown to tan, fine quartz sand with associated stringers and lenses of gravel and clay. Underlying these deposits, increasing with age, are the Citronelle Formation, the Miocene Coarse Clastics, the Pensacola Clay, the Tampa Formation, the Chickasawhay Limestone, the Bucatunna Clay member of the Byram Formation, the Ocala Group, the Lisbon equivalent, the Tallahatta Formation, and the Hatchetigbee Formation. The Pleistocene deposits and Citronelle formation are often impossible to differentiate, and together range in thickness from approximately 30 feet to 800 feet across the county (NEESA, 1983).

The lithologies observed during drilling of Site 46 monitoring wells are typical of the undifferentiated Pleistocene marine deposits. The ground surface to 1 foot interval at most of the sampling locations showed signs of disturbance either grading and filling or pavement construction. Below 2 feet, typical lithologies included sand ranging from white or tan to dark brown in color. Significant clay or gravel horizons were not encountered. Boring logs are included in Appendix A.

3.5 SOILS

Soils from the developed areas at Site 46 are classified as urban land, which are typical of industrial areas (USDA, 2004). The native soils usually have been altered by grading or fill and the ground surfaces have been paved or built upon.

3.6 GROUNDWATER HYDROLOGY

3.6.1 Regional Hydrology

Groundwater in Escambia county occurs in three major aquifers: a shallow aquifer which is both artesian and nonartesian (the sand and gravel aquifer), and two deep artesian aquifers (the upper and lower limestones of the Floridan Aquifer). In the southern half of the area, the sand and gravel aquifer and the

upper limestone of the Floridan aquifer are separated by a thick section of relatively impermeable clay; but, in the northern half the sand and gravel aquifer and the upper limestone of the Floridan aquifer are in contact with one another. The upper limestone of the Floridan aquifer is separated from the lower limestone by a thick clay bed (NEESA, 1983).

The sand and gravel aquifer is composed of sand but has numerous lenses and layers of clay and gravel. The formation also contains lenses of hardpan where the sand has been cemented by iron oxide minerals. This aquifer lies at the surface throughout Escambia County. Logs of borings from various locations at NAS Pensacola show that the surficial sands extend from ground surface to a depth of approximately 35 feet mean sea level below which is a 15-foot thick marine clay, the continuity of which is uncertain. Underlying the clay is more sand with numerous clay lenses (Geraghty and Miller, 1986).

Water levels in the shallow aquifer range from 0 to approximately 30 feet bls across the NAS Pensacola area. The groundwater flow has historically been found toward the Gulf of Mexico and the Escambia and Perdido rivers although groundwater flow can vary locally due to the effect of topography or surface water bodies. The aquifer recharge is predominantly from local precipitation (Geraghty and Miller, 1986).

The shallow saturated permeable beds in the sand and gravel aquifer contain groundwater under nonartesian conditions, while the deeper permeable beds contain groundwater under artesian pressure, where they are confined by lenses of clay and sandy clay (NEESA, 1983).

Below the sand and gravel aquifer, the limestone layers comprise the regionally extensive Floridan aquifer, which in this area is divided into upper and lower units separated by the Bucatunna clay. The upper Floridan aquifer is an important source of water in areas east of Escambia County; however, in the Pensacola area it is highly mineralized and not used as a water supply. The lower Floridan aquifer is also highly mineralized and is designated for use as an injection zone for waste disposal in this area (Geraghty and Miller, 1986).

3.6.2 Site-Specific Hydrology

Hydrogeologic data were collected to evaluate movement of groundwater in the shallow surficial aquifer at Site 46. Depth to groundwater and groundwater elevation were used to determine the site-specific groundwater flow direction and gradient. Groundwater flow velocity at the site was estimated using the hydraulic conductivity data collected at the site.

3.6.2.1 SWL and Groundwater Elevations

SWL measurement data were recorded from Site 46 monitoring wells on December 6 and December 21, 2006 (Table 3-1). The SWL measurement data and the elevations from the well top-of-casings were used to determine relative groundwater elevations at each well (Appendix A).

Monitoring wells installed at Site 46 are grouped by the subsurface interval of the well screen:

- Shallow Monitoring Wells Screened to up to 14 feet below bls, to bracket the water table.
- Deep Monitoring Wells Screened between 32 to 50 feet bls, above the top of the first confining layer (except monitoring well PEN-38GI01 screened from 17 to 27 feet).

On December 6, 2005, the groundwater elevations in the shallow monitoring wells ranged from 2.30 feet in monitoring well PEN-46-01 on the north side of the site to 0.39 feet in monitoring well PEN-38GS13 adjacent to Pensacola Bay. The groundwater elevations for deep wells ranged from 1.98 feet in monitoring well PEN-46-08, adjacent to Radford Boulevard to 0.47 feet in monitoring well PEN-38GI03, adjacent to Penscala Bay.

On December 21, 2005, the groundwater elevations in the shallow monitoring wells ranged from 2.30 feet in monitoring well PEN-46-01 on the north side of the site to 0.04 feet in monitoring well PEN-38GS13 adjacent to Pensacola Bay. The groundwater elevations for deep wells ranged from 1.87 feet in monitoring well PEN-46-02 in the northwest corner of the site to 0.28 feet in monitoring well PEN-38GI03, adjacent to Penscala Bay.

Groundwater elevations in the shallow monitoring wells ranged from 0.00 to 0.40 feet lower on December 21, 2005, than the elevations measured on December 6, 2005. The magnitude of change increased in shallow wells towards the south side of the site, suggesting that tidal variations influence groundwater levels closer to Pensacola Bay. Groundwater elevations in the deep monitoring wells were 0.00 to 0.21 feet lower on December 21, 2005, compared to December 6, 2005, suggesting a less strong tidal influence on the deep interval of the surficial aquifer.

3.6.2.2 Groundwater Flow Direction

To evaluate the direction of groundwater flow in the shallow and deep zones of the surficial aquifer, the groundwater elevations from the shallow and deep monitoring wells were plotted on site maps. Data from the shallow wells measured on December 6, 2005, and December 21, 2005, are plotted on Figure 3-2 and Figure 3-3. Data from the deep wells measured on December 6, 2005, and December 21, 2005, are

plotted on Figure 3-4 and Figure 3-5. Groundwater elevation isocontours were drawn from the plotted data.

Interpretation of data from Site 46 indicates that overall, groundwater flow at the water table and the deep surfical aquifer interval is to the south, towards Penscola Bay.

3.6.2.3 Groundwater Gradient

The average horizontal groundwater gradient in the shallow and deep zones of the surficial aquifer across the site was calculated from the groundwater elevations measured in monitoring wells from each zone and the estimated groundwater flow direction.

The groundwater flow gradient was determined using the following equation:

$$i = \frac{h_1 - h_2}{d}$$

Where:

i = the hydraulic gradient

h_1 = the water elevation at point 1, the highest value

h_2 = the water elevation at point 2, the lowest value

d = the horizontal distance between point 1 and point 2 parallel to the direction of groundwater flow

The highest and lowest groundwater elevation values measured in the monitoring wells from each aquifer zone (shallow and deep) were used to determine the difference in groundwater elevation across the site. The horizontal distance between the high and low groundwater elevation points was measured parallel to the estimated groundwater flow direction. The horizontal groundwater gradients are summarized in Table 3-2.

On December 6, 2005, the groundwater elevation in monitoring well PEN-46-01, 2.30 feet, was the highest value and the groundwater elevation in monitoring well PEN-38GS13, 0.39 feet, was the lowest value in the water table monitoring wells. The horizontal distance between these two wells parallel to groundwater flow was approximately 584 feet. These data indicate the average hydraulic gradient of 0.003 feet/foot for the water table wells.

On December 21, 2005, the groundwater elevation in monitoring well PEN-46-01, 2.30 feet, was the highest value and the groundwater elevation in monitoring well PEN-38GS13, 0.04 feet, was the lowest

value in the water table monitoring wells. The horizontal distance between these two wells parallel to groundwater flow was approximately 565 feet. These data indicate the average hydraulic gradient of 0.004 feet/foot for the water table wells.

On December 6, 2005, the groundwater elevation in monitoring well PEN-46-08, 1.98 feet, was the highest value and the groundwater elevation in monitoring well PEN-38GI03, 0.47 feet, was the lowest value in the intermediate and deep monitoring wells. The horizontal distance between these two wells parallel to groundwater flow was approximately 350 feet. These data indicate the average hydraulic gradient of 0.004 feet/foot for these wells.

On December 21, 2005, the groundwater elevation in monitoring well PEN-46-02, 1.87 feet, was the highest value and the groundwater elevation in monitoring well PEN-38GI03, 0.28 feet, was the lowest value in the intermediate and deep monitoring wells. The horizontal distance between these two wells parallel to groundwater flow was approximately 525 feet. These data indicate the average hydraulic gradient of 0.003 feet/foot for these wells.

The average horizontal gradient in both the shallow and deep intervals was 0.0035 feet/foot.

3.6.2.4 Vertical Gradient

The vertical groundwater gradient was estimated from the groundwater elevations measured in the shallow and deep monitoring well pairs installed at the site. The vertical gradient is determined from the difference in groundwater elevation in the adjacent shallow and deep monitoring wells and the vertical separation of the screened intervals of the monitoring wells. The vertical separation of each well cluster is the difference in depth below grade of the bottom of the shallow well screened interval and the bottom of the deep well screened interval. If the groundwater elevation in the shallow well in a cluster is higher than the groundwater elevation in the deep well, the vertical gradient is negative, or downward. If the groundwater elevation in the shallow well in a cluster is lower than the groundwater elevation in the deep well, the vertical gradient is positive, or upward. The vertical gradients are summarized in Table 3-3.

In general, the vertical gradients were upward in the area north of Radford Boulevard and in well clusters near Pensacola Bay. The vertical gradients were downward in the central part of the site around Radford Boulevard. This area has less pavement and more grass areas and the change in vertical gradient may indicate that infiltration and recharge are more prevalent in this part of the site.

3.6.2.5 Hydraulic Conductivity

Hydraulic conductivity values for Site 46 were estimated using data from slug tests and specific capacity data collected during well development conducted as part of the RI. The slug test results are summarized in Table 3-4 and the slug test data and test analyses are included in Appendix C The geometric mean of the hydraulic conductivity values reported for shallow wells at Site 46 is approximately 245 feet/day or 0.17 feet/minute. The geometric mean of the hydraulic conductivity values reported for the deep wells at Site 46 is approximately 16 feet/day or 0.011 feet/minute, which is an order of magnitude less than the shallow wells.

3.6.2.6 Groundwater Flow Velocity

Potential movement of groundwater by natural flow in the saturated zone can be estimated by Darcy's Law, which may be expressed as:

$$v = \frac{(K \times i)}{n}$$

Where:

v = average velocity

K = hydraulic conductivity

i = average hydraulic gradient

n = effective porosity

Data from soil borings advanced at Site 46 indicate that fine grained sand and silty sand are the typical lithologies at the site. Review of standard literature suggests that a representative effective porosity for this lithology is approximately 30 percent (Heath, 1983).

Using an average hydraulic conductivity of 245 feet/day, an average hydraulic gradient of 0.0035 feet/foot, and an effective porosity value of 30 percent, the estimated average groundwater velocity for the water table zone at Site 46 was calculated at 2.86 feet/day or about 1,044 feet/year.

Using an average hydraulic conductivity of 16 feet/day, an average hydraulic gradient of 0.0035 feet/foot, and an effective porosity value of 30 percent, the estimated average groundwater velocity for the deep zone at Site 46 was calculated at 0.19 feet/day or about 70 feet/year.

3.6.2.7 On Base Potable Water Supply Wells

Three water wells are located on NAS Pensacola to provide an emergency backup potable water supply (NEESA, 1984). The backup water supply wells are completed at depths ranging from 224 to 250 feet bls

and extract groundwater from the sand and gravel aquifer. The nearest potable water well to Site 46 is Well 1, located approximately 5,000 feet to the northwest. The main source of potable water for the base is the Navy-owned well field located at Naval Technical Training Center (NTTC) Corry Station, which is located approximately three miles north of NAS Pensacola on the north side of Bayou Grande.

3.7 DEMOGRAPHY AND LAND USE

NAS Pensacola is located west of the City of Pensacola, Florida, in southern Escambia County. NAS Pensacola is an active military facility. The primary mission of the facility is aviation training. Additional missions include tenant support and services to other activities in the region. Land uses on base include training activities, equipment and materials storage, maintenance areas, recreational facilities, and residential housing for military personnel. Land use in the off-base areas adjacent to NAS Pensacola is primarily residential.

Site 46 is located adjacent to Pensacola Bay and controlled public access is allowed, recreational users as well as site and maintenance workers are expected to use the site. Following Hurricane Ivan, a paved walk way was installed along the bayfront following removal of old pavement west of Building 73. Building 73 has been renovated for use by Port Operations. Other buildings in the area are used for administrative and training facilities.

3.8 ECOLOGY

Site 46 is located in a developed area of the base, adjacent to Pensacola Bay. Ground cover at the site is predominantly paved parkings areas or buildings. Site 46 is adjacent to Pensacola Bay (IR Site 2) and wildlife use Site 46 temporarily, but due to lack of suitable habitat, are unlikely to feed at Site 46.

A list of federally listed threatened and endangered species and species of special concern for Escambia County was obtained from the web site for the Ecological Services and Fisheries Resource Office of the U.S. Fish and Wildlife Service in Panama City, Florida and is included in Appendix B. Five fish, 12 amphibians/reptiles, 14 birds, 4 mammals, and 24 plants are listed as threatened, endangered, or a species of special concern for the county (Appendix B). Some of the habitats listed for these special status species (i.e., estuarine or marine) exist in adjacent areas, but do not exist at Site 46. Therefore, the special status species recorded in Escambia County would be expected at areas adjacent to the site.

4.0 NATURE AND EXTENT OF CONTAMINATION

The analytical results for soil and groundwater samples collected during this investigation were compared to appropriate cleanup target levels (CTLs) established by FDEP. Analytical summary tables and contaminant concentration maps are presented in the investigation results sections. Validation reports for the laboratory analytical results are included in Appendix D.

4.1 CONTAMINANT SOURCES

The release of contaminants at Site 46 appears to have resulted from waste disposal practices related to paint stripping and painting operations or undocumented minor spills. The source and nature of materials, as well as the time of release, are unknown.

4.2 SOILS AND VADOSE ZONE

To evaluate the nature and extent of contaminants at Site 46, the surface and subsurface soil analytical results were compared to the risk-based SCTLs established in 62-777, Florida Administrative Code (FAC) for direct exposure-residential, direct exposure-industrial, and leachability based on groundwater criteria, as well as the NAS Pensacola reference concentrations for metals in soil (EnSafe, 1994). The reference concentrations are facility-specific background concentrations established for NAS Pensacola (Appendix B).

4.2.1 Lead Screening

Soil screening samples were collected at 28 locations at Site 46 for metals analysis. The samples were analyzed for lead, iron, and aluminum. Lead data were collected based on the findings of the Site 38 RI, which identified lead concentrations exceeding screening criteria in soil in the Building 72 area. Iron and aluminum data were collected to evaluate the overall level of metals in site soils and to aid in identifying locations where lead concentrations were elevated in comparison to other metals. The lead screening results are summarized in Table 4-1. Data validation reports are included in Appendix D

Soil boring location 46SB21 was reported to contain the the only lead concentration that exceeded the SCTL screening criteria (Figure 4-1). The reported concentration, 619 milligrams per kilogram (mg/kg), was greater than the residential SCTL of 400 mg/kg. Lead concentrations in the other soil samples were less than the residential SCTL. Therefore, the 46SB21 location was selected for full suite site characterization sampling and analysis. Iron and aluminum concentrations in each of the samples analyzed were less than the residential SCTLs.

The soil screening samples were also field-screened for organic vapors using headspace methods. No areas of elevated headspace screening responses, specified as greater than 100 parts per million (ppm) in the Sampling and Analysis Plan (SAP) (TtNUS, 2005) were found. The headspace screening results are summarized in Table 4-2. The soil boring logs are included in Appendix A.

Headspace screening responses in vadose zone soil greater than 1 ppm were limited to the 46SB03, 46SB25, and 46SB26 locations (Figure 4-1). The highest recorded response, 14.4 ppm from 2 to 4 feet at 46SB26. Soil samples from soil borings 46SB03 and 46SB25 were selected for full suite site characterization sampling and analysis.

4.2.2 Site Characterization Soil Sampling

The characterization soil samples were collected at three soil boring locations at Site 46: 46SB03, 46SB21, and 46SB25. Three soil samples were collected from each of the boring locations at depths of 0-6 inches, 6 inches to 2 feet, and 2 feet to 4 feet. The characterization samples were analyzed for TCL VOCs, TCL SVOCs and PAHs, TCL pesticides and PCBs, and petroluem hydrocarbons, and TAL inorganics. The characterization samples were also submitted for SPLP extraction and analysis for TCL VOCs and TAL inorganics. One trip blank, one rinsate blank, and one field duplicate were collected for quality assurance/quality control (QA/QC) purposes. Data validation reports are included in Appendix D.

4.2.2.1 Metals

The soil samples collected for full suite analysis were analyzed for TAL inorganics. Table 4-3 summarizes the inorganic analytes detected in the characterization soil samples. Table 4-4 summarizes the analytical results for the SPLP samples.

Lead concentrations reported for the site characterization soil samples were less than the residential SCTL, including the characterization samples collected at the soil screening sample location where lead had been detected at a concentration greater than the residential SCTL (Figure 4-1). A default leaching SCTL has not been established for lead, therefore results of the SPLP extraction and analysis were compared to the GCTL for lead. The lead concentrations for soil samples extracted by SPLP and analyzed for metals were greater than the GCTL for lead [15 micrograms per liter (μg/L)] in the following samples:

- 46SB2902 41.2 μg/L
- 46SB2903 33.7 μg/L
- 46SB3001 57.4 μg/L
- 46SB3002 48.6 μg/L
- 46SB3003 259 μg/L
- 46SB3103 125 μg/L

N/C - No criteria established
Values in bold exceed screening criteria.
U - Analyte concentration less than the value shown.
J - Estimated concentration less than method quantitation limit.

Arsenic was detected in the two soil characterization samples at concentrations equal to or greater than the residential SCTL for arsenic, 2.1 mg/kg (Table 4-3):

- 46SB3101 2.1 mg/kg
- 46SB3102 2.4 mg/kg

A statistical analysis of the distribution of arsenic and iron in soil at NAS Pensacola was prepared in order to identify sites where arsenic concentrations were elevated due to site activities (Appendix B). Arsenic and iron data from 653 soil samples collected base-wide were evaluated and 55 of these soil samples were determined to be outliers enriched in arsenic relative to the iron concentration. None of the soil samples from Site 46 were in this outlier group that was enriched in arsenic. The statistical analysis indicated a range of background arsenic concentrations from 0.1 to 17.5 mg/kg in soils at NAS Pensacola, indicating that arsenic concentrations up to 17.5 mg/kg can be due to natural processes and not release of arsenic from site activities. The two arsenic concentrations reported in Site 46 soil samples that exceeded residential SCTLs (2.1 mg/kg and 2.4 mg/kg) are within this stastical analysis background range and are therefore not believed to be attributal to site related activities.

The soil boring 46SB31 characterization samples were collected adjacent to the 46SB02 soil screening location because of headspace screening responses. These soil borings are located at the boundary of Sites 38 and 46 (Figure 4-2). A default leaching SCTL has not been established for arsenic, therefore results of the SPLP extraction and analysis were compared to the GCTL for arsenic of 10 μg/L. The arsenic concentrations reported for all SPLP samples were less than the arsenic GCTL (Table 4-4).

Aluminum, chromium, cobalt, copper, iron, manganese, and zinc do not have default leaching to groundwater SCTLs. Chromium, copper, iron, manganese, and zinc were detected in SPLP results from one or more samples at concentrations less than the GCTLs and/or base-wide reference concentrations (Table 4-4).

Aluminum was reported in one soil characterization sample with a SPLP result greater than the GCTL of 200 μg/L and the reference concentration of 3,882 μg/L (Table 4-4). Aluminum was detected in the SPLP results for seven of the other eight characterization samples at concentrations ranging from 1,730 μg/L to 475 μg/L, which are greater than the GCTL, but less than the NAS Pensacola reference concentration.

Metals including antimony, arsenic, chromium, iron, lead, and sodium were reported in the rinsate blank collected during the soil sampling event (Table 4-5). The metals detections in the rinsate blank was below data validation action levels.

4.2.2.2 VOCs

The soil characterization samples collected for full suite analysis were analyzed for TCL VOCs. Table 4-5 summarizes the organic analytes detected in the characterization soil samples. Table 4-4 summarizes the analytical results for the SPLP samples.

TCE was detected in one of the characterization soil samples at a concentration greater than the industrial SCTL (Table 4-5). The reported TCE concentration in soil sample 46SB2901 (the characterization sample collected from 0 to 6 inches adjacent to the 46SB25 soil screening location) was estimated at 150,000 micrograms per kilogram (μg/kg), which is greater than the industrial SCTL of 9,300 μg/kg and the default leaching SCTL of 30 μg/kg. Soil sample 46SB2902, collected from 6 inches to 2 feet at this soil boring location, had an estimated TCE concentration of 74 μg/kg, which also exceeds the leaching SCTL. The SPLP results for samples 46SB2901 (4 μg/L), and 46SB2902 (13 μg/L), exceeded the GCTL for TCE of 3 μg/L. The reported concentrations of TCE in the other characterization samples collected at Site 46 were less than the SCTLs.

PCE was detected in three soil characterization samples, 46SB3101, 46SB3102, and 46SB3103 (the characterization samples collected at the 46SB02 soil screening location) at concentrations less than the SCTLs (Table 4-5). PCE concentrations were less than the standard laboratory detection limits in the other soil characterization samples collected at Site 46.

Acetone was detected in one of the characterization soil samples at a concentration greater than the leaching SCTL (Table 4-5). The reported acetone concentration in 46SB2901 (the characterization sample collected from 0 to 6 inches at the 46SB25 soil screening location) was estimated at 26,000 μg/kg, which is greater than the default leaching SCTL of 25,000 μg/kg. Acetone was not reported in the SPLP VOC results for the Site 46 soil characterization samples.

Chloroform, ethylbenzene, toluene, and total xylenes were reported in one or more of the SPLP VOC analyses of the soil characterization samples. The reported SPLP results were less than GCTLs for these compounds.

Acetone and 2-butanone were reported in the rinsate blank collected during the soil sampling event (Table 4-5). The acetone detection in the rinsate blank was below data validation action levels. 2-butanone was not detected in the soil samples. Volatile concentrations in the trip blank were less than the laboratory detection limits.

4.2.2.3 SVOCs

The soil samples collected for full suite analysis were analyzed for TCL SVOCs. Table 4-5 provides a summary of the organic analytes detected in the characterization soil samples. Analytical results for carcinogenic PAHs are discussed in the next section.

Phenol was detected in soil sample 46SB2901 (the characterization sample collected adjacent to the 46SB25 location) at an estimated concentration of 360 μg/kg, which exceeds the leaching to groundwater criteria of 50 μg/kg (Table 4-5). Phenol concentrations were less than the standard laboratory detection limits in the other soil characterization samples collected at Site 46. Phenol was reportedly used as a solvent at the site (NEESA, 1983).
Other SVOCs detected in soil samples collected at Site 46 at concentrations less than screening criteria included acenaphthylene, anthracene, benzo(g,h,i)perylene, di-N-butyl phthalate, fluoranthene, fluorene, 2-methylnaphthalene, naphthalene, phenanthrene, and pyrene.

Naphthalene and diethylphthalate were reported in the rinsate blank collected during the soil sampling event (Table 4-5). The naphthalene detection in the rinsate blank was below data validation action levels. Diethylpthalate was not detected in the soil samples.

4.2.2.4 Carcinogenic PAHs

The seven carcinogenic PAHs listed in 62-777, FAC are benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, chrysene, and indeno(1,2,3-CD)pyrene. The concentration of each carcinogenic PAH is converted to a benzo(a)pyrene equivalent concentration using a toxic equivalency factor (TEF). The TEFs for the carcinogenic PAHS are:

- Benzo(a)pyrene 1.0
- Benzo(a)anthracene 0.1
- Benzo(b)fluoranthene 0.1
- Benzo(k)fluoranthene 0.01
- Dibenzo(a,h)anthracene 1.0
- Chrysene 0.001
- Indeno(1,2,3-CD)pyrene 0.1

The benzo(a)pyrene equivalent concentrations of the detected carcinogenic PAHs are summed for each sample and the sum is compared to the direct exposure SCTLs established for benzo(a)pyrene in 62-777, FAC. Table 4-5 summarizes the positive detections of carcinogenic PAHs and the calculated benzo(a)pyrene equivalent concentrations.

One or more carcinogenic PAHs were detected in each of the soil samples collected at Site 46 at concentrations less than the screening criteria. Benzo(a)pyrene equivalent concentrations were less than the residential SCTL in the soil samples collected at Site 46.

4.2.2.5 PCBs

Aroclor-1260 was detected in the three soil characterization samples, 46SB3101, 46SB3102, and 46SB3103 (the characterization samples collected at the 46SB02 soil screening location) at concentrations less than the SCTLs for PCBs (Table 4-5). Pesticide and PCB concentrations were less than the standard laboratory detection limits in the other soil characterization samples collected at Site 46.

4.2.2.6 Petroleum Hydrocarbons

Total petroleum hydrocarbons (TPH) were detected in soil characterization sample 46SB3101 (the characterization sample collected from 0 to 6 inches at the 46SB02 soil screening location) at a concentration less than the SCTL for total recoverable petroleum hydrocarbon (TRPH) (Table 4-5). TRPH concentrations were less than the standard laboratory detection limits in the other soil characterization samples collected at Site 46.

TRPH was reported in the rinsate blank collected during the soil sampling event (Table 4-5). The TRPH detection in the rinsate blank was below data validation action levels.

4.2.3 CVOC Delineation

The site characterization sampling identified an area at the northeast corner of the former Building 72 foundation (the 46SB25 and 46SB29 soil boring locations) where TCE concentrations exceeded the industrial SCTL. Thirteen additional soil boring locations were sampled to delineate the extent of the TCE release (Figure 4-3). Three field duplicates and one trip blank were collected for QA/QC purposes. The soil samples collected for this phase of the investigation were analyzed for selected CVOCs.

TCE was detected in two of the delineation soil samples at a concentration greater than the industrial SCTL (Table 4-6). The reported TCE concentration in soil samples 46SB3301 (32,000 μg/kg) and 46SB3302 (26,000 μg/kg) were greater than the industrial SCTL of 9,300 μg/kg, residential SCTL of 6,400 μg/kg and the default leaching SCTL of 30 μg/kg. The soil sample collected from 2 to 4 feet at soil boring location 46SB3303 had a TCE concentration of 1,900 μg/kg, which exceeds the leaching SCTL. The following delineation samples also had TCE concentrations greater than the leaching SCTL:

Notes:
SCTL- Soil cleanup target level
ft - feet
ug/kg - micrograms per kilogram
Values in bold exceed screening criteria
U - Analyte concentration less than the value shown
J - Estimated concentration between laboratory detection limit and quantitation limit
NA- Not Analyzed

- 46SB3401 1,600 μg/kg
- 46SB3402 1,400 μg/kg
- 46SB3403 900 μg/kg
- 46SB4301 820 μg/kg

The reported concentrations of TCE in the other delineation samples collected at Site 46 were less than the SCTLs.

Other CVOCs exceeding leaching SCTLs in the delineation samples at the 46SB33 and 46SB34 soil boring locations included chloromethane, cis-1,2-DCE, methylene chloride, and PCE. Concentrations of these compounds were less than the direct exposure SCTLs. The analytical results of the CVOC delineation are summarized in Table 4-6.

Methylene chloride and TCE were reported in the trip blank collected during the CVOC delineation (Table 4-6). These detections were below data validation action levels.

4.2.4 Soil Investigation Summary

The lead screening identifed one surface soil sample location (46SB21) with a lead concentration greater than the residential SCTL. The lead concentration in the site characterization sample collected from the same interval in an adjacent soil boring (46SB30) was less than the residential SCTL. Lead concentrations in soil samples from three soil boring locations submitted for SPLP extraction did exceed the GCTL for lead.

Arsenic was reported in two soil samples at concentrations equal to or greater than the residential SCTL. However, as indicated earlier, the reported arsenic concentrations were within the background range determined by the facility-wide statistical analysis of arsenic and iron distribution at NAS Pensacola. Therefore, the the reported concentrations are not believed to be attributal to former site conditions. These samples were collected from a soil boring adjacent to the area investigated for IR Site 38.

Aluminum was reported in one soil characterization sample with a SPLP result greater than the NAS Pensacola reference concentration. Aluminum was detected in the SPLP results for seven other samples at concentrations greater than the GCTL, but less than the NAS Pensacola reference concentration.

TCE was detected at two soil boring locations near the northeast corner of Building 72 at concentrations greater than the industrial SCTL and leaching SCTL. Two additional locations had TCE concentrations exceeding the leaching SCTL.

Acetone and phenol were also detected at concentrations exceeding the leaching SCTL in one sample from this area.

4.3 GROUNDWATER

The groundwater samples collected during the RI were analyzed for the full list of TCL and TAL analytes, as well as petroleum hydrocarbons. Groundwater samples were collected from 26 monitoring wells. Sixteen of the wells were shallow wells screened at the water table. Ten of the wells were deep wells, screened between 30 and 50 feet. Groundwater analytical results were compared to the risk-based GCTLs established in 62-777, FAC and the NAS Pensacola reference concentrations for metals in groundwater (EnSafe, 1994). The reference concentrations are facility-specific background concentrations established for NAS Pensacola (Appendix B). Table 4-7 provides a summary of analytes detected in groundwater.

4.3.1 Organic Analytes

4.3.1.1 Volatile Organics

TCE was detected in the groundwater samples collected from four of the shallow monitoring wells at Site 46 (Table 4-7). TCE was detected in two monitoring wells at concentrations greater than the GCTL of 3 μg/L (Figure 4-4):

- 38GS03 11 μg/L
- 38GS13 17 μg/L

Vinyl chloride was also detected in these two monitoring wells at concentrations greater than the GCTL of 1 μg/L:

- 38GS03 4 μg/L
- 38GS13 3 μg/L

TCE was detected in two other groundwater samples collected from shallow monitoring wells (Table 4-7).at concentrations less than the GCTL of 3 μg/L (Figure 4-4):

- 38GS05 1 μg/L
- PEN-46-19 2 μg/L

P:\GIS\PENSACOLA_NAS\MAPDOCS\APR\SITE 46.APR SITE 46 TCE AND VC LAYOUT 12/14/06 SS

CVOC concentrations were less than standard laboratory detection limits in the groundwater sample collected from PEN-46-18, a shallow monitoring well located approximately 100 feet down gradient of the CVOCs in soil discussed in Section 4.2.3. TCE concentrations in the deep monitoring wells were less than standard laboratory detection limits.

Other VOCs, including acetone, bromodichloromethane, carbon disulfide, chlorodibromomethane, chloroform, chloromethane, 1,1-DCA, cis- and trans-1,2-DCE, ethylbenzene, PCE, toluene, and xylenes were detected groundwater samples at concentrations less than the GCTLs.

Chloromethane and toluene were reported in the rinsate blank collected during the groundwater sampling event (Table 4-7). These detections in the rinsate blank were below data validation action levels. Chloromethane was also detected in one of the three trip blanks at a concentration less than data validation action levels.

4.3.1.2 Semivolatile Organics and PAHs

Bis(2-ethylhexyl)phthalate was detected at a concentration greater than the GCTL in one groundwater sample, the field duplicate collected at PEN-46-14 (Table 4-3). The reported concentration in 46GW1401D was 64 μg/L, greater than the GCTL of 6 μg/L. The bis(2-ethylhexyl)phthalate concentration for the corresponding groundwater sample (46GW1401) was less than the laboratory detection limit. PEN-46-14 was resampled in May 2006 and the bis(2-ethylhexyl)phthalate result from that sampling event was less than the laboratory detection limit.

Naphthalene was detected at a concentration of 240 μg/L in the groundwater sample from PEN-46-19, exceeding the GCTL of 14 μg/L. This well was installed in the area where groundwater samples collected from temporary wells for the Site 38 RI were reported to have a petroleum odor.

Three other PAHs, 2 methylnaphthalene, acenaphthene, and fluorene, were detected in groundwater samples at concentrations less than the GCTLs.

Naphthalene was reported in the rinsate blank collected during the groundwater sampling event (Table 4-7). The naphthalene detection in the rinsate blank was below data validation action levels.

4.3.1.3 Pesticides

Alpha chlordane, gamma chlordane and gamma-BHC (lindane) detected at concentrations less than GCTLs in groundwater samples collected at Site 46.

4.3.1.4 Petroleum Hydrocarbons

TRPH was reported in seven of the monitoring wells sampled at Site 46 at concentrations less than the GCTL.

4.3.2 Metals

Twenty metals were detected in the groundwater samples collected at Site 46. Seven of the metals (aluminum, arsenic, cadmium, iron, lead, manganese, and vanadium) were detected in one or more samples at concentrations exceeding Florida GCTLs. The remaining metals (barium, beyrillium, calcium, chromium, cobalt, copper, magnesium, nickel, potassium, selenium, silver, sodium, and zinc) were all detected at concentrations less than the Florida GCTLs. Metals reported at concentrations greater than screening criteria are discussed below.

Metals including aluminum, calcium, magnesium, mercury, sodium, and zinc were reported in the rinsate blank collected during the groundwater sampling event (Table 4-5). The metals detected in the rinsate blank were below data validation action levels.

4.3.2.1 Aluminum

Aluminum was detected in eight of the groundwater samples collected at Site 46 (Table 4-8). The aluminum concentrations in four of these monitoring wells were greater than the GCTL of 200 μg/L and the NAS Pensacola reference aluminum concentration of 3,882 μg/L:

- PEN-46-04 3,920 μg/L
- PEN-46-10 4,670 J μg/L
- PEN-46-12 7,200 J μg/L
- PEN-46-16 16,600 J μg/L

The aluminum concentrations reported for the other four samples were less than NAS Pensacola reference aluminum concentration, but still greater than the GCTL of 200 μg/L:

- PEN-38GS01 528 μg/L
- PEN-38-GI03 477 μg/L
- PEN-46-02 2,430 J μg/L
- PEN-46-20 674/862 μg/L

Except for monitoring well PEN-38GS01, these exceedances occurred in monitoring wells screened in the deep surficial aquifer (Figure 4-5).

4.3.2.2 Arsenic

Arsenic was detected in 14 of the groundwater samples collected at Site 46 (Table 4-8). Arsenic was detected in one monitoring well (PEN-46-19) at a concentration greater (13.3 μg/L) than the GCTL of 10 μg/L.

4.3.2.3 Cadmium

Cadmium was detected in six of the groundwater samples collected at Site 46 (Table 4-8). Cadmium was detected in one monitoring well (PEN-38GS05) at a concentration greater (8.9 μg/L) than the GCTL of 5 μg/L.

This monitoring well is one of the existing wells from the Site 38 RI that was sampled for the Site 46 investigation (Figure 4-5).

4.3.2.4 Chromium

Chromium was detected in 12 of the groundwater samples collected at Site 46 (Table 4-8). Chromium was detected in one monitoring well (PEN-46-16) at a concentration (244 μg/L) greater than the GCTL of 100 μg/L.

4.3.2.5 Iron

Iron was detected in 11 of the groundwater samples collected at Site 46 (Table 4-8). The iron concentrations in seven of these monitoring wells were greater than the GCTL of 300 μg/L and the NAS Pensacola reference iron concentration 1,708 μg/L:

- PEN-38GI01 1,880 μg/L
- PEN-46-02 2,500 μg/L
- PEN-46-04 2,400 μg/L
- PEN-46-12 1,920 μg/L
- PEN-46-14 7,770/7,020 μg/L
- PEN-46-16 6,510 μg/L
- PEN-46-20 8,220/8,100 μg/L

The iron concentrations reported for the other four samples were less than NAS Pensacola reference iron concentration, but still greater than the GCTL:

- PEN-38GI03 517 μg/L
- PEN-46-08 916 μg/L
- PEN-46-10 1,170 μg/L
- PEN-46-15 570 μg/L

Except for monitoring well PEN-46-15, these exceedances occurred in monitoring wells screened in the deep surficial aquifer (Figure 4-5).

4.3.2.6 Lead

Lead was detected in 15 of the groundwater samples collected at Site 46 (Table 4-8). Lead was detected in one monitoring well (PEN-38GS01) at a concentration greater (237 µg/L) than the GCTL of 15 µg/L:

This monitoring well is one of the existing wells from the Site 38 RI that was sampled for the Site 46 investigation (Figure 4-5).

4.3.2.7 Manganese

Manganese was detected in 24 of the groundwater samples collected at Site 46 (Table 4-8). The manganese concentrations detected in these monitoring wells were greater than the GCTL of 50 µg/L and the NAS Pensacola reference iron concentration 22 µg/L:

- PEN-38GI01 231 µg/L
- PEN-38GS01 505 µg/L
- PEN-38GS03 86.2 µg/L
- PEN-46-11 50.5 µg/L
- PEN-46-13 50 µg/L
- PEN-46-14 70.6/63 µg/L
- PEN-46-16 61.9 µg/L
- PEN-46-19 61.3 µg/L
- PEN-46-20 104/104 µg/L

These exceedances occurred equally in monitoring wells screened in the shallow and the deep surficial aquifer (Figure 4-5).

4.3.2.8 Vanadium

Vanadium was detected in 10 of the groundwater samples collected at Site 46 (Table 4-8). The vanadium concentrations in five of these monitoring wells were greater than the GCTL of 49 µg/L, including:

- PEN-38GI03 165 µg/L
- PEN-46-10 72.5 µg/L
- PEN-46-12 67 µg/L
- PEN-46-16 377 µg/L
- PEN-46-20 104 µg/L

These exceedances occurred in monitoring wells screened in the deep surficial aquifer (Figure 4-5).

4.3.3 Comparison to Marine Surface Water Criteria

Analytical results from selected monitoring wells were also compared to the GCTLs for discharge to marine surface waters (Table 4-9 and Table 4-10). The selected wells are located on the south side of the site and are the closest wells to Pensacola Bay (Figure 4-6). The monitoring wells included were:

- PEN-38GS13
- PEN-38GI03
- PEN38GS03
- PEN-46-13
- PEN-46-14
- PEN-46-17
- PEN-46-19
- PEN-46-20

Vinyl chloride concentrations in two wells (PEN-38GS03 and PEN38GS13) exceeded the marine surface water criteria as well as the GCTL (Figure 4-6). These monitoring wells are previously installed wells from the Site 38 RI that were sampled for the Site 46 investigation.

The naphthalene concentration in one well (PEN-46-19) exceeded the marine surface water criteria as well as the GCTL (Figure 4-6).

The chromium concentration in one well (PEN-38GI03) exceeded the marine surface water criteria and reference concentration, but was less than the GCTL. This monitoring well is an existing well from the Site 38 RI that was sampled for the Site 46 investigation.

The copper concentration in PEN-46-20 exceeded the marine surface water criteria and reference concentration, but was less than the GCTL.

Iron concentrations in two wells (PEN-46-14 and PEN46-20) exceeded the marine surface water criteria as well as the GCTL (Figure 4-6).

Beryllium (PEN-46-20), nickel (PEN-46-14), and zinc (38GS03), were detected at concentrations greater than the marine surface water criteria, but less than the NAS Pensacola reference concentrations.

The area of Pensacola Bay adjacent to the southern edge of Site 46 was investigated as IR Site 2, due to the discharge of untreated waste from operations at Building 71 (IR Site 38) and Building 72 (Site 46) prior to 1973. The final ROD for Site 2 (Ensafe, 2005), indicated that no impact to surface water and limited impact to sediment had occurred. The No Action alternative was selected for surface water and sediment at Site 2.

4.3.4 Groundwater Investigation Summary

Groundwater samples collected at Site 46 were analyzed for the full suite of TCL organic and TAL inorganic analytes and petroleum hydrocarbons. Analytical results were screened against FDEP GCTLs for organics, inorganics, and NAS Pensacola reference concentrations for inorganics.

VOCs, SVOCs, and PAHs were reported in groundwater samples collected at Site 46. TCE and vinyl chloride were the only VOCs detected at concentrations exceeding GCTLs. Previously installed Site 38 monitoring wells 38GS03 (11 μg/L) and 38GS13 (17 μg/L) were reported to contain the elevated concentrations. The vinyl chloride concentrations were also greater than the marine surface water criteria of 2.4 μg/L. Naphthalene was detected in four of the groundwater samples collected at Site 46, with the concentration in one monitoring well greater than the GCTL. Bis(2-ethylhexyl)phthalate was detected at a concentration greater than the GCTL in one field duplicate sample. The well was resampled in May 2006 and the bis(2-ethylhexyl)phthalate result from that sampling event was less than the laboratory detection limit. Concentrations of pesticides, PCBs and TRPH were less than the laboratory detection limits.

A wide range of metals were reported in groundwater samples collected at Site 46. Arsenic (PEN-46-19), cadmium (38GS05), and lead (38GS01) were each detected in one shallow monitoring well at concentrations greater than their GCTLs. An exceedance of the chromium GCTL was detected in one deep monitoring well (PEN-46-16).

Manganese was detected in most of the groundwater samples collected at Site 46. The reported manganese concentrations in nine monitoring wells exceeded the manganese GCTL. These exceedances occurred equally in monitoring wells screened in the shallow and the deep surficial aquifer.

Aluminum, iron, and vanadium were detected in only deep monitoring wells at concentrations exceeding the screening criteria.

4.4 SURFACE WATER AND SEDIMENTS

Surface water and sediment samples were not collected for the RI at Site 46 because no surface water bodies are present within the boundaries of the site. The ground cover at the site is largely impermeable due to buildings and pavement.

The area of Pensacola Bay adjacent to the southern edge of Site 46 was investigated as IR Site 2, due to the discharge of untreated waste from operations at Building 71 (IR Site 38) and Building 72 (Site 46) prior to 1973. The final ROD for Site 2 (Ensafe, 2005), indicated that no impact to surface water and

limited impact to sediment had occurred. The No Action alternative was selected for surface water and sediment at Site 2.

4.5 AIR

Air samples were not collected for the RI because the concentrations of volatile contaminants previously detected in soil and groundwater were low. Air monitoring was conducted during the site investigation to identify potential exposure to higher concentrations of volatile contaminants; however, no elevated readings in the breathing zone were documented during site activities.

5.0 CONTAMINANT FATE AND TRANSPORT

The behavior of contaminants released into the environment, particularly the potential for a contaminant to migrate from the release area and persist in an environmental medium, can influence whether the release will result in an adverse human health or ecological effect. The fate and transport discussion for this report is limited to the groups of chemicals that were detected during the Site 46 sampling events at concentrations greater than the CTLs established by the State of Florida.

5.1 POTENTIAL ROUTES OF MIGRATION

The movement of contaminants in the environment will be controlled by certain properties of the contaminant and the availability of suitable pathways for contaminant movement.

5.1.1 Physical and Chemical Factors Affecting Contaminant Mobility

The following properties can be used to evaluate the potential environmental mobility and fate of site contaminants:

- Specific gravity
- Vapor pressure
- Water solubility
- Octanol/water partition coefficient
- Organic carbon partition coefficient
- Henry's Law constant
- Bioconcentration factor
- Mobility index

Table 5-1 presents the physical and chemical properties of the organic compounds detected at Site 46. The relative mobilities of metals as a function of environmental conditions are provided in Table 5-2.

5.1.1.1 Specific Gravity

Specific gravity is the ratio of the weight of a given volume of pure chemical at a specified temperature to the weight of the same volume of water at a given temperature. Specific gravity is used to determine whether a chemical will have a tendency to float or sink in water when present as a pure chemical or at very high concentrations. Non-aqueous phase chemicals with a specific gravity greater than 1 will tend to sink, and chemicals with a specific gravity less than 1 will tend to float. The groups of chemicals detected at Site 46, halogenated VOCs, PCBs, and PAHs generally have a specific gravity greater than 1.

5.1.1.2 Vapor Pressure

Vapor pressure provides an indication of the rate at which a chemical volatilizes from both soil and water. Chemicals with higher vapor pressures are expected to enter the atmosphere much more readily than chemicals with lower vapor pressures. Volatilization is a significant loss process for VOCs in surface water or surface soil and is of primary importance at environmental interfaces such as surface soil/air and surface water/air. Volatilization is not as important when evaluating contaminated groundwater and subsurface soils that are not exposed to the atmosphere. Vapor pressures for halogenated VOCs are typically one or more orders of magnitude higher than vapor pressures of phthalates, pesticides or PAHs and volatilization is not significant for metals other than mercury.

5.1.1.3 Water Solubility

The rate at which a chemical may be leached from a solid matrix (soil, waste deposit) by infiltrating precipitation is proportional to its water solubility. More soluble chemicals are more readily leached than less soluble chemicals. The water solubilities presented in Table 5-1 indicate that TCE is slightly more soluable than PAHs, which are not especially water soluble.

The solubility of inorganics is strongly influenced by their valence state(s) and forms (hydroxides, oxides, carbonates, etc.). The solubility is also dependent on pH, Eh (redox potential), temperature, and other ionic species in solution (the Debye-Huckel theory). The solubility products reported in the literature vary with the type of complex formed, but generally it can be noted that, for example, cadmium and copper complexes are more soluble than lead and nickel complexes.

5.1.1.4 Octanol/Water Partition Coefficient

The octanol/water partition coefficient (K_{ow}) is a measure of the equilibrium partitioning of chemicals between octanol and water. A linear relationship between the K_{ow} and the uptake of chemicals by fatty tissues of animal and human receptors (the bioconcentration factor) has been established. It is also useful in characterizing the sorption of compounds by organic soils where experimental values are not available. PAHs are more likely to partition to fatty tissues than the more soluble VOCs. The K_{ow} is also used to estimate bioconcentration factors in aquatic organisms.

5.1.1.5 Organic Carbon Partition Coefficient

The organic carbon partition coefficient (K_{oc}) indicates the tendency of a chemical to adhere to soil particles containing organic carbon. Chemicals with high K_{oc}s generally have low water solubilities and vice versa. This parameter may be used to infer the relative rates at which the more mobile chemicals

(ketones, monocyclic aromatics, and halogenated aliphatics) partition to groundwater. Most PAHs are relatively immobile in the soil and are preferentially bound to the soil. These compounds are not as likely to be transported in the dissolved phase by groundwater to the same extent as compounds with higher water solubilities. However, these preferentially bound chemicals are easily transported by erosional processes when they are present in surface soils and the soil particles to which they have adsorbed are mobilized.

5.1.1.6 Henry's Law Constant

Both the vapor pressure and the water solubility are of use in determining volatilization rates from surface water bodies and from groundwater. The ratio of these two parameters, the Henry's Law constant, is used to calculate the equilibrium chemical concentrations in the vapor (air) phase versus the liquid (water) phase for the dilute solutions commonly encountered in environmental settings. In general, chemicals having a Henry's Law constant of less than 1×10^{-5} atm-m^3/mole should volatilize very little and be present only in minute amounts in the atmosphere or soil gas. For chemicals with a Henry's Law constant greater than 5×10^{-3} atm-m^3/mole volatilization and diffusion in soil gas could be significant.

5.1.1.7 Bioconcentration Factor

The bioconcentration factor (BCF) represents the ratio of aquatic-animal-tissue concentration to water concentration. The ratio is both contaminant and species specific. When site-specific values are not measured, literature values are used or the BCF is derived from the octanol/water coefficient. Many of the PAHs will bioconcentrate at levels three to five orders of magnitude greater than those concentrations found in the water, whereas TCE does not bioconcentrate to any significant degree.

5.1.1.8 Distribution Coefficient

The distribution coefficient (K_d) is a measure of the equilibrium distribution of a chemical or ion in soil/water systems. The distribution of organic chemicals is a function of both the K_{oc} and the amount of organic carbon in the soil. For ions (e.g., metals), K_d is the ratio of the concentration adsorbed on soil surfaces to the concentration in water. Distribution coefficients for metals vary over several orders of magnitude because the K_d is dependent on the size and charge of the ion and the soil properties governing exchange sites on soil surfaces. Coulomb's Law predicts that the ion with the smallest hydrated radius and the largest charge will be preferentially accumulated over ions with larger radii and smaller charges.

5.1.1.9 Mobility Index

The mobility index (MI) is a quantitative assessment of chemical mobility in the environment based on the water solubility (S), vapor pressure (VP), and the organic carbon partition coeffecient (K_{oc}) of a given material (McCall, et. al., 1983):

$$MI = \log ((S*VP)/K_{oc})$$

The MI for a given chemical is evaluated using the following scale (Ford and Gurba, 1984):

Relative MI	Mobility Description
> 5	extremely mobile
0 to 5	very mobile
-5 to 0	slightly mobile
-10 to –5	immobile
< -10	very immobile

TCE has a MI close to 5 and is considered very mobile. Phthalates and pesticides such as BHC have MIs between -5 anad -10, and are classified as immobile. Lighter molecular weight PAHs, such as naphthalene, have MIs ranging from -5 to 0 and are considered slightly mobile, and the heavier molecular weight PAHs [e.g., benzo(a)pyrene] are classified as very immobile having MIs less than -10 (Table 5-1).

5.1.2 Potential Pathways for Contaminant Migration

Based on the evaluation of existing conditions at Site 46, the following potential contaminant transport pathways may exist at the site:

- Leaching of soil contaminants to groundwater
- Migration of groundwater contaminants
- Volatilization from soil or groundwater

5.1.2.1 Leaching of Soil Contaminants to Groundwater

Contaminants that adhere to soil particles or have accumulated in soil pore spaces can be remobilized and transported to the groundwater as a result of infiltration or precipitation. The rate and extent of this leaching are influenced by:

- The depth of the water table
- Amount of precipitation
- Rate of infiltration
- The physical and chemical properties of the soil
- The physical and chemical properties of the contaminant

The mobility of chemicals at Site 46 will be influenced by the relatively shallow water table, potentially high rates of precipitation, and the sandy soil in the area which may allow a higher rate of infiltration. The contaminants identified at Site 46 (metals and CVOCs) generally have physical and chemical properties that result in low mobility and higher persistence in the environment.

5.1.2.2 Migration of Groundwater Contaminants

Contaminants can migrate in either a dissolved phase or as an immiscible liquid. A contaminant that is present in water above its solubility concentration will form an immiscible liquid. Based on the specific gravity of the contaminant, it will either float or sink in the water. In the case of chlorinated solvents (e.g., chloroform), the contaminant will sink in the water because it has a higher specific gravity than water. Subsurface transport of the immiscible contaminants is governed by a set of factors different from those of dissolved contaminants.

The groundwater data at Site 46 do not provide evidence of immiscible contaminants at concentrations exceeding water solubility levels. Solvents were detected at concentrations less than their water solubilities. Therefore, the migration of groundwater contaminants, for the most part, is likely governed by factors that govern the movement of dissolved contaminants. Three general processes govern the migration of dissolved constituents in groundwater: advection, dispersion, and retardation. Advection is a process by which solutes are carried by groundwater movement. Dispersion is a mixing of contaminated and uncontaminated water during advection. Retardation is a slowing of contaminant migration caused by the reaction of the solute with the aquifer soil.

Contaminant concentrations may be affected by one or more mechanisms during transport. Volatilization or precipitation may physically transform contaminants. Contaminants may be chemically transformed through photolysis, hydrolysis, or oxidation/reduction. Contaminants may also be biologically transformed by biodegradation.

Hydrogeologic data were collected to evaluate movement of groundwater in the shallow surficial aquifer at Site 46. These data were used to estimate the site-specific groundwater flow direction and groundwater flow velocity.

5.1.2.3 Volatilization from Soil or Groundwater

Chemicals in soil can migrate into ambient air either as vapors or by adhering to particulate matter (dusts). Chemicals that have a significant volatility are likely to enter ambient air as vapors. These chemicals are generally considered to be compounds with Henry's Law Constants greater than $1.0x10^{-5}$ and molecular weights less than 200. Chemicals with lower Henry's Law Constants and higher molecular weights are more likely to enter ambient air on particulate matter carried by winds.

Once in groundwater, volatile chemicals may migrate or they may volatilize through the capillary zone and overlying soil layers into ambient air or inside buildings. Chemicals in the vapor phase may migrate horizontally or vertically and can enter buildings through cracks in the foundation or through foundation walls. Once inside buildings, the air concentrations in buildings are subject to various factors, such as building dimensions and ventilation rates. Upon entering ambient air, the vapors are not expected to persist for long periods of time having half-lives in the atmosphere typically measured in hours or a few days. The air concentrations of vapors in ambient air are likely to be quickly diluted by the action of winds. Vapors may also be released directly to ambient air from soil or groundwater during excavation activities.

Many of the contaminants detected in soil and groundwater samples at Site 46 (metals and SVOCs, pesticides and phthalates) are not especially volatile and are not expected to vaporize into the air. Air monitoring was conducted during the soil investigation due to the potential for dust/particulate exposure. Because most of the site is paved with concrete, little dust was generated under normal conditions. However, there is a potential for particulate exposure in areas without grass if the soil is heavily disturbed (e.g., during an excavation).

5.2 CONTAMINANT PERSISTENCE

The life span of the contaminants once released to the environment is controlled by the susceptibility of the contaminant to certain chemical and biological processes that may degrade the contaminants and reduce their remaining mass.

5.2.1 Halogenated VOCs

In general, halogenated aliphatic hydrocarbons are subject to abiotic dehydrohalogenation. This process is an elimination reaction that results in the formation of an ethene from a saturated halogenated compound. Research indicates that microbial degradation of highly chlorinated ethanes is a relatively slow process. Hydrolysis, photolysis, and oxidation are generally not considered to be significant fate processes for the chlorinated ethanes. Limited hydrolysis of saturated aliphatics (i.e., alkanes) may

occur, but it does not appear to be a significant degradation mechanism for unsaturated species (i.e., alkenes).

Under certain conditions, volatilization is a significant fate process for these compounds. Volatilization is only significant at the air-soil or air-water interface. Compounds may volatilize rapidly to the atmosphere from soil or surface water due to low soil adsorption. Adsorption should not be considered as an important fate for these types of compounds when compared to more hydrophobic compounds. BCF factors indicate that these compounds should not bioaccumulate.

5.2.2 PAHs

SVOCs as a class of compounds, and PAHs in particular, are considered to be persistent in the environment. SVOCs in soil are much more likely to bind to soil and be transported via mass transport mechanisms than to go into solution. PAHs are subject to degradation via aerobic bacteria, but may be relatively persistent in the absence of microbial population or macronutrients such as phosphorus and nitrogen. Landspreading applications have indicated that PAHs are highly amenable to microbial degradation in soil. The rate of degradation is influenced by temperature, pH, oxygen concentrations, initial chemical concentrations, and moisture. Photolysis, hydrolysis, and oxidation are not important fate processes for the degradation of PAHs in soil.

5.2.3 Metals

Metals are highly persistent environmental contaminants. They do not biodegrade, photolyze, or hydrolyze. Metals released to the environment generally adsorb to the soil matrix (as compared to being part of the soil structure) and bioaccumulate. Because metals are frequently incorporated into the soil matrix and remain bound to particulate matter, they also migrate from the source areas via bulk movement processes (erosion).

5.3 CONTAMINANT MIGRATION

The mobility of the contaminants, once released to the environment, is controlled by the physical properties of the contaminant, which determine whether the contaminant partitions to more mobile media (air or groundwater) or less mobile media (soil or sediment particles).

5.3.1 Halogenated VOCs

Halogenated aliphatics (e.g., PCE, TCE, and DCE) are generally volatile compounds and are typically considered to be fairly soluble in water with a low capacity for retention by soil organic carbon; therefore, these organic compounds are frequently detected in groundwater. The high volatility and water solubility

of these chemicals dominate their fate the environment. These chemicals may migrate through the soil column after being released by a spill event or by subsurface waste burial as infiltrating precipitation solubilizes them. Some fraction of these chemicals is retained by the soil, but most will continue migrating downward to the water table. Upon reaching the water table migration occurs primarily in the direction of the horizontal hydraulic gradient.

Compounds with specific gravities greater than that of water (e.g., TCE) are often used in various industrial applications such as degreasing. If a large enough spill of these solvents occurs, these chemicals may also migrate as a bulk liquid but will not stop at the water table (i.e., these chemicals will mix with or sink into the aquifer).

5.3.2 SVOCs

SVOCs are generally considered to be fairly immobile chemicals in the environment because they are large molecules with high organic carbon partition coefficients and low solubilities when compared to the volatile organics. However, some of the lighter molecular weight PAHs (a subgroup of SVOCs), such as naphthalene, are more water soluble and environmentally mobile. SVOC compounds in the soil generally do not migrate vertically to a great extent and are more likely to adhere to soil particles and be removed from the site via surface runoff and erosional processes.

PAHs generally have very low solubilities, vapor pressures, and Henry's Law constants and high K_{oc}'s and K_{ow}'s. The low-molecular-weight PAHs (e.g., acenaphthene, anthracene, fluorene, phenanthrene) may volatilize from surface waters, and the high-molecular-weight PAHs [e.g., benzo(a)pyrene, benz(a)anthracene, chrysene, etc.] are less likely to volatilize. PAHs in soil are much more likely to bind to soil and be transported via mass transport mechanisms than to go into solution.

5.3.3 Metals

The mobility of metals is influenced primarily by their physical and chemical properties, in combination with the physical and chemical characteristics of the soil matrix. Factors that assist in predicting the mobility of inorganic species are the soil/pore water pH, soil/pore water oxidation reduction potential of groundwater (Eh), and cation exchange capacity. The mobility of metals generally increases with decreasing soil pH and cation exchange capacity (Table 5-2).

Because inorganics are frequently incorporated into the soil matrix and remain bound to particulate matter, they also migrate from the source areas via bulk movement processes (erosion). The larger, non-colloidal soil particles (greater than 0.45 micron) are not generally considered to be mobile in

groundwater. Metals are also more mobile under acidic conditions. In these cases, it is possible for metals to migrate vertically through the soil column and reach the groundwater.

6.0 HUMAN HEALTH RISK ASSESSMENT

This section presents the human health risk assessment (HHRA) for soil and groundwater at Site 46. The objective of the risk assessment is to determine whether detected concentrations of chemicals in soil and groundwater pose significant threats to potential human receptors under current and/or future land use. The potential risks to receptors are estimated based on the assumption no further actions are taken to control contaminant releases or prevent receptor exposure.

6.1 HUMAN HEALTH RISK ASSESSMENT PROTOCOL

The following USEPA, FDEP, and Navy guidance documents and regulations were used to develop the HHRA methodology and to evaluate potential risks for each site:

- Conducting Human Health Risk Assessments under the Environmental Restoration Program, Department of the Navy, February 2001.
- Navy Policy on the Use of Chemical Background Levels, Department of the Navy, January 2004.
- Technical Report: Development of SCTLs for Chapter 62-777, FAC, Florida Department of Environmental Protection (FDEP), February 2005.
- State of Florida Chapter 62-780 FAC, Contaminated Site Cleanup Criteria, April 2005.
- Risk Assessment Guidance for Superfund: Volume I, Human Health Evaluation Manual (Part A), USEPA, December 1989.
- Human Health Evaluation Manual, Supplemental Guidance: Standard Default Exposure Factors, USEPA, March 1991.
- Guidance for Data Usability in Risk Assessment (Part A), USEPA, April 1992.
- Supplemental Guidance to RAGS: Calculating the Concentration Term, USEPA, May 1992.
- Preliminary Review Draft: Superfund's Standard Default Exposure Factors for the Central Tendency and Reasonable Maximum Exposure, USEPA, May 1993.
- Soil Screening Guidance: Technical Background Document, USEPA, July 1996.

- Exposure Factors Handbook, USEPA, August 1997.

- Supplemental Guidance to RAGS: Region IV Bulletins, Human Health Risk Assessment, USEPA Region 4, May 2000.

- Role of Background in the CERCLA Cleanup Program, USEPA, April 2002.

- Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites, USEPA, December 2002a.

- Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites, USEPA, December 2002b.

- Risk Assessment Guidance for Superfund, Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance, Dermal Risk Assessment), USEPA, July 2004.

The components of a HHRA are addressed in the following sections:

- Data Evaluation Protocol [including data usability assessment; chemical of potential concern (COPC)] selection)
- Exposure Assessment
- Toxicity Assessment
- Risk Characterization
- Uncertainty Analysis

The risk assessment presented in this report considers both USEPA and FDEP policies and guidelines available for conducting HHRAs. Quantitative risk estimates are developed for receptor exposure to surface soil, subsurface soil, and groundwater using the “risk-ratio” approach defined in Section 6.3.3. USEPA Region IV supports the use of this technique. Additionally, comparisons of site soil and groundwater concentrations to FDEP CTLs recommended in FDEP Rule 62-780 are provided (Section 6.6). This rule presents a phased risk-based corrective action process (RBCAP) that is iterative and tailors site rehabilitation tasks to site-specific conditions and risks.

6.1.1 Data Evaluation Protocol

Data evaluation, the first component of a baseline HHRA, is a two-step, medium-specific task involving the compilation and evaluation of analytical data. The first step involves the compilation of the analytical

database and an evaluation of data usability for purposes of HHRA. The second step of the data evaluation is the selection of a medium-specific list of COPCs, which are used to quantitatively or qualitatively determine potential human health risks for site media. COPCs are selected primarily based on a toxicity screen (i.e., a comparison of site contaminant concentrations to conservative toxicity screening values) and a background screen (i.e., a comparison of site concentrations to background concentrations). In addition, as discussed below, factors such as frequency of detection are considered in some cases. The results of the COPC selection process are presented in Section 6.2.

6.1.1.1 Data Usability

Data collected from the field investigation conducted in March 2005 were used to assess risks to potential human and ecological receptors. The data were validated according to USEPA National Validation Functional Guidelines for Organic Data Review (October 1999), the Laboratory and Data Validation Functional Guidelines for Evaluation of Inorganic Analysis (February 1994), and TtNUS SOPs.

Fixed-based analytical results only from the field investigations were used in the quantitative risk evaluation. All detected concentrations with "J" qualifiers are considered positive detections and were used in the risk evaluation. Data with "U" and "UJ" qualifiers and data qualified because of blank contamination were retained and evaluated as nondetects. Field measurements and data regarded as unreliable (i.e., qualified as "R" during the data validation process) were not used in the quantitative risk assessment.

6.1.1.2 Selection of COPCs for Quantitative Risk Assessment

The selection of COPCs is a qualitative screening process used to limit the number of chemicals and exposure routes quantitatively evaluated in the baseline HHRA to those site-related constituents that dominate overall potential risks. Screening, primarily by risk-based concentrations and basewide background levels, is used to focus the risk assessment on meaningful chemicals and exposure routes.

In most cases, a chemical is selected as a COPC and retained for further quantitative risk evaluation if the maximum detection in a sampled medium exceeds the selected risk-based concentration(s) (i.e., the COPC screening level) and the chemical is determined to be present at concentrations exceeding background. This second condition applies only to those chemicals for which background comparison is possible and appropriate (e.g., metals). Background data are not available for organic chemicals. Chemicals eliminated from further evaluation at this time are assumed to present minimal risks to potential human receptors.

6.1.1.2.1 COPC Screening Levels

Several types of screening concentrations were used to identify COPCs for soil and groundwater at Site 46. The screening concentrations are as follows:

Soil

Screening concentrations based on the following criteria were used to select COPCs for surface and subsurface soil:

- USEPA Region 9 Preliminary Remediation Goals (PRGs) for Residential Soil (USEPA Region 9, October 2004)
- Florida SCTLs for Direct Contact (FDEP, April 2005)
- Florida SCTLs for Leachability Based on Groundwater Criteria (FDEP, April 2005)

Groundwater

Screening concentrations based on the following USEPA and State of Florida criteria were used to select COPCs for groundwater:

- USEPA Region 9 PRGs for Tap Water (USEPA Region 9, October 2004). The Region 9 Tap Water PRGs are based on the cumulative effects of ingestion, dermal contact, and inhalation (for volatiles).
- USEPA MCLs (USEPA, Summer 2006)
- Florida GCTLs (FDEP, April 2005). The Florida GCTLs are based on ingestion only. Note that some the GCTLs are calculated risk-based values while others are standards such as primary and secondary MCLs.

Most of the Region 9 PRGs and State of Florida SCTLs are based on a Hazard Quotient (HQ) of 1.0 (i.e., a no adverse non-carcinogenic effect level) or a cancer risk level of $1X10^{-6}$ (i.e., a one-in-one million probability of developing cancer) but are adjusted (lowered) to reflect cumulative risk issues (e.g., Region 9 PRGs are typically adjusted to reflect a HQ of 0.1).

In the risk assessment conducted according to USEPA methodology, the screening levels for both carcinogens and non-carcinogens were developed using the guidance provided in the USEPA Region 4 Human Health Risk Assessment Bulletins -- Supplement to Risk Assessment Guidance for Superfund (RAGS) (USEPA Region 4, May 2000). In this approach, the risk-based USEPA Region 9 screening concentrations correspond to a HQ of 0.1 (for noncarcinogens) or an incremental lifetime cancer risk (ILCR) of 1×10^{-6} (for carcinogens). The Region 9 PRG values for noncarcinogens were multiplied by 0.1 to account for potential cumulative effects of several chemicals affecting the same target area or producing the same adverse non-carcinogenic health effect.

The screening levels used in the risk assessment conducted according to FDEP methodology were developed using the guidance provided in Appendices D and E of the Technical Report for Chapter 62-777 (FDEP, February 2005) and are presented in Section 6.6.

Because of the different exposure scenarios for potential human receptors, COPCs are identified separately for surface and subsurface soil. Surface soil is defined as soil collected from 0 to 0.5 feet bls and subsurface soil is defined as soil collected from depths of 0.5 to 4 feet bls.

Exposure to COPCs in subsurface soil is typically evaluated only for potential exposure during construction or excavation activities. Therefore, a construction/excavation worker is considered to be the receptor most likely exposed to COPCs in subsurface soil. However, subsurface soil could potentially be brought to the surface during future excavation projects resulting in exposure of other receptors such as future residents or workers. For this reason, potential exposure of residents and typical industrial workers to subsurface soils are also evaluated in the risk assessment.

Screening Levels for Lead

Limited criteria are available to evaluate the potential risks associated with lead. There are no strictly risk-based concentrations for this chemical because the USEPA has not derived toxicity values [i.e., cancer slope factors (CSFs), reference doses (RfDs)] for lead. However, recommended screening levels are available for lead in soil and are frequently used to indicate the need for response activities.

Guidance from both the Office of Prevention, Pesticides, and Toxic Substances (OPPTS) and the Office of Solid Waste and Emergency Response (OSWER) recommend 400 mg/kg as the lowest screening level for lead-contaminated soil in a residential setting where children are frequently present (USEPA, 1994). OPPTS identifies 2,000 to 5,000 mg/kg as an appropriate range for areas where contact with soil by children in a residential setting is less frequent. A value of 400 mg/kg is used as the screening level for COPC selection for both surface and subsurface soil.

Guidance for the USEPA Technical Review Workgroup (TRW) for Lead indicates that "a reasonable screening level for soil lead at commercial/industrial (i.e., non-residential) sites is 800 mg/kg" for a typical non-contact intensive worker (USEPA online, 2006). This value is not used for COPC selection but may be used in the qualitative evaluation of lead. The current State of Florida commercial/industrial SCTL for lead in soil is 1,400 mg/kg (FDEP, 2005).

The Florida CTL and Safe Drinking Water Act Action Level of 15 µg/L was used as the screening level for lead in groundwater.

Essential Nutrients and Chemicals without Toxicity Criteria

The essential nutrients calcium, magnesium, potassium, and sodium are not included in the COPC screening process. These inorganic chemicals are naturally abundant in environmental matrices and are only toxic at high doses and, because of the lack of toxicity criteria, risk-based COPC screening levels are not available for these chemicals in the Region 9 PRG table or FDEP CTL tables.

Risk-based screening levels are currently not available for several constituents detected at Site 46 [e.g., acenaphthylene, benzo(g,h,i)perylene, 2-methylnaphthalene, and phenanthrene]. Therefore, screening levels available for surrogate chemicals are used as screening levels for these constituents, as recommended, for example, by USEPA Region 1 (USEPA, August 1999). For example, in the COPC selection for soil at Site 46, the screening level for acenaphthene is used as a surrogate for acenaphthylene, pyrene for benzo(g,h,i)perylene and phenanthrene, and naphthalene for 2-methylnaphthalene.

6.1.1.2.2 Background Screen

Background concentrations are those that would exist in the absence of influence from site operations. The development of soil background datasets for NAS Pensacola is presented in the Site 1 - Sanitary Landfill Remedial Investigation Report (EnSafe/Allen & Hoshall, 1994). The background concentrations for soil were obtained from two reference locations presented in this report and the background concentrations for groundwater were obtained from four reference locations. The background comparisons were conducted according to USEPA Region 4 risk assessment guidance which states, "For naturally occurring inorganics, compare the on-site maximum detected concentration to 2 times the average site-specific background concentration. Eliminate the chemical as a COPC if it is less than 2 times the background level." (USEPA Region 4, 2000). Therefore, if the detected site concentrations of an analyte are less than two times the mean of the background levels, the analyte is not selected as a COPC. The background values used for COPC selection are presented in Tables 6-1 through 6-3. Note that no chemicals were eliminated solely on the basis of background in soil or groundwater at Site 46.

The elimination of chemicals as site-related COPCs on the basis of background comparisons follows Navy Policy on the Use of Background Chemical Levels (DON, 2004). This document also presents the Navy's interpretation of the USEPA guidance provided in the document titled Role of Background in the CERCLA Cleanup Program (USEPA, 2002) and details the methodology to be used in evaluating background under the Navy's Environmental Restoration and Base Realignment and Closure (BRAC) programs. Navy policy applies to both the screening-level and baseline risk assessments and requires the following:

1. A clear and concise understanding of chemicals released from a site thus ensuring the Navy is focusing on remediating the release.

2. The use of background data in the screening-level risk assessment.

    a. The comparison of site chemical levels to risk-based screening criteria.

    b. The comparison of site chemical levels to background concentrations.

    c. The identification of site-related COPCs based on screening criteria comparisons and background comparisons. Site-related COPCs are those chemicals with concentrations exceeding risk-based screening criteria and background concentrations. To the extent possible, site-related COPCs are further evaluated quantitatively in the baseline risk assessment. (Non-site-related COPCs are further discussed in the risk characterization sections of the baseline risk assessments.)

3. The consideration of background in the baseline risk assessment.

    a. The calculation of risk estimates for site-related COPCs only.

    b. The further evaluation of non-site-related COPCs in the risk characterization section only (e.g., the evaluation of chemicals detected at concentrations exceeding screening criteria but less than background concentrations). The Navy considers this comparison to be consistent with USEPA's Role of Background in the CERCLA Cleanup Program (USEPA, 2002).

4. The selection of site cleanup remedial goals at levels not less than background levels. Additionally, cleanup levels should not be developed for chemicals not identified as COCs. As defined in the Navy guidance, COCs are site-related COPCs found to be the risk drivers in the baseline risk assessment and that may pose unacceptable human or ecological risks.

The results of the background screens are presented in Tables 6-1 through 6-3.

Footnotes
1 - Sample and duplicate are considered as two separate samples when determining the minimum and maximum concentrations.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - To determine whether metal concentrations were within background levels, soil concentrations were compared to facility background levels described in Section 6.1.1.1. If the maximum concentration of a chemical is less than the background value, that chemical was not selected as a COPC.
5 - USEPA Region 9 Preliminary Remediation Goal Table. The noncarcinogenic values (denoted with a "N" flag) are the RBC divided by 10 to correspond to a target hazard quotient of 0.1. Carcinogenic values represent an incremental cancer risk of 1.0E-06 (carcinogens denoted with a "C" flag) (USEPA Region 9, November 2004, Update December 29, 2004).
6 - USEPA Soil Screening Levels. EPA Internet Site at http://rais.ornl.gov/calc_start.shtml. (Soil-to-air SSLs for noncarcinogens are divided by 10).
7 - The chemical is selected as a COPC if the maximum detected concentration exceeds the risk-based COPC screening level and is statistically determined to be greater than site background.
8 - The value for naphthalene is used as a surrogate for 2-methylnaphthalene.
9 - The value for acenaphthene is used as a surrogate for acenaphthylene.
10 - The value for pyrene is used as a surrogate for benzo(g,h,i)perylene and phenanthrene.
11 - The PRG for Total PCB congeners (Aroclors) are presented.
12 - The PRG for hexavalent chromium is presented.

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Definitions:
C = Carcinogen
COPC = Chemical Of Potential Concern
J = Estimated value
N = Noncarcinogen

NA = Not Applicable/Not Available
SSL = Soil Screening Level

Rationale Codes:
For selection as a COPC:
ASL = Above Screening Level and site background.

For elimination as a COPC:
BKG = Less than Background Concentration
BSL = Below COPC Screening Level
NUT = Essential nutrient
NTX = No toxicity criteria

Notes:
1 - Sample and duplicate are counted as two separate samples when determining the minimum and maximum detected concentrations and as one sample when determining frequency of detection.
2 - Values presented are sample-specific quantitation limits.
3 - The maximum detected concentration is used for screening purposes.
4 - To determine whether metal concentrations were within background levels, soil concentrations were compared to facility background levels described in Section 6.1.1.1. If the maximum concentration of a chemical is less than the background value, that chemical was not selected as a COPC.
5 - The risk-based COPC screening level for tap water is presented. The value is based upon a target HQ of 0.1 for noncarcinogens (denoted with a "N" flag), or an incremental cancer risk of 1 x 10^{-6} for carcinogens (denoted with a "C" flag) (EPA Region 9, October 2004, Updated December 28, 2004).
6 - USEPA Primary Drinking Water Standard (USEPA, 2006).
7 - The chemical is selected as a COPC if the maximum detected concentration exceeds the COPC screening level and is greater than the concentration detected in the upgradient well.
8 - The PRG for cis-1,2-dichloroethene is used as a surrogate for total 1,2-dichloroethene.
9 - The PRG 2-methylnaphthalene is used as a surrogate for naphthalene.
10 - PRG for chlordane is used as surrogates for alpha- and gamma-chlordane.
11 - The PRG for hexavalent chromium is presented.
12 - No primary MCL available, secondary MCL is presented.

Shaded criterion indicates that the maximum detected concentration exceeds one or more screening criteria. Shaded chemical name indicates that the chemical was retained as a COPC.

Definitions:
NA = Not Applicable
SQL = Sample Quantitation Limit
COPC = Chemical of Potential Concern
J = Estimated Value
C = Carcinogenic
MCL = Maximum Contaminant Level.
NA = Not applicable/not available.
N = Noncarcinogen.
SDWA = Safe Drinking Water Act.
SMCL = Secondary MCL.

Rationale Codes:
For selection as a COPC:
ASL = Above Screening Level

For elimination as a COPC:
BSL = Below Screening Level
NUT = Essential nutrient
BKG = Less than Background Concentration

6.1.1.2.3 Frequency Screen

If an analyte is detected in less than 5 percent of the samples, it may not be selected as a COPC (FDEP, 2005). A frequency screen is conducted only when there are 20 or more samples of the medium of concern. The decision to eliminate a chemical because of low detection frequency is also based on site history (i.e., is there a reason to believe a chemical may or may not be related to historical site activities) and the magnitude of the concentration (i.e., does the concentration of a chemical indicate a potential hotspot area). Note that no chemicals were eliminated as COPCs on the basis of frequency alone.

6.1.1.2.4 Decision Rules for Establishing COPCs

The applicable decision rules for the selection of COPCs are as follows:

- A chemical is selected as a COPC for soil or groundwater if the maximum detected concentration exceeds the screening level and if the background screen indicates the site concentrations are greater than the corresponding background concentrations.

- Individual chemicals may be eliminated as COPCs if they are detected at a frequency of less than 5 percent in any given medium but only if there are no other indications the chemical would pose an unacceptable risk to receptors (e.g., there is no evidence of a contaminant “hot spot”). Chemicals exhibiting unusually high concentrations or are clearly site-related may be retained as COPCs at the discretion of the human health risk assessor.

- If a chemical is not detected in any of the samples in a particular medium, and the detection limits exceeds the risk-based screening levels, the chemical is not selected as a COPC but is qualitatively discussed in the uncertainty analysis section.

- The essential nutrients (calcium, magnesium, potassium, and sodium) are not identified as COPCs.

- Chemicals with concentrations exceeding toxicity screening concentrations but determined to be less than background concentrations based on the background screen are not selected as COPCs. However, as stated previously, no chemicals were eliminated as COPCs on the basis of background alone.

6.2 SELECTION OF COPCS FOR HUMAN HEALTH RISK ASSESSMENT – USEPA METHODOLOGY

The direct contact, USEPA Region 9 risk-based screening levels and USEPA MCLs (for groundwater) defined in Section 6.1.1.2 were used to select COPCs for quantitative evaluation at Site 46. A discussion of the chemicals selected as COPCs (i.e., those chemicals detected at concentrations in excess of USEPA direct contact screening criteria and the rationale for COPC selection are provided in the following paragraphs. COPC selection tables for surface soil, subsurface soil, and groundwater are presented as Tables 6-1, 6-2, and 6-3, respectively.

6.2.1 Surface Soil

Sixteen PAHs, six VOCs phenol, Aroclor-1260, five inorganics, and TPH were detected in surface soil samples collected at Site 46. A comparison of the maximum detected surface soil concentrations to screening levels based on USEPA Region 9 PRGs for residential exposures is presented in Table 6-1. Also presented in Table 6-1 are the results of the site data-to-background data comparisons. The following chemicals were detected in surface soils at maximum concentrations exceeding the direct contact, risk-based COPC screening levels and background, and were retained as COPCs for surface soil:

- TCE
- Aroclor-1260
- Inorganics (aluminum, arsenic, iron, and lead)

These constituents were retained for the quantitative evaluation presented in Section 6.5. The maximum concentrations of aluminum and iron exceeded the Region 9 PRG screening level based on an HQ of 0.1, but were less than the non-adjusted PRG values based on an HQ of 1.0. However, it should be noted that although the detected arsenic concentrations exceeded the risk based COPC screening criteria, the concentrations were within the background range determined by facility-wide statistical analysis of arsenic and iron for NAS Pensacola (Appendix B).

6.2.2 Subsurface Soil

Fourteen PAHs, one phthalate ester, 11 VOCs, Aroclor-1260, and 18 inorganics were detected in subsurface soil samples collected at Site 46. A comparison of the maximum detected subsurface soil concentrations to screening levels based on USEPA Region 9 PRGs for residential exposures is presented in Table 6-2. Also presented in Table 6-2 are the results of the site data-to-background data comparisons. The following chemicals were detected in subsurface soils at maximum concentrations

exceeding the direct contact, risk-based COPC screening levels and background, and were retained as COPCs for subsurface soil:

- TCE
- Inorganics (aluminum and arsenic)

These constituents were retained for the quantitative evaluation presented in Section 6.4. The maximum concentrations of aluminum and iron exceeded the Region 9 PRG screening concentrations but were less than the non-adjusted PRG value. . However it should be noted that although the detected arsenic concentrations exceeded the risk based COPC screening criteria the concenrtrations were within the background range determined by facility-wide statistical analysis of arsenic and iron for NAS Pensacola (Appendix B).

6.2.3 Groundwater

Four PAHs, one phthalate ester, 15 VOCs, pesticides, 20 inorganics, and TPH were detected in groundwater samples collected at Site 46. A comparison of the maximum detected groundwater concentrations to screening levels based on USEPA Region 9 PRGs and USEPA MCLs for residential exposures is presented in Table 6-3. Also presented in Table 6-3 are the results of the site data-to-background data comparisons. The following chemicals were detected in groundwater at maximum concentrations exceeding the direct contact, risk based COPC screening levels and background, and were retained as COPCs for groundwater:

- VOCs (bromodichloromethane, chlorodibromomethane, chloroform, PCE, cis-1,2-DCE, and vinyl chloride)
- PAHs (2-methylnaphthalene and naphthalene)
- Bis(2-ethylhexyl)phthalate
- Inorganics (aluminum, arsenic, barium, cadmium, chromium, iron, lead, manganese, and vanadium)

The trihalomethanes (bromodichloromethane, chlorodibromomethane, and chloroform), PCE, and cis-1,2-DCE were detected at maximum concentrations that exceeded the screening levels based on the Region 9 PRG, but were less than their USEPA MCLs. The maximum concentrations of aluminum, barium, cadmium, iron and manganese exceeded the Region 9 PRG screening levels, but were less than the non-adjusted PRGs. The concentrations of iron and manganese also exceeded the USEPA Secondary MCLs, which are not based on health effects but on aesthetic effects, such as taste and odor. Arsenic, cadmium, chromium exceeded their MCLs and lead exceeded its action level. No chemicals in groundwater were eliminated as COPCs on the basis of background only.

6.3 EXPOSURE ASSESSMENT/ESTIMATION OF RISK

The exposure assessment defines and evaluates, quantitatively or qualitatively, the type and magnitude of human exposure to the chemicals present at or migrating from the site. The exposure assessment is designed to depict the physical setting of the site, to identify potentially exposed populations and applicable exposure pathways, to determine concentrations of COPCs to which receptors might be exposed, and to estimate chemical intakes under the identified exposure scenarios. Actual or potential exposures at a site are determined based on the most likely pathways of contaminant release and transport, as well as human activity patterns. A complete exposure pathway has three components: (1) a source of chemicals that can be released to the environment, (2) a route of contaminant transport through an environmental medium, and (3) an exposure or contact point for a human receptor. These components can be integrated and described by means of a conceptual site model (CSM), which is an essential element of the exposure assessment.

Current or potential human exposures identified by the CSM are evaluated using the "risk-ratio" approach defined in Section 6.3.3. As noted above, this approach is supported by USEPA Region 4. The approach uses exposure point concentrations (EPCs) for the COPCs in soil and groundwater and relevant risk-based concentrations to generate cancer and non-cancer risk estimates for receptors of concern. The risk-based concentrations for soil used to estimate risk are the FDEP SCTLs developed for the residential and industrial land use scenarios and risk-based concentrations developed for other receptors using USEPA and FDEP guidance documents. The risk-based concentrations for groundwater used to estimate risks are the USEPA Region 9 Tap Water PRGs (USEPA Region 9, 2004). The Region 9 PRGs were used for groundwater (instead of the FDEP CTLs) because most of the FDEP GCTLs are not risk-based values. The risk-based concentrations define and incorporate all the exposure factors (e.g., soil and water ingestion rates) used to determine chemical intake/exposure by receptors of concern.

6.3.1 Conceptual Site Model

The foundation of an exposure assessment is the CSM, which identifies site characteristics including potential contaminant sources, contaminant release mechanisms, transport routes, receptors under current and future land use scenarios, and other appropriate information. The CSM integrates information regarding the physical characteristics of the site, exposed populations, sources of contamination, and contaminant mobility (fate and transport) to identify potential exposure routes and receptors to be evaluated in the risk assessment. A well-defined CSM allows for a better understanding of the risks at a site and aids risk managers in the identification of the potential need for remediation. A general overview of CSM information relevant to Site 46 is provided below. Table 6-4 provides a general summary of the potential receptors and exposure routes evaluated in the risk assessment for Site 46.

TABLE 6-4

**EXPOSURE ROUTES FOR QUANTITATIVE EVALUATION
SITE 46 REMEDIAL INVESTIGATION REPORT
NAS PENSACOLA
PENSACOLA, FLORIDA**

Receptors	Exposure Routes
Adult and Adolescent Trespassers / Recreational Users	• Soil dermal contact (surface) • Soil ingestion (surface) • Inhalation of air/dust/emissions (surface soil)
Maintenance Workers	• Soil dermal contact (surface) • Soil ingestion (surface) • Inhalation of air/dust/emissions (surface)
Construction Workers	• Soil dermal contact (surface and subsurface) • Soil ingestion (surface and subsurface) • Inhalation of air/dust/emissions (surface and subsurface)
Occupational Workers	• Soil dermal contact (surface)[1] • Soil ingestion (surface)[1] • Inhalation of air/dust/emissions (surface)[1]
Residents (Adult/Children)	• Soil dermal contact (surface)[1] • Soil ingestion (surface)[1] • Inhalation of air/dust/emissions (surface)[1] • Groundwater ingestion • Groundwater inhalation

Notes:

[1] Occupational workers and residents are also evaluated for exposure to COPCs in subsurface soil. This scenario is included to account for the possibility that subsurface soil could be brought to the surface in future excavation projects.

As note above, the CSM depicts the relationships among the following elements:

- Site sources of contamination
- Contaminant release mechanisms
- Transport/migration pathways
- Exposure routes
- Potential receptors

A general discussion of these elements is provided in Section 1.2.

Site Background and History

The site background and environmental setting is discussed in Section 1.2.

Sources of Environmental Contamination

The primary sources of contamination at Site 46 resulted from routine aircraft maintenance activities and storage of materials used in these activities. The detections of VOCs and metals at Site 46 supports pain stripping activities as a probable source of contamination. The presence of VOCs in groundwater appears to be related to releases at Site 38.

Potential Contaminant Migration Routes

Assuming surface soil, subsurface soil, and groundwater contamination has occurred as a result of chemical usage and chemicals may migrate to deeper subsurface soils and groundwater, the primary plausible contaminant release and migration mechanisms at Site 46 are as follows:

- Migration of soil contaminants downward through the soil column with infiltrating precipitation. Chemicals may continue to migrate in groundwater via dispersion and advection in the downgradient direction.
- Migration of fugitive dusts from surface soils (and subsurface soils if construction/excavation activities occur) into ambient air. Currently, Site 46 is used for vehicle parking rendering this migration route negligible.

A secondary release by stormwater runoff could affect the surface water in the surrounding area resulting in humans and both terrestrial and aquatic biota becoming potential receptors via ingestion and dermal contact. However, because no surface water bodies (other than intermittent streams) are present in the immediate vicinity of Site 46, the potential for runoff from surface soil to a surface water body is not addressed.

Potential Current and Future Receptors of Concern and Exposure Pathways

NAS Pensacola is an active facility and will remain active for the foreseeable future. However, for purposes of completeness, the baseline risk assessment prepared for Site 46 considers receptor exposure under residential, industrial, and recreational land use scenarios. Based on current and potential future land use, the following potential receptors are assumed to be exposed to contaminated environmental media at Site 46:

- Site Maintenance Worker – An on-site receptor under current/future land use. This includes adult military or civilian personnel assigned to work (primarily groundskeeping/outdoor maintenance activities) at a site. This receptor could be exposed to surface soil by incidental ingestion, dermal contact, and inhalation (i.e., airborne particulates/vapors) during groundskeeping or maintenance activities. This receptor would not be expected to be routinely exposed to subsurface soils. This receptor is expected to be exposed to surface soil for 30 days per year based on professional judgment. Maintenance workers are considered one of the more likely receptors under current land use.

- Construction/Excavation Worker – A plausible on-site receptor under future land use if major construction activities were to occur. This receptor could be exposed to surface and subsurface soils by incidental ingestion, dermal contact, and inhalation (i.e., airborne particulates/vapors). The construction worker is assumed to be exposed to soil for 250 days per year (USEPA, 2002b) assuming a Reasonable Maximum Exposure (RME) scenario. Although possible, direct exposure to groundwater by a construction worker is not quantitatively evaluated in the risk assessment. This scenario is considered to be unlikely and risks from exposure to groundwater (via incidental ingestion of small amounts of water) are regarded as negligible relative to direct exposure to soil. In addition, evaluation of exposure of construction workers to groundwater is not specified or recommended in Rule 62-777 FAC.

- Typical Occupational Worker – An on-site receptor under future land use. Future occupational workers may work at the site if the facility were to close and be developed for commercial/industrial uses. To provide information for risk management decisions, potential risks to future occupational workers are quantified in the risk assessments. This receptor could be exposed to surface soil by incidental ingestion, dermal contact, and inhalation (i.e., airborne particulates/vapors). This receptor would not be expected to be routinely exposed to subsurface soils. The occupational worker is expected to be exposed to surface soils for 250 days per year (USEPA, 1993 and 2002) but less intensely than the maintenance or construction worker.

- Adult and Adolescent Recreational User/Trespasser – A plausible receptor under current and future land use. Although access to the base is controlled, once inside the base, access to Site 46 is not limited by any physical constraints. This receptor may be exposed to potentially contaminated surface soil by incidental ingestion, dermal contact, and inhalation (i.e., airborne particulates/vapors). Recreational users/trespassers are assumed to be exposed to COPCs in soil for 45 days per year, based on professional judgment. Direct contact with subsurface soils is not anticipated for this receptor. Recreational users are considered one of the more likely receptors under current land use.

- On-Site Child and Adult Resident – A hypothetical on-site receptor under future land use. The future residential scenario was quantitatively evaluated in the risk assessment for decision-making purposes although this scenario is unlikely for the NAS Pensacola. It is assumed a resident may be exposed to surface soils by incidental ingestion, dermal contract, and inhalation (i.e., airborne particulates/vapors). Future residents could also be exposed to groundwater only if drinking water wells were installed on the site in the future. This is very unlikely since the main source of water for the base is the Navy-owned well field located at NTTC Corry Station north of NAS Pensacola. However, the future residential drinking water scenario was evaluated for decision-making purposes. According to USEPA Region 4 and Region 9 guidance, a resident is assumed to be exposed to groundwater by ingestion and inhalation (i.e., airborne vapors). FDEP in Chapter 62-777 FAC assumes that a receptor is exposed to groundwater by ingestion only. Residential receptors are assumed to be exposed to groundwater 350 days per year (USEPA, 1993) for a total of 30 years.

6.3.2 Calculation of EPCs

The EPC, calculated for COPCs only, is a reasonable estimate of the chemical concentration likely to be contacted over time by a receptor and is used to calculate estimated exposure intakes. Calculation of EPCs considered guidance described in the USEPA's Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites (December 2002a) and Chapter 62-780 FAC (FDEP, 2005).

The 95-percent upper confidence limit (UCL), which is based on the distribution of a dataset, is considered to be the best estimate of the exposure concentration for datasets with 10 or more samples (USEPA, 1992). For datasets with less than 10 samples, the UCL is considered to be a poor estimate of the mean, and the EPC is defined as the maximum concentration. As specified in Chapter 62-780 FAC, the Florida UCL Calculator tool (Version 1.0) was used to calculate the UCLs.

The following decision rules were used to calculate EPCs:

- If a soil dataset contains fewer than 10 samples, the EPC is defined as the maximum detected concentration.
- If a soil dataset contains 10 or more samples, the 95-percent UCL on the arithmetic mean (calculated using the Florida UCL Calculator Tool), which is based on the distribution of the dataset, was selected as the EPC.
- If the calculated 95-percent UCL exceeded the maximum detected concentration, the maximum concentration was used as the EPC.

- Sample and duplicate analytical results were averaged before the EPC was calculated.
- A data value less than the sample-specific detection limit was substituted with one-half the detection limit.

The EPCs for groundwater used in the USEPA risk evaluation are the maximum detected concentrations, except for lead, which is the arithmetic average of the well concentrations.

6.3.3 Chemical Intake and Risk Estimation

To evaluate risks by USEPA methodology, cancer and non-cancer risk estimates for COPCs detected in soil and groundwater are determined using the following simple "risk ratio" technique, which involves the selection (or development) of risk-based concentrations established at the $1x10^{-6}$ cancer risk level or HQ of 1 and the calculation of cancer and non-cancer risks based on the EPC and the risk based concentration:

$$\frac{\text{Risk - based Concentration}}{\text{EPC for COPC}} = \frac{\text{HQ of 1 or Cancer Risk Estimate of 1E - 06}}{\text{HQ or Cancer Risk Estimate for COPC}}$$

This is a valid technique for estimating risk because all of the intake and risk characterization equations used to develop risk-based concentrations are linear. The risk-based concentrations used in the HHRAs for the evaluation of exposure to soil are the State of Florida SCTLs or risk-based concentrations based on the methodology for the development of residential and industrial SCTLs presented in the draft Technical Report: Development of Cleanup Target Levels (CTLs) for Chapter 62-777, FAC (FDEP, 2005). Since most Florida GCTLs are not risk-based values, the risk-based Region 9 PRGs are used in the risk ratio calculations.

Cancer and non-cancer risk estimates for all other receptors evaluated in the HHRA (i.e., the construction worker, the maintenance worker, and the recreational user/trespasser) are based on risk- based concentrations developed using the exposure dose assumptions and the simple intake equations presented in the following sections and the toxicity criteria (slope factors and reference doses) discussed in Section 6.4. The simple intake equations are combined to produce one risk-based concentration per chemical that accounts for ingestion, dermal, and inhalation exposures. (The risk-based concentration calculations are presented in Appendix D.) The risk-based concentrations are established by setting the cancer and non-cancer risk levels at $1x10^{-6}$ or hazard index of 1, respectively, and solving for the associated contaminant concentration in soil as demonstrated in the USEPA Risk Assessment Guidance for Superfund, Part B (USEPA 1991). The exposure assumptions selected for the construction worker, the maintenance worker, the recreational user/trespasser were based on current USEPA risk assessment

guidance (December 1989 and July 2004) and State of Florida guidance (FDEP, 2005). Risk assessment spreadsheets for the calculation of the risk estimates are presented in Appendix E.

6.3.3.1 Incidental Ingestion of Soil

Incidental ingestion of soil by potential receptors coincides with dermal exposure. Exposures associated with incidental ingestion were estimated in the following manner (USEPA, 1989):

$$Intake_{si} = (C_{si})(IR_s)(FI)(EF)(ED)(CF)/(BW)(AT)$$

where:
- $Intake_{si}$ = intake of contaminant "i" from soil (mg/kg/day)
- C_{si} = concentration of contaminant "i" in soil (mg/kg)
- IR_s = ingestion rate (mg/day)
- FI = fraction ingested from contaminated source (dimensionless)
- EF = exposure frequency (days/year)
- ED = exposure duration (year)
- CF = conversion factor ($1x10^{-6}$ kg/mg)
- BW = body weight (kg)
- AT = averaging time (days);
  for noncarcinogens, AT = ED x 365 days/year;
  for carcinogens, AT = 70 years x 365 days/year

As noted above, the State of Florida SCTLs are used calculate cancer and non-cancer risk estimates for the hypothetical future resident and a typical industrial worker exposed to soil. Exposure assumptions for the other receptors are described below and were used to develop risk-based concentrations for the construction worker, the maintenance worker, and the recreational user/trespasser (Appendix E).

A default value of 1.0 (USEPA, 1989) is recommended for the fraction of soil ingested from the contaminated source. The ingestion rates were 330 mg per day (mg/day) for the construction worker (USEPA, 2002b), 50 mg/day for the maintenance workers (FDEP, 2005), and 100 mg/day for adult and adolescent trespassers/recreational users (USEPA, 1993). The exposure frequencies used to estimate intakes for incidental ingestion of soil are presented in Section 6.3.1.

6.3.3.2 Dermal Contact with Soil

Direct physical contact with soil may result in the dermal absorption of chemicals. Exposures associated with the dermal route were estimated in the following manner (USEPA, 1989 and July 2004):

$$Intake_{si} = (C_{si})(SA)(AF)(ABS)(CF)EF)(ED)/(BW)(AT)$$

where:
- $Intake_{si}$ = amount of chemical "i" absorbed during contact with soil (mg/kg/day)
- C_{si} = concentration of chemical "i" in soil (mg/kg)
- SA = skin surface area available for contact (cm^2/day)
- AF = skin adherence factor (mg/cm^2)
- ABS = absorption factor (dimensionless)
- CF = conversion factor ($1x10^{-6}$ kg/mg)
- EF = exposure frequency (days/year)
- ED = exposure duration (year)
- BW = body weight (kg)
- AT = averaging time (days);
  for noncarcinogens, AT = ED x 365 days/year;
  for carcinogens, AT = 70 years x 365 days/year

As noted above, the State of Florida SCTLs were used to calculate cancer and non-cancer risk estimates for the hypothetical future resident and a typical industrial worker. Exposure assumptions for the other receptors are described below and were used to develop risk-based concentrations for the construction worker, the maintenance worker, and the recreational user/trespasser.

The exposed surface areas of the body available for dermal contact are determined on a receptor-specific basis and are based on assumed human activities and clothing worn during exposure events. Current guidance (USEPA, 1997 and 2004) was used to develop the assumptions concerning the amount of skin surface area available for contact for a receptor. The rationales used to select the skin areas are as follows:

- The head, hands, and forearms of excavation/construction worker and maintenance workers were assumed to be exposed to soils (assuming the receptors wear a short-sleeved shirt, long pants, and shoes). As recommended in the Risk Assessment Guidance for Superfund (RAGS) Part E (USEPA, 2004), the skin surface area for a worker was assumed to be 3,300 cm^2. This value represents the average of the 50^{th}-percentile areas of males and females greater than 18 years old.

- For the adolescent trespassers/recreational user, 25 percent of the total body surface area for an adolescent (aged 7 to 16) was assumed to be available for surface soil contact. The RME value (3,280 cm^2) was derived from the 95^{th}-percentile surface area data.

- For the adult trespasser/recreational user assumed to be exposed to surface soil, the exposed skin surface area available for contact was the value recommended for the adult resident in Exhibit 3-5 of RAGS Part E (USEPA, 2004), 5,700 cm^2. This surface area assumes the head, hands, forearms, and lower legs of the receptor are available for contact.

The following values of soil adherence factors and chemical-specific dermal absorption factors provided in RAGS Part E (USEPA, 2004) were used to evaluate risks from exposure to soil:

- Maintenance Worker - 0.2 mg/cm^2 (Exhibit 3.5; USEPA, 2004).

- Construction workers - 0.3 mg/cm^2. This value is the 95^{th}-percentile value for construction workers, (Exhibit 3.3; USEPA, 2004).

- Adolescent Trespassers/Recreational Users - 0.3 mg/cm^2. This adherence factor is the 95^{th}-percentile value presented for soccer players (teens) playing in moist conditions (Exhibit 3.3; USEPA, 2004).

- Future adult trespassers/recreational users - 0.07 mg/cm^2 (Exhibit 3.5; USEPA, 2004).

For the constituents identified as COPCs in soil, the following dermal absorption factors were used (FDEP, 2005):

- TCE – 0.01
- Aroclor-1260 – 0.01
- Aluminum – 0.001
- Arsenic – 0.001
- Iron - 0.001

The same exposure frequencies and durations used in the estimation of ingestion intakes were used to estimate exposure via dermal contact.

6.3.3.3 Inhalation of Air and Fugitive Dust/Volatile Emissions

The amount of a chemical a receptor takes in as a result of breathing is determined using the concentration of the contaminant in air. Intakes of both particulates and vapors/gases are calculated using the same equation, as follows (USEPA, 1991 and 1996):

$$Intake_{ai} = \frac{(C_{ai})(IR_a)(ET)(EF)(ED)}{(BW)(AT)}$$

where: $Intake_{ai}$ = intake of chemical "i" from air via inhalation (mg/kg/day)
C_{ai} = concentration of chemical "i" in air (mg/m^3)
IR_a = inhalation rate (m^3/hour)
ET = exposure time (hours/day)
EF = exposure frequency (days/year)
ED = exposure duration (year)
PEF = Particulate Emission Factor (m^3/kg)
VF = Volatilization Factor (chemical-specific) (m^3/kg)
BW = body weight (kg)
AT = averaging time (days);
= for noncarcinogens, AT = ED x 365 days/year;
= for carcinogens, AT = 70 year x 365 days/year

As noted above, the State of Florida SCTLs are used to calculate cancer and non-cancer risk estimates for the hypothetical future resident and a typical industrial worker. Exposure assumptions for the other receptors are described below and were used to develop risk-based concentrations for the construction worker, the maintenance worker, and the recreational user/trespasser.

The same exposure frequencies and durations used in the estimation of ingestion and dermal intakes of soil were used to estimate exposure via inhalation of air and fugitive dust/volatile emissions. Additionally, for construction/excavation workers and maintenance workers, an inhalation rate of 2.5 m^3 per hour (USEPA, 2002b) and an exposure time of 8 hours/day (i.e., 20 m^3 per day) were used to evaluate risks from inhalation of fugitive dusts and volatile emissions.

For adult and adolescent trespassers/recreational users, inhalation rates of 1.6 m^3 per hour and 1.2 m^3 per hour (USEPA, 1997), respectively, and an exposure time of 4 hours per day were used to evaluate risks from inhalation of fugitive dusts and volatile emissions.

The concentrations of chemicals in air resulting from emissions from soil were developed following procedures presented in USEPA Soil Screening Guidance (USEPA, 1996 and 2002b), as follows:

$$C_a = C_s \times \left[\frac{1}{PEF} + \frac{1}{VF} \right]$$

where: C_a = chemical concentration in air, mg/m^3
C_s = chemical concentration in soil, mg/kg
PEF = Particulate Emission Factor, 1.241 x 10^9 m^3/kg (FDEP, February 2005)
VF = chemical-specific Volatilization Factor, m^3/kg

For chemicals in soil that are not classified as volatile, the above equation reduces to:

$$C_a = C_s \times \left[\frac{1}{PEF}\right]$$

The Particulate Emissions Factor (PEF) relates the concentration of the chemical in soil with the concentration of dust particles in air. The Volatilization Factor (VF) relates the concentration of the chemical in soil with the concentration in ambient air. The VFs used to calculate the alternate SCTLs were obtained from Table 4 of the 62-777 Technical Report (FDEP, 2005). With the exception of the construction worker, the PEF value used to estimate risks from inhalation of fugitive dusts was 1.241 x 10^9 m^3/kg, which was developed by the State of Florida in Chapter 62-777, FAC (FDEP, 2005). The PEF calculated for the construction worker was 2.43 x 10^6 m^3/kg (USEPA, 2002).

6.3.3.4 Ingestion of Groundwater

Residents may be exposed to groundwater via direct ingestion. The Region 9 PRGS used in the risk calculations were derived using the following ingestion intake equation and exposure parameters (USEPA, 1989 and USEPA Region 9, 2004):

$$Intake_{wi} = \frac{(C_{wi})(IR_w)(EF)(ED)}{(BW)(AT)}$$

where: $Intake_{wi}$ = intake of chemical "i" from water (mg/kg/day)
C_{wi} = concentration of chemical "i" in water (mg/L)
IR_w = ingestion rate for groundwater (L/day)
EF = exposure frequency (days/year)
ED = exposure duration (year)
BW = body weight (kg)
AT = averaging time (days);
for noncarcinogens, AT = ED x 365 days/year;
for carcinogens, AT = 70 years x 365 days/year

This scenario assumes that a receptor is exposed 350 days per year for 30 years using an adjusted intake factor (adult + child ingestion rates) of 1.1 L-year/kg-day for carcinogenic effects and an ingestion rate of 2 liters per day for noncarcinogens (USEPA, 2004).

6.3.3.5 Inhalation of Volatiles from Groundwater

Future residents may be exposed to VOC vapors from groundwater while bathing or showering. The Region 9 PRGs used in the risk calculation for VOCs was derived using the following inhalation intake equation and exposure parameters (USEPA, Region 9, 2004):

$$Intake_{winh} = \frac{(C_{wi})(VF_w)(InhF)(EF)(ED)}{(BW)(AT)}$$

where:

$Intake_{winh}$	=	intake of chemical "i" from water by inhalation (mg/kg/day)
C_{wi}	=	concentration of chemical "i" in water (mg/L)
InhF	=	inhalation rate (m^3/day)
VF_w	=	volatilization factor for water (0.5 L/m^3)
EF	=	exposure frequency (days/year)
ED	=	exposure duration (year)
BW	=	body weight (kg)
AT	=	averaging time (days); for noncarcinogens, AT = ED x 365 days/year; for carcinogens, AT = 70 years x 365 days/year

The inhalation scenario assumes that a receptor is exposed 350 days per year for 30 years using an adjusted intake factor (adult + child ingestion rates) of 11 m^3-year/kg-day for carcinogenic effects and an inhalation rate of 20 m^3 per day for noncarcinogens (USEPA Region 9, 2004).

The ingestion and inhalation intake equations are combined to produce one risk-based concentration per chemical that accounts for ingestion and inhalation exposures (USEPA Region 9, 2004).

6.3.3.6 Exposure to Lead

The equations and methodology presented in the previous sections cannot be used to evaluate exposure to lead because of the absence of published dose-response parameters. Exposure to lead was assessed using the following models:

- The latest version of the USEPA's Integrated Exposure Uptake Biokinetic (IEUBK) Model for lead (USEPA, 2002). This model is typically used to evaluate exposure to lead in various media (e.g., soil, water, air) assuming a residential land use scenario.

- The USEPA's TRW Model for Lead (USEPA, 2003). This model is typically used to evaluate exposure to lead in soil only assuming a non-residential land use scenario.

The IEUBK Model for lead (USEPA, 2002) is designed to estimate blood levels of lead in children (under 7 years of age) based on either default or site-specific input values for air, drinking water, diet, dust, and soil exposure. Studies indicate that infants and young children are extremely susceptible to adverse effects from exposure to lead. Considerable behavioral and developmental impairments have been noted in children with elevated blood-lead levels. The threshold for toxic effects from this chemical is believed to be in the range of 10 to 15 µg/dL. Blood-lead levels greater than 10 micrograms per diciliter (µg/dL) are considered to be a "concern."

The IEUBK Model for lead was used to address exposure to lead in children when detected groundwater concentrations exceed the 15 µg/L Federal Action Level promulgated under the SDWA and when detected soil concentrations exceed the OSWER soil screening level of 400 mg/kg for residential land use (USEPA, 1994). Average chemical concentrations, as well as default parameters for some input parameters, were used in the evaluation. Estimated blood-lead levels and probability density histograms are presented as support documentation for this analysis in Appendix E.

Non-residential adult exposure to lead in soil was evaluated using USEPA's TRW Model for lead (USEPA, 2003). In this model, adult exposure to lead in soil is addressed by an evaluation of the relationship between the site soil lead concentration and the blood-lead concentration in the developing fetuses of adult women. The adult lead model generates a spreadsheet for each exposure scenario that is evaluated (i.e., industrial, recreational). The output of the spreadsheet is the probability that the blood-lead concentrations in the fetus exceeds 10 µg/L. The probability that the fetal blood-lead level will exceed 10 µg/L was calculated in accordance with the following USEPA guidelines:

- Use of the TRW Interim Adult Lead Methodology in Risk Assessment (USEPA, 1999).
- Frequently Asked Questions (FAQs) on the Adult Lead Model (USEPA, online, 2006).

No models are currently available to evaluate the periodic exposure of adolescent trespassers/recreational users to lead. Therefore, the results of the IEUBK Model for children are used to qualitatively assess exposure of this receptor because the potential adverse effects from exposure to lead are expected to be of a lesser magnitude for adolescent trespassers than for children.

6.4 TOXICITY ASSESSMENT PROTOCOL

The objective of a toxicity assessment is to identify the potential for human health hazards and adverse effects in exposed populations. A significant portion of the toxicity assessment of the HHRAs has been completed because CSFs and RfDs were selected by the State of Florida during the development of the residential and industrial SCTLs and GCTLs. A CSF is an indicator of the potency of a chemical carcinogen (i.e., the greater the CSF, the more potent the carcinogen). An RfD is the dose at or below which adverse non-carcinogenic effects are not anticipated. These factors represent quantitative estimates of the relationship between the magnitude and types of exposures and the severity or probability of human health effects and were used to develop risk-based concentrations as described above.

6.4.1 Sources of Toxicity Criteria

Oral and inhalation RfDs and CSFs used in the HHRAs were obtained from the following primary recommended USEPA sources:

- Integrated Risk Information System (IRIS) (online)

- USEPA Provisional Peer Reviewed Toxicity Values (PPRTVs) – The Office of Research and Development/National Center for Environmental Assessment (NCEA) Superfund Health Risk Technical Support Center develops PPRTVs on a chemical-specific basis when requested by USEPA's Superfund program.

- Tables 5a and 5b of the FDEP 62-777 Technical Report (FDEP, 2005).

- Other Toxicity Values – These sources include but are not limited to California Environmental Protection Agency (Cal EPA) toxicity values, the Agency for Toxic Substances and Disease Registry (ATSDR) Minimal Risk Levels (MRLs), and the Annual Health Effects Assessment Summary Tables (HEAST) (USEPA, 1997).

Although RfDs and CSFs can be found in several toxicological sources, USEPA's IRIS online database, which is continuously updated, is the preferred source of toxicity values. The USEPA Region 9 PRG Tables (USEPA, 2004) and Region 3 Risk-Based Concentration (RBC) tables (USEPA, 2006) are also used as sources of toxicity criteria when criteria are not available from the aforementioned references.

6.4.2 Toxicity Criteria for Dermal Exposure

RfDs and CSFs found in literature are frequently expressed as administered doses; therefore, these values are considered to be inappropriate for estimating the risks associated with dermal routes of exposure. Oral dose-response parameters based on administered doses must be adjusted to absorbed doses before comparisons to estimated dermal exposure intakes are made.

The adjustment from administered to absorbed dose was made using the following chemical-specific absorption efficiencies published in RAGS Part E:

$$RfD_{dermal} = (RfD_{oral})(ABS_{GI})$$

$$CSF_{dermal} = (CSF_{oral})/(ABS_{GI})$$

where: ABS_{GI} = absorption efficiency in the gastrointestinal tract

6.5 RISK CHARACTERIZATION (USEPA METHODOLOGY)

This section provides a characterization of the human health risks associated with the potential exposures to chemicals in surface soil, subsurface soil, and groundwater at Site 46. The results of the risk characterization are discussed below. Potential risks (non-carcinogenic and carcinogenic) for individual chemicals detected in soil and groundwater at Site 46 were estimated using the simple risk ratio technique presented in Section 6.3.3. As discussed in Section 6.3.1, potential risks were estimated for five receptors (the hypothetical future resident, the typical industrial worker, the construction worker, the maintenance worker, and the recreational user/trespasser) using USEPA and FDEP risk assessment guidance. The total risk from exposure to all COPCs was calculated in accordance with the risk assessment methods outlined in USEPA guidance (USEPA, 1989). Risks to human receptors are also characterized per FDEP guidelines/criteria established in Rule 62-780, FAC in Section 6.6. Supporting documentation for the site-specific HHRAs is presented in Appendix E.

6.5.1 Evaluation of Chemicals Other Than Lead

Quantitative estimates of risk for chemicals other than lead were calculated according to risk assessment methods outlined in Section 6.3.3. The methodology is based on standard USEPA guidance (USEPA, 1989). Lifetime cancer risks are expressed in the form of dimensionless probabilities referred to as ILCRs, which are based on CSFs. An ILCR of $1x10^{-6}$ indicates the exposed receptor has a one-in-one-million chance of developing cancer under the defined exposure scenario. Alternatively, such a risk may be interpreted as representing one additional case of cancer in an exposed population of one million persons. Cancer risk estimates developed for individual chemicals are summed and presented as the

total cancer risk estimate for each receptor. Non-carcinogenic risk estimates for individual chemicals are presented as a HQs, which are based on RfDs. An HQ is the ratio of the intake to the RfD and is an indicator of the potential for adverse non-carcinogenic health effects. An HI is generated by summing the individual HQs for all COPCs. The Hazard Index (HI) is not a mathematical prediction of the severity of toxic effects and therefore is not a true "risk"; it is simply a numerical indicator of the possibility of the occurrence of non-carcinogenic (threshold) effects. As discussed below, HIs were calculated on a target organ/target effect basis.

6.5.2 Evaluation of Lead

Exposure to lead was assessed using USEPA's (IEUBK) Model for lead and the TRW adult lead model (ALM), as described in Section 6.3.3.6. The results of the models are compared to USEPA levels of concern, i.e., predicted lead levels in children and adults should be less than 10 µg/dL and the probability of the blood lead concentrations in a child or fetus exceeding 10 µg/L should be less than 5 percent.

6.5.3 Interpretation of Quantitative Risk Assessment Results

To interpret the quantitative risks and to aid risk managers in determining the need for remediation at a site, quantitative risk estimates are compared to typical risk benchmarks. Calculated ILCRs are interpreted using the USEPA's target range ($1x10^{-6}$ to$1x10^{-4}$) (i.e., a one-in-ten-thousand to one-in-one-million chance of developing cancer) and the State of Florida goal for a total cancer risk of $1x10^{-6}$. HIs are evaluated using a value of 1.0.

The USEPA has defined the range of $1x10^{-6}$ to $1x10^{-4}$ as the ILCR target range for hazardous waste facilities addressed under the CERCLA and the Resource Conservation and Recovery Act (RCRA). Individual or cumulative ILCRs greater than $1x10^{-4}$ are generally not considered as protective of human health. The State of Florida has established a cumulative cancer goal of $1x10^{-6}$ for receptors exposed to contaminated environmental media at a site. These benchmarks are used in the interpretation of the risk characterization results.

An HI exceeding unity (1.0) indicates there may be potential non-carcinogenic health risks associated with exposure. However, when an HI exceeds unity, target organs effects associated with exposure to COPCs are considered. Only the HQs for those chemicals affecting the same target organ(s) or exhibit similar critical effect(s) are regarded as truly additive. Consequently, it may be possible for a cumulative HI to exceed 1.0, but no adverse health effects are anticipated if the COPCs do not affect the same target organ or exhibit the same critical effect (i.e., the HIs developed on a target-organ-specific basis do not exceed 1). Individual target organ HIs for all receptors are presented in the risk calculation tables in Appendix E.

Current USEPA policy regarding lead exposures is to limit the childhood risk of exceeding a 10 µg/dL blood lead level to 5 percent.

6.5.4 Risk Characterization Using USEPA Guidelines

This section contains a summary of the results of the risk characterization for Site 46 conducted according to USEPA guidance. Quantitative risk estimates for potential human receptors were developed for those chemicals identified as COPCs in Section 6.2. Potential cancer risks and HIs were calculated using the methodology presented in Section 6.3 and are summarized in Table 6-5. The results are discussed below. Chemical-specific risks are presented in Appendix E.

Non-Carcinogenic Risk

Cumulative HIs estimated for exposures to surface soil by all receptors were less than 1, except for the hypothetical future resident and the construction worker. For the hypothetical future resident, the non-carcinogenic hazard is driven by TCE; for the construction worker, the non-carcinogenic hazard is driven by aluminum.

Cumulative His estimated for exposures to subsurface soil by all receptors were less than or equal to one, except for the hypothetical future resident. As with surface soil, the non-carcinogenic hazard is driven by TCE.

The cumulative HIs estimated for exposure to groundwater for hypothetical future residents exceeded 1. TCE, 2-methylnaphthalene, naphthalene, chromium, and vanadium all have HQs greater than 1.

Carcinogenic Risk

Cumulative ILCRs for exposure to surface soil, subsurface soil, and groundwater were within USEPA's target risk range of 10^{-4} to 10^{-6} for all receptors except the hypothetical future resident. For the hypothetical future resident's exposure to groundwater, the ILCR exceeded 1×10^{-4}.

However, ILCRs exceeded the State of Florida's target risk level of 1×10^{-6} for exposure to surface and subsurface soil by residents and industrial workers. These exceedances of the Florida target risk level are due to TCE. As stated previously, the risk for residential exposure to groundwater clearly exceeds the State of Florida's target risk level of 1×10^{-6}. The ILCRs for TCE, vinyl chloride, and arsenic exceeded 1×10^{-4}; the ILCRs for chloroform, PCE, and bis(2-ethylhexyl)phthalate exceeded 1×10^{-5}; the ILCRs for bromodichloromethane and chlorodibromomethane exceeded 1×10^{-6}. However, the combined concentrations of the trihalomethanes were less than the MCL.

TABLE 6-5
SUMMARY OF CANCER RISKS AND HAZARD INDICES
SITE 46 REMEDIAL INVESTIGATION REPORT
NAS PENSACOLA
PENSACOLA, FLORIDA

Receptor	Media	Cancer Risk	Chemicals with Cancer Risks $> 10^{-4}$	Chemicals with Cancer Risks $> 10^{-5}$ and $\leq 10^{-4}$	Chemicals with Cancer Risks $> 10^{-6}$ and $\leq 10^{-5}$	Hazard Index	Chemicals with HI > 1
Industrial Workers	Surface Soil	4E-06	- -	- -	Trichloroethene	0.7	- -
	Subsurface Soil	8E-06	- -	- -	Trichloroethene	1	- -
Construction Workers	Surface Soil	4E-07	- -	- -	- -	3	Aluminum
	Subsurface Soil	2E-07	- -	- -	- -	0.2	- -
Maintenance Workers	Surface Soil	7E-07	- -	- -	- -	0.05	- -
Adolescent Recreational Users	Surface Soil	7E-07	- -	- -	- -	0.04	- -
Adult Recreational Users	Surface Soil	4E-07	- -	- -	- -	0.06	- -
Lifelong Recreational Users	Surface Soil	4E-07	- -	- -	- -	NA	- -
Hypothetical Future Residents	Surface Soil	8E-06	- -	- -	Trichloroethene	3	Trichloroethene
	Subsurface Soil	1E-05	- -		Trichloroethene	4	Trichloroethene
	Groundwater	1E-03	Trichloroethene, Vinyl Chloride, Arsenic	Chloroform, Tetrachloroethene,	Bromodichloromethane, Chlorodibromomethane, Bis(2-ethylhexyl)phthalate	60	Trichloroethene, 2-Methylnaphthalene, Naphthalene, Chromium, Vanadium

Notes:
1. No carcinogenic COPCs were detected in the deep groundwater samples.
NA - Not applicable.
HI - Hazard Index.

Exposure to Lead

Lead was identified as a COPC for surface and subsurface soil at Site 46 because maximum detected concentrations (619 mg/kg) exceeded the 400 mg/kg OSWER soil screening level for residential land use. Lead was also identified as a COPC for groundwater because the maximum detected groundwater concentration (23.7 µg/L) exceeded the 15 µg/L USEPA action level at the tap.

As stated previously, published toxicity criteria (CSF, RfD) are not currently available for lead. The USEPA recommends that environmental lead exposures be evaluated using the IEUBK child lead model for residential and the TRW adult lead model for non-residential exposure scenarios. The blood-lead concentration of a receptor is considered a key indicator of the potential for adverse health effects. The IEUBK and TRW models calculate the probability of a receptor's blood-lead level exceeding 10 µg/dL. The USEPA goal is to limit the childhood risk of exceeding a 10 µg/dL blood-lead concentration to 5 percent.

Child Lead Model Results

Current USEPA guidance recommends using the average concentration to evaluate exposure to lead. Therefore, the average lead concentration in surface soil (73 mg/kg) and the average concentration in groundwater (4.34 µg/L), and model default values for other model parameters were used in the IEUBK and TRW model analyses for soil.

The results of the IEUBK model evaluation indicate that the estimated geometric mean blood-lead level for a child resident is 2.3 µg/dL. This blood-lead level is less than the established level of concern (10 µg/dL). Approximately 0.1 percent of children assumed to be exposed to surface soil are expected to experience blood-lead levels greater than 10 µg/dL. This estimate is less than USEPA's goal of limiting exposure to lead so that no more than 5 percent of the exposed children have an estimated blood-lead level greater than the established level of concern (i.e., 10 µg/dL). The results of the IEUBK model are presented in Appendix E.

Adult Lead Model Results

This section presents the results of the ALM evaluation. Full time workers, construction workers, and recreational users were evaluated for exposure to surface soil. The following table summarizes the results of the Adult Lead Model analysis.

ADULT LEAD MODEL RESULTS

Receptor	Predicted Adult Blood Lead Level (µg/dL)	Probability that fetal Blood Lead Level Will Exceed 10 µg/dL	Exceeds USEPA Goal?
Surface Soil (average concentration = 73 mg/kg)[1]			
Full Time Worker	1.5	0.003	No
Construction Worker	1.6	0.004	No
Recreational User	1.4	0.002	No

1. Lead concentrations are averages of samples across the entire site

As shown in the table, the central estimate blood-lead levels for full time occupational workers, construction workers, and recreational users exposed to the average concentration of lead in surface soil (73 mg/kg) were less than the USEPA level of concern of 10 µg/dL and the probabilities that fetal blood-lead levels would be greater than 10 µg lead/dL of blood were less than the USEPA's goal of limiting exposure to lead so that no more than 5 percent of the exposed children have an estimated blood-lead level greater than the established level of concern (i.e., 10 µg/dL).

In summary, the results of the TRW adult lead model evaluations indicate that predicted blood levels for workers and recreational users were acceptable and the probability of workers having children with blood-lead levels greater than 10 µg/dL is less than USEPA's goal of 5 percent. The results of the TRW modeling are presented in Appendix E.

6.6 RISK CHARACTERIZATION USING FDEP RULES 62-777 AND 62-780, FAC

This section describes the State of Florida methodology used to evaluate risks for soil and groundwater at Site 46. The risk assessment methodology is based on guidance provided in Rule 62-780, FAC which makes use of a phased risk-based corrective action process that is iterative and tailors site rehabilitation to site-specific conditions and risks. Rule 62-780 is used in conjunction with Rule 62-777, FAC which provides the methodology used to establish the FDEP CTLs for the residential, commercial/industrial, or alternate land use scenarios. The methodologies described in the following paragraphs are presented in Appendix D and Appendix E of the Technical Report for Chapter 62-777, FAC (FDEP, 2005)

The FDEP risk characterization is performed, in part, through a series of tables in which concentrations of chemicals detected at a site are compared to various FDEP soil and groundwater criteria or to criteria developed according to guidelines presented in Chapter 62-777, FAC. The soil criteria include SCTLs for direct contact (i.e., ingestion, dermal contact, and inhalation), SCTLs for leachability to groundwater, soil saturation concentrations (C_{sat}) for an evaluation of free product, and background levels for metals. The

groundwater criteria include CTLs for direct contact with groundwater (based on ingestion), water solubility values for evaluating the potential for the presence of free product (for organic chemicals), and background levels for metals.

6.6.1 Florida Methodology for Evaluating Soil

Using the guidance provided in Rules 62-780 and 62-777, soil at Site 46 was evaluated for the following land use scenarios:

- Residential land use (Risk Management Option (RMO)Level I)
- Commercial/industrial land use (RMO Level II)
- Recreational land use (RMO Level III)

The evaluation of the hypothetical future residential and commercial/industrial land use of a site is described under RMO Levels I and II, respectively, of Rule 62.780.680. RMO Level III of the rule allows for the development and use of alternative SCTLs based on, for example, a site-specific risk assessment. In this risk assessment, alternative SCTLs were calculated for a recreational user/trespasser using the equations provided in Chapter 62-777 FAC, the most recent toxicological information presented in IRIS, and the exposure factors presented in Section 6.3.3.

A site is first evaluated for residential land use (Level I) for surface and subsurface soil. If the concentrations of chemicals detected at the site are less than their respective criteria, the site is not evaluated further. However, if any of the Level I criteria are exceeded; the site is evaluated for commercial/industrial land use (Level II). The process is then repeated for potential recreational land use (Level III), if necessary. The comparisons conducted for each level are presented in a Tables 6-6 through 6-14 with the chemicals exceeding the relevant screening levels (i.e., the potential COCs) highlighted. Supporting documentation is presented in Appendix E, as necessary. Using the guidance provided in Chapters 62-777 and 62-780 the following evaluations were performed for Site 46:

Comparison with Direct Contact SCTLs. According to the FDEP guidance documents, under RMOs Level I and Level II, the maximum detected concentration of each contaminant may be compared with the respective default SCTL listed in Chapter 62-777, FAC or, the 95 percent UCL of the mean of the site concentrations can be compared with apportioned chronic toxicity-based SCTLs. Under RMO III, UCLs may be compared with apportioned chronic toxicity-based SCTLs only.

In this risk assessment, for RMO Levels I and II, maximum detected surface and subsurface soil concentrations are compared to the default (non-apportioned) SCTLs because an initial review of the

analytical data, the maximum detected concentrations, and the EPCs (calculated as described in Section 6.3.3) indicated the number of potential COCs would not increase if the maximum detected concentration versus the EPC were evaluated using the default SCTLs.) Therefore, if the maximum detected concentration for a chemical exceeds the direct contact SCTL for RMO Levels I and II (and background levels for metals), the constituent is identified as a potential COC and may be further evaluated using various apportionment approaches described in the following sections.

Methods of Apportioning the SCTLs

Simple Apportionment. For situations in which apportionment is applicable, several methods of apportionment are available, as described in Appendix D of the Technical Report. The most straightforward method is simple apportionment. For simple apportionment, the default SCTL for each chemical is divided by the number of chemicals that produce the same type of toxicity. For carcinogens, the value of the simple apportioned SCTL is calculated by dividing the non-apportioned SCTL (residential, commercial/industrial, or recreational) by the number carcinogenic chemicals detected in a surface or subsurface soil dataset. For example, if five carcinogens were detected in a surface soil dataset for a site, the simple apportioned SCTLs for carcinogens are the non-apportioned SCTLs divided by 5 (FDEP, 2005). For noncarcinogens, the simple apportioned SCTL is determined by dividing the non-apportioned SCTL by the number of chemicals impacting the same target organ. If the liver, for example, is identified as the target organ for seven noncarcinogens in a dataset, the simple apportioned SCTLs for those chemicals are the non-apportioned values divided by 7.

Not all SCTLs should be apportioned. The Technical Report (FDEP, February 2005) lists the following exceptions to apportioning:

1. Do not apportion an SCTL based on natural background concentration or practical quantitation limit. These are criteria that are not directly risk-based, and therefore are not subject to apportionment.

2. Do not apportion an SCTL based on acute toxicity. These SCTLs are always regarded as not-to-exceed values, and the default value should be compared with the maximum concentration on site. [Note that acute toxicity SCTLs are applicable only in situations where small children might be present, such as a residence, playground, or school.] Of the chemicals detected in soil at Site 46, the residential SCTLs for barium, copper, and vanadium are acute values.

3. Do not apportion lead (Pb) SCTLs. Both residential and commercial/industrial lead SCTLs are based on a unique type of toxicological analysis that is not amenable to the standard apportionment process.

4. Do not apportion the SCTLs for chemicals present in low concentrations. Eliminate from consideration at a site chemicals whose maximum concentration is less than or equal to 1/10 the default SCTL. Chemicals present in low concentrations are unlikely to contribute substantially to risk and unnecessarily complicate the apportionment process. As shown in Tables 6-6 through 6-12, the maximum concentrations of most detected chemicals (all except carcinogenic PAHs, arsenic, barium, copper, lead, and vanadium) were less than 1/10 of the default SCTLs for surface and subsurface soil. Therefore, the SCTLs for most chemicals detected in soil at Site 46 were not apportioned.

5. Do not apportion the SCTLs for chemicals detected infrequently. A chemical can be eliminated from consideration at a site if it is detected a) in only one out of 10 or more samples, or 5 percent or fewer out of 20 or more samples, and in only one environmental medium; and b) in low concentrations (no more than the default SCTL); and c) there is no reason to believe that the chemical may be present due to historical site activities. These criteria are intended to eliminate chemical detections that are artifacts from sampling, analytical, or other problems. They are not intended to eliminate chemicals present due to site activities in localized areas of contamination.

Weighted Apportionment. In most situations, simple apportionment will be overly conservative in that the sum of the risks represented by the individual chemical SCTLs are likely to be below FDEP target risks of $1x10^{-6}$ and a HI [for each target organ/system or effect] of 1. This can be avoided by weighted apportioning. One method of weighted apportioning involves calculation of ratios of the 95 percent UCLs for chemicals to their SCTLs. The 95 percent UCL for each chemical subject to apportionment is divided by its default SCTL. If the sum of the ratios is less than 1, the chemicals have met the FDEP's risk goals. If the sum is greater than 1, dividing the concentration of each by the sum of the ratios will yield apportioned SCTLs that match exactly the risk goals. In this approach, steps to achieve the apportioned SCTLs are expected to produce proportional decreases in the concentrations of each chemical. This approach makes sense if the chemicals are co-located, such that removal of one chemical results in similar reduction in others.

Non-Proportional Weighted Apportionment. Another method of weighted apportionment is non-proportional reductions in default SCTLs among chemicals with additive effects. As with other methods, the objective of the reduction in default SCTLs is to achieve a situation in which the sum of the risks posed by apportioned SCTLs does not exceed FDEP's risk goals for any health effect. However, in this

Shaded cells indicate that the specified criterion or background level has been exceeded or that the chemical has been selected as a potential COC.

Footnotes:

1 - To determine whether metal concentrations were within background levels, soil concentrations were compared to facility background levels described in Section 6.1.1.1. If the maximum concentration of a chemic is less than the background value, that chemical was not selected as a COPC.

2 - Soil Cleanup Target Levels (SCTLs) for Chapter 62-777, FAC, Florida Department of Environmental Protection (FDEP), April 2005.

3 - A chemical is selected as a potential COC if the maximum concentration exceeds the non-apportioned SCTL and, for metals, if the site concentrations exceed background levels.

NA - Not Applicable. According to Rule 62-780 only naturally occurring (inorganic) constituents are considered in the background evaluation.

J - Estimated concentration less than laboratory method quantitation limit.

Shaded cells indicate that the specified criterion or background level has been exceeded or that the chemical has been selected as a potential COC.

Footnotes:

1 - Exposure point concentrations (EPCs) are maximum concentrations or 95 % upper confidence limits (UCLs) on the arithmetic mean as determined by statistical tests and calculations performed by Florida's UCL Calculator.
2 - To determine whether metal concentrations were within background levels, soil concentrations were compared to facility background levels described in Section 6.1.1.1. If the maximum concentration of a chemical is less than the background value, that chemical was not selected as a COPC.
3 - SCTLs for recreational users were developed using the methods presented in Chapter 62-777, FAC, April 2005 and the most current toxicological data available in IRIS. The recreational users are assumed to be exposed 45 days per year by ingestion, inhalation, and dermal contact. Calculations of the recreational SCTLs are presented in Appendix D.
4 - Target organs are obtained from Table II, Soil Cleanup Target Levels (SCTLs) for Chapter 62-777, FAC, Florida Department of Environmental Protection (FDEP), April 2005.
5 - Values of the simple apportioned SCTLs are determined by dividing the non-apportioned SCTL by the number carcinogenic chemicals or by the number of chemicals impacting the same target organ for noncarcinogens as defined by Chapter 62-777 F.A.C. Chemicals with maximum concentrations less than 0.1 of the non-apportioned SCTL are not included in the apportionment process.
6 - A chemical is selected as a potential COC if the maximum concentration is greater than 3 times the non-apportioned SCTL or if the EPC is greater than the apportioned SCTL, and, for metals, if the site concentrations exceed background levels.
NA - Not Applicable. According to Rule 62-780 only naturally occurring (inorganic) constituents are considered in the background evaluation.
J - Estimated concentration less than laboratory method quantitation limit.

Shaded cells indicate that the specified criterion or background level has been exceeded or that the chemical has been selected as a potential COC.

Footnotes:
1 - Exposure point concentrations (EPCs) are maximum concentrations or 95 % upper confidence limits (UCLs) on the arithmetic mean as determined by statistical tests and calculations performed by Florida's UCL Calculator.
2 - To determine whether metal concentrations were within background levels, soil concentrations were compared to facility background levels described in Section 6.1.1.1. If the maximum concentration of a chemical is less than the background value, that chemical was not selected as a COPC.
3 - SCTLs for recreational users were developed using the methods presented in Chapter 62-777, FAC, April 2005 and the most current toxicological data available in IRIS. The recreational users are assumed to be exposed 45 days per year by ingestion, inhalation, and dermal contact. Calculations of the recreational SCTLs are presented in Appendix D.
4 - Target organs are obtained from Table II, Soil Cleanup Target Levels (SCTLs) for Chapter 62-777, FAC, Florida Department of Environmental Protection (FDEP), April 2005.
5 - Values of the simple apportioned SCTLs are determined by dividing the non-apportioned SCTL by the number carcinogenic chemicals or by the number of chemicals impacting the same target organ for noncarcinogens as defined by Chapter 62-777 F.A.C. Chemicals with maximum concentrations less than 0.1 of the non-apportioned SCTL are not included in the apportionment process.
6 - A chemical is selected as a potential COC if the maximum concentration is greater than 3 times the non-apportioned SCTL or if the EPC is greater than the apportioned SCTL, and, for metals, if the site concentrations exceed background levels.
NA - Not Applicable. According to Rule 62-780 only naturally occurring (inorganic) constituents are considered in the background evaluation.
J - Estimated concentration less than laboratory method quantitation limit.

Shaded cells indicate that the specified criterion or background level has been exceeded or that the chemical has been selected as a potential COC.

1 - To determine whether metal concentrations were within background levels, groundwater concentrations were compared to facility background levels described in Section 6.1.1.1. If the maximum concentration of a chemical is less than the background value, that chemical was not selected as a COPC.
2 - Groundwater Cleanup Target Levels (GCTLs) for Chapter 62-777, FAC, Florida Department of Environmental Protection (FDEP), April 2005.
3 - A chemical is selected as a potential COC if the maximum concentration exceeds the non-apportioned CTL and, for metals, if the site concentrations exceed background levels. According to proposed Florida Rule 62-780 only naturally occurring (inorganic) constituents are considered in the background evaluation.

Definitions:

C = Carcinogen.
COC = Chemical of concern.
J = Estimated value.
NA = Not Applicable
N = Noncarcinogen.
NUT = Essential nutrient
S = Primary or secondary standard

approach, the reduction may be taken unevenly among the chemicals. This approach is useful if the chemicals are not co-located, and removal of one or more chemicals can be achieved more easily or more economically than the others. Risks can be distributed optimally among the apportioned SCTLs based on site conditions, as long as the sums of the risks they represent meet the goals of $1x10^{-6}$ excess cancer risk and a HI of 1.

Weighted apportionment is performed on a chemical by chemical basis when it is feasible and appropriate, as determined by the human health risk assessor. In practice, weighted apportionment is often an option when cumulative quantitative risk assessment results derived as described in preceding sections are less than FDEP risk benchmarks (i.e., a cancer risk estimate of $1x10^{-6}$ for carcinogens and an HI of 1 for noncarcinogens).

When the 95 percent UCL approach is used to develop exposure concentrations, two criteria must be satisfied when comparing site concentrations to the SCTLs, either default or alternative:

1) The 95 percent UCL must meet or be below the apportioned SCTL; and

2) The maximum concentration remaining on site must meet or be below a concentration three-times the unapportioned SCTL in RMO Levels I and II, and below three-times the apportioned SCTL in RMO III. Using the 95 percent UCL as the basis to determine whether the SCTL has been achieved for a site means that some areas can have concentrations above the SCTL, as long as other areas are below. In this context, it is important to insure that concentrations above the SCTL allowed to remain do not constitute an unacceptable health risk.

In the risk assessment for Site 46, SCTLs were apportioned (by simple apportionment) for RMO III. In the Level III evaluations, TCE was the only contaminant with its maximum concentration greater than the nonapportioned SCTL, but its EPC was less than the apportioned SCTL.

Comparison with Leachability-Based SCTLs

The potential for leaching was addressed through comparisons with SCTLs for Leachability Based on Groundwater Criteria (FDEP, 2005). Unlike direct contact SCTLs, which are based primarily on long-term exposure covering a specified area, leachability-based default SCTLs are intended to protect water resources at all locations. Consequently, maximum rather than average (or 95 percent UCL) concentrations are compared with leaching criteria. If the maximum concentration of a chemical exceeds its respective leachability SCTL, that chemical is identified as a potential COC.

Evaluation of Free Product in Soil.

The potential for the presence of free product (for organic chemicals) was evaluated by comparing maximum site concentrations to soil saturation C_{sat} limits. The C_{sat} values are provided in Table 8 of Chapter 62-777 FAC (FDEP, 2005). The C_{sat} comparisons indicated the concentrations of all organic chemicals detected in soil at the sites evaluated in this report were significantly less than the C_{sat} levels. Therefore, it is unlikely these chemicals are present as free product at any of the sites.

6.6.2 Florida Methodology for Evaluating Groundwater

This section describes the methodology used to evaluate groundwater at Site 46 using guidelines presented in Rules 62-780 and 62-777, FAC A detailed discussion of the FDEP approach for evaluating groundwater is presented in Appendix E of the Rule 62-777 Technical Report (FDEP, February 2005).

As with soil, the FDEP risk characterization for groundwater is performed by comparing concentrations of chemicals detected in groundwater with FDEP groundwater criteria (or to criteria developed according to guidelines presented in Chapters 62-777, if necessary). The GCTLs are based on primary and secondary standards (e.g., MCLs) or on human health risk-based criteria, assuming that the groundwater is used as a potable water source (and are based on ingestion only). For contaminants that do not produce cancer, the risk-based CTLs are calculated based on a HI of 1 and incorporate a default relative source contribution factor of 0.2. The relative source contribution factor means, in effect, that no more than 20 percent of the total allowable intake of the contaminant can come from contaminated water. For carcinogens, the default GCTL is based on an excess cancer risk of 1×10^{-6}.

Using the guidance provided in Rules 62-780 and 62-777, groundwater at Site 46 was evaluated for residential land use (RMO Level I). In RMO Level I, the applicable CTL is usually the default value for that contaminant in the groundwater as presented in Table 1 of the Technical Report. If groundwater has the potential to impact surface water, demonstrated by monitoring well data, groundwater flow rate and direction, or fate and transport modeling, the appropriate marine surface water or freshwater surface water CTL also applies to groundwater. However, based on this investigation, groundwater at Site 46 has little potential to impact a surface water body. Therefore, the groundwater evaluation is based on comparison to GCTLs only.

The following evaluations for Site 46 were performed according to Rules 62-777 and 62-780:

- ***Comparison of maximum detected concentrations to GCTLs***. Comparing the GCTLs to maximum detected groundwater concentrations is appropriate for Site 46. If the maximum detected concentration for a chemical exceeds the CTL (and background levels for metals), the constituent is identified as a potential COC for the site.

- ***Evaluation of free product in groundwater***. The potential for the presence of free product (for organic chemicals) was evaluated by comparing maximum site concentrations to water solubility values presented in Table 4, Chapter 62-777, FAC (FDEP, 2005). The water solubility comparisons indicated the concentrations of the few organic chemicals detected in groundwater at Site 46 in 2005 were significantly less than their respective water solubilities. Therefore, it is unlikely these chemicals are present as free product in groundwater at the site.

6.6.3 Risk Characterization Using State of Florida Guidelines

This section contains a summary of the results of the risk characterization for Site 46 conducted using guidelines presented in Florida Rule 62-780 FAC and the Rule 62-777 Technical Report. The results are summarized in Tables 6-6 through 6-14 and are discussed below.

6.6.3.1 Results of Surface Soil Evaluation – Florida Methodology

Level 1 Evaluation (Residential)

Table 6-6 presents a comparison of the maximum detected concentrations for surface soil to the FDEP residential SCTLs. TCE and lead were identified as exceeding the Level 1 SCTLs and were retained as potential COCs for residential exposures to surface soil at Site 46.

Level 2 (Industrial)

The results of the Level 1 evaluation identified two potential COCs; therefore, a Level 2 evaluation was conducted. A comparison of the maximum concentrations in surface soil to the FDEP industrial SCTLs is presented in Table 6-7. TCE was identified as exceeding the Level 2 SCTL, and was retained as a potential COC for industrial exposures to surface soil at Site 46.

Level 3 (Recreational)

The results of the Level 2 evaluation identified one potential COC; therefore, a Level 3 evaluation was conducted assuming a future recreational land use scenario for Site 46. Alternative SCTLs for recreational exposures were derived following the methodology presented in Section 6.3.3. A comparison of the maximum detected concentrations and EPCs for surface soil to the alternative CTLs is

presented in Table 6-8. As shown in the table, the EPCs for all constituents were less than the apportioned alternate SCTLs and the maximum concentration were less than three times the non-apportioned Level 3 alternative SCTLs. Therefore, no constituents were retained as potential COCs for recreational exposure to surface soil at Site 46.

Comparison of Chemicals in Surface Soil with Leachability SCTLs

Table 6-9 presents comparisons of maximum detected concentrations in surface soil with Florida criteria based on leachability to groundwater. As shown in the table, the following constituents had maximum concentrations which exceeded the leachability criteria:

- Acetone
- Chloromethane
- PCE
- TCE
- Phenol
- Aluminum
- Lead

Table 6-9 also presents comparisons of maximum concentrations with soil saturation concentrations to evaluate the potential for presence of free product. As shown in the table, the concentrations of organic compounds in surface soil were significantly less than the C_{sat} concentrations, indicating that free product is not present in surface soil.

6.6.3.2 Results of Subsurface Soil Evaluation – Florida Methodology

Level 1 Evaluation (Residential)

Table 6-10 presents a comparison of the maximum detected concentrations for subsurface soil to the FDEP residential SCTLs. TCE and arsenic were identified as exceeding the Level 1 SCTLs and were retained as potential COCs for residential exposures to subsurface soil at Site 46.

Level 2 (Industrial)

The results of the Level 1 evaluation identified two potential COCs; therefore, a Level 2 evaluation was conducted. A comparison of the maximum concentrations for subsurface soil to the FDEP industrial

SCTLs is presented in Table 6-11. TCE was identified as exceeding the Level 2 SCTL, and was retained as a potential COC for industrial exposures to subsurface soil at Site 46.

Level 3 (Recreational)

The results of the Level 2 evaluation identified one potential COC; therefore, a Level 3 evaluation was conducted assuming a future recreational land use scenario. Alternative SCTLs for recreational exposures were derived following the methodology presented in Section 6.3.3. A comparison of the maximum detected concentrations and EPCs for subsurface soil to the alternative CTLs is presented in Table 6-12. No constituents were identified as exceeding the Level 3 SCTLs.

Comparison of Chemicals in Subsurface Soil with Leachability SCTLs

Table 6-13 presents comparisons of maximum detected concentrations in subsurface soil with Florida criteria based on leachability to groundwater. Maximum concentrations of the following exceeded the leachability criteria:

- Chloromethane
- Cis-1,2-DCE
- Chloroform
- Methylene Chloride
- PCE
- TCE
- Lead

Table 6-13 also presents comparisons of maximum concentrations with soil saturation concentrations to evaluate the potential for presence of free product. As shown in the table, the concentrations of organic compounds in subsurface soil were significantly less than the C_{sat} concentrations, indicating that free product is not present in subsurface soil.

6.6.3.3 Results of Groundwater Evaluation – Florida Methodology

Level 1 Evaluation (Residential)

Groundwater was evaluated on for future residential use (Level 1). Table 6-14 presents a comparison of the maximum detected concentrations in groundwater to the FDEP GCTLs. The following chemicals were identified as exceeding the Level 1 CTLs and were retained as potential COCs for residential exposures to groundwater at Site 46:

- Bromodichloromethane
- Chlorodibromomethane
- TCE
- Vinyl Chloride
- Bis(2-ethylhexyl)phthalate
- Naphthalene
- Inorganics (aluminum, arsenic, barium, cadmium, chromium, iron, lead, manganese, sodium, and vanadium)

The maximum detected concentrations of bis(2-ethylhexyl)phthalate, naphthalene, aluminum, arsenic, iron, and vanadium exceeded three times the GCTLs. Note that GCTLs for aluminum (200 µg/L), iron (300 µg/L), and manganese (50 µg/L) are secondary standards which are not based on health effects but on aesthetic effects, such as taste and odor. Also, bis(2-ethylhexyl)phthalate was only detected in one sample.

6.7 HUMAN HEALTH RISK UNCERTAINTY ANALYSIS

This section presents a summary of uncertainties inherent in the risk assessment and includes a discussion of how they may affect the quantitative risk estimates and conclusions of the risk analysis. The baseline HHRA for Site 46 was performed in accordance with current USEPA and Florida guidance. However, there are varying degrees of uncertainty associated with the baseline HHRA. The following sections discuss general uncertainties in risk assessment and uncertainties specific to the risk assessment for Site 46.

Uncertainty in the selection of COPCs was related to the current status of the predictive databases, the grouping of samples, the numbers, types and distributions of samples, data quality, and the procedures used to include or exclude constituents as COPCs. Uncertainty associated with the exposure assessment included the values used as input variables for a given intake route or scenario, the assumptions made to determine EPCs, and the predictions regarding future land use and population characteristics. Uncertainty in the toxicity assessment included the quality of the existing toxicity data needed to support dose-response relationships and the weight-of-evidence used to determine the carcinogenicity of COPCs. Uncertainty in risk characterization was associated with exposure to multiple chemicals and the cumulative uncertainty from combining conservative assumptions made in earlier steps of the risk assessment process.

Whereas there were various sources of random uncertainty and bias, the magnitude of bias and uncertainty and the direction of bias was influenced by the assumptions made throughout the risk

assessment including selection of COPCs and selection of values for dose-response relationships. Throughout the entire risk assessment assumptions that considered safety factors were made so that the final calculated risks were overestimated.

Generally, risk assessments carry two types of uncertainty: measurement and informational uncertainty. Measurement uncertainty refers to the usual variance that accompanies scientific measurements. For example, this type of uncertainty is associated with analytical data collected for each site. The risk assessment reflects the accumulated variances of the individual values used.

Informational uncertainty stems from inadequate availability of information needed to complete the toxicity and exposure assessments. Often, this gap is significant, such as the absence of information on the effects of human exposure to low doses of a chemical, the biological mechanism of action of a chemical, or the behavior of a chemical in soil.

Once the risk assessment is complete, the results must be reviewed and evaluated to identify the type and magnitude of uncertainty involved. Reliance on results from a risk assessment without consideration of uncertainties, limitations, and assumptions inherent in the process can be misleading. For example, to account for uncertainties in the development of exposure assumptions, conservative estimates were made to ensure that the particular assumptions were protective of sensitive subpopulations or the maximum exposed individuals. If a number of conservative assumptions are combined in an exposure model, the resulting calculations can propagate the uncertainties associated with those assumptions, thereby producing a much larger uncertainty for the final results. This uncertainty is biased toward overpredicting both carcinogenic and non-carcinogenic risks. Thus, both the results of the risk assessment and the uncertainties associated with those results must be considered when making risk management decisions.

This interpretation of uncertainty is especially relevant when the risks exceed the point of departure for defining "acceptable" risk. For example, when risks calculated using a high degree of uncertainty are less than an acceptable risk level (i.e., 10^{-6}), the interpretation of no significant risk is typically straightforward. However, when risks calculated using a high degree of uncertainty exceed an acceptable risk level (i.e., 10^{-4}); a conclusion can be difficult unless uncertainty is considered.

6.7.1 Uncertainty in Selection of COPCs

The most significant issues related to uncertainty in COPC selection were the usability of existing databases (i.e., the use of validated and unvalidated sample results [only validated data were used in this risk assessment] and the completeness, precision, and accuracy of the data set), the inclusion of chemicals potentially attributable to background in the quantitative risk assessment, the screening levels

used, and the absence of screening levels for a few chemicals detected in the site media. A brief discussion of each of these issues is provided in the remainder of this section.

Chemicals Potentially Attributable to Background

No chemicals in soil or groundwater were eliminated from the risk assessment on the basis of background only. Therefore, it is possible that risks are overestimated by the inclusion of some metals as COPCs. Note that the NAS Pensacola reference concentrations used for the background evaluation for soil are based on data from only two locations and for groundwater are based on four locations. Therefore, the reference concentrations for NAS Pensacola may not be adequately represent background conditions. For example, arsenic was selected as a COPC for surface and subsurface soil because the maximum detected concentrations in these media exceeded the arsenic screening level and the reference concentration (1.56 mg/kg). USEPA Region 9 indicates that background levels of arsenic in the United States range from 0.1 to 97 mg/kg and ATSDR indicates a background range of 1 to 40 mg/kg. The maximum detected concentration of arsenic in soil at NAS Pensacola are at the low end of these concentration ranges and it is possible that levels of arsenic at Site 46 are naturally occurring. In addition, a facility-wide stistical analyis was completed comparing arsenic and iron to determine true representative background concentrations. Based on the statistical analysis, all detected arsenic concentrations in Site 46 soils were within the background range (0.1 to 17.5 mg/kg) determined by statistical analysis (Appendix B).

COPC Screening Levels

The use of risk-based screening values (for the USEPA analysis) based on conservative land use scenarios (i.e., residential land use for soil and groundwater) corresponding to an ILCR of 10^{-6} and HI of 0.1 ensured that all the significant contributors to risk from a site were evaluated. The elimination of chemicals present at concentrations that correspond to an ILCR less than 10^{-6} and an HI less than 0.1 should not affect the final conclusions of the risk assessment because those chemicals are not expected to cause a potential health concern at the detected concentrations.

Chemicals without Established Screening Levels

Region 9 PRGs are currently not available for some constituents (e.g., 1-methylnaphthalene, 2-methylnaphthalene, acenaphthylene, benzo(g,h,i)perylene, and phenanthrene). Appropriate surrogates were selected for these chemicals based on similar chemical structures, if available. For example, naphthalene was used as a surrogate for 1-methylnaphthalene and 2-methylnaphthalene, and, pyrene was used as a surrogate for benzo(g,h,i)perylene and phenanthrene. Applying toxicity values of one compound to another increases the uncertainty in the risk assessment both in regard to the selection of

COPCs and the calculated risks. The direction of the uncertainty is not known. Note that the State of Florida does provide CTLs for these compounds and they were evaluated in the analysis using FDEP methodology. Therefore, the uncertainty associated with the use of surrogates is likely to be minimal.

6.7.2 Uncertainty in the Exposure Assessment

Uncertainty in the exposure assessment arose because of the methods used to calculate EPCs, the determination of land use conditions, the selection of receptors and scenarios, the estimation of EPCs, and the selection of exposure parameters. Each of these is discussed below.

Land Use

The current land use patterns at NAS Pensacola are well established, thereby limiting the uncertainty associated with land use assumptions. Land use at Site 46 is currently limited and is expected to be limited in the future, as long as NAS Pensacola remains open. To be conservative, risks to potential and future construction workers, maintenance workers, occupational workers, recreational users, and on-site residents were estimated for the site. Maintenance workers and recreational users are considered to be the most likely receptors under current land use.

Exposure Point Concentrations

EPCs for soil were calculated using the Florida UCL Calculator (Version 1.0). Uncertainty is associated with the use of the 95 percent UCL on the mean concentration as the EPC. As a result of using the 95 percent UCL, the estimations of potential risk for the RME scenario were most likely overstated because this is the upper limit on the mean concentration that potential receptors would be exposed to over the entire exposure period. In some cases, the maximum concentration was used as the EPC. Use of the maximum concentration as the EPC tends to overestimate potential risks because receptors are assumed to be exposed continuously to the maximum concentration for the entire exposure period. Uncertainty was also introduced when the nondetects results were assigned a value of one-half the nondetect quantitation limit in the calculation of the EPC. This may either overstate or understate the risks to potential receptors.

As discussed in Section 6.3.2, the calculated risks for groundwater in the risk evaluation were based on the assumption that EPCs for groundwater were the maximum detected concentrations. Using the maximum detected concentrations may result in overestimation of risks.

There was also uncertainty in assuming that current groundwater concentrations will not change in the future and this introduces additional uncertainty in the EPCs and risks for groundwater COPCs.

Concentrations in groundwater may diminish over time due to natural attenuation processes involving source depletion and dilution.

Exposure Routes and Receptor Identification

The determination of various receptor groups and exposure routes of potential concern was based on current land use observed at the site and the anticipated future land use. Therefore, the uncertainty associated with the selection of exposure routes and potential receptors was minimal because they were considered to be well defined. Although residential use of groundwater was evaluated as an exposure scenario, groundwater is not currently used at the site nor is it expected to be used in the future. Three water wells located on NAS Pensacola provide emergency backup potable water supply. The backup water supply wells obtain groundwater from the sand and gravel aquifer at depths ranging from 224 to 250 feet below land surface. The nearest potable water well to Site 46 is located approximately 5,000 feet to the northwest of the site. The evaluation of direct exposure to groundwater in the HHRA was included primarily to aid in risk management decision making.

Exposure Parameters

The risk-based concentrations used to estimate risks by the USEPA methodology were calculated by the equations and exposure factors presented in Section 6.3.3. Each exposure factor selected for use in the risk assessment has some associated uncertainty. Generally, exposure factors were based on surveys of physiological and lifestyle profiles across the United States. The attributes and activities studied in these surveys generally have a broad distribution. The exposure factors used in this report, in most cases, were obtained from USEPA or Florida guidance documents for the RME, which generally specify the use of the 95th percentile value for most parameters. Therefore, the selected values for the RME receptor represented an upper bound of the observed or expected habits of the majority of the population.

Generally, the uncertainty can be assessed quantitatively for many assumptions made in determining factors for calculating exposures and intakes. Many of these parameters were determined from statistical analyses on human population characteristics. Often, the database used to summarize a particular exposure parameter (i.e., body weight) is quite large. Consequently, the values chosen for such variables in the RME scenario have low uncertainty.

For many parameters for which limited information exists (i.e., dermal absorption of chemicals from soil), greater uncertainty exists. For example, current USEPA dermal guidance (USEPA, 2004) does not provide dermal absorption factors for exposure to most metals (except arsenic and cadmium) in soil.

Therefore, risks for dermal contact from soil were not evaluated for most metals in this risk assessment. Consequently, risks from exposure to soil may have been underestimated.

6.7.3 Uncertainty in the Toxicological Evaluation

The RBCs used to assess risk were also developed using the toxicity criteria discussed in Section 6.4. Uncertainties associated with the toxicity assessment (determination of RfDs and CSFs and use of available criteria) are presented in this section.

Derivation of Toxicity Criteria

Uncertainty associated with the toxicity assessment was associated with hazard assessment and dose-response evaluations for the COPCs. The hazard assessment dealt with characterizing the nature and strength of the evidence of causation or the likelihood that a chemical that induces adverse effects in animals will also induce adverse effects in humans. Hazard assessment of carcinogenicity was evaluated as a weight-of-evidence determination using USEPA methods. Positive animal cancer test data suggest that humans contain tissue(s) that may manifest a carcinogenic response; however, the animal data cannot necessarily be used to predict the target tissue in humans. In the hazard assessment of non-cancer effects, however, positive animal data often suggest the nature of the effects (i.e., the target tissues and type of effects) anticipated in humans.

Uncertainty in hazard assessment arose from the nature and quality of the animal and human data. Uncertainty was reduced when similar effects were observed across species, strain, sex, and exposure route; when the magnitude of the response was clearly dose related; when pharmacokinetic data indicated a similar fate in humans and animals; when postulated mechanisms of toxicity were similar for humans and animals; and when the COC was structurally similar to other chemicals for which the toxicity is more completely characterized.

Uncertainty in the dose-response evaluation included the determination of a CSF for the carcinogenic assessment and derivation of an RfD for the non-carcinogenic assessment. Uncertainty was introduced from interspecies (animal to human) extrapolation, which, in the absence of quantitative pharmacokinetic or mechanistic data, is usually based on consideration of interspecies differences in basal metabolic rate. Uncertainty also resulted from intraspecies variation. Most toxicity experiments are performed with animals that are very similar in age and genotype, so intragroup biological variation is minimal, but the human population of concern may reflect a great deal of heterogeneity, including unusual sensitivity or tolerance to the COPC. Even toxicity data from human occupational exposure reflect a bias because only those individuals sufficiently healthy to attend work regularly (the "healthy worker effect") and those not unusually sensitive to the chemical are likely to be occupationally exposed. Finally, uncertainty arises

from the quality of the key study from which the quantitative estimate was derived and the database used. For cancer effects, the uncertainty associated with dose-response factors was mitigated by assuming the 95 percent upper bound for the slope factor. Another source of uncertainty in carcinogenic assessment is the method by which data from high doses in animal studies are extrapolated to the dose range expected for environmentally exposed humans. The linearized multistage model, which is used in nearly all quantitative estimations of human risk from animal data, is based on a nonthreshold assumption of carcinogenesis. Evidence suggests, however, that epigenetic carcinogens, as well as many genotoxic carcinogens, have a threshold below which they are noncarcinogenic. Therefore, the use of the linearized multistage model was conservative for chemicals that exhibited a threshold for carcinogenicity.

For non-cancer effects, additional uncertainty factors may have been applied in the derivation of the RfD to mitigate poor quality of the key study or gaps in the database. Additional uncertainty for non-cancer effects arose from the use of an effect level in the estimation of an RfD, because this estimation was predicated on the assumption of a threshold less than which adverse effects were not expected. Therefore, an uncertainty factor is usually applied to estimate a no-effect level. Additional uncertainty arose in estimation of an RfD for chronic exposure from subchronic data. Unless empirical data indicated that effects did not worsen with increasing duration of exposure, an additional uncertainty factor was applied to the no-effect level in the subchronic study. Uncertainty in the derivation of RfDs was mitigated by the use of uncertainty and modifying factors that normally ranged between 3 and 10. The resulting combination of uncertainty and modifying factors may have reached 1,000 or more.

The derivation of dermal RfDs and CSFs from oral values may have caused uncertainty. This was particularly the case when no gastrointestinal absorption rates were available in the literature or when only qualitative statements regarding absorption were available.

Uncertainty Associated with Evaluation of the Dermal Exposure Pathway

According to RAGS Part E (USEPA, 2004), risks for dermal absorption of chemicals in soil are quantitatively evaluated for arsenic, cadmium, chlordane, 2,4-dichlorophenoxyacetic acid, DDT, TCDD (and other dioxins), PAHs, PCBs, pentachlorophenol, and SVOCs only because of the limited information guidance available to evaluate dermal exposure to other constituents. However, risks associated with dermal exposure to other metals in soil (except for arsenic and cadmium) were also evaluated in the risk assessment using the dermal absorption factors provided in FDEP guidance (FDEP, 2005). Generally, potential risks associated with these metals may result in an overestimation of risk because metals do not readily desorb from soil and become available for absorption through the skin.

The Region 9 PRGs used to assess risks for groundwater are based on ingestion and inhalation (for volatiles) but dermal effects are not considered in the PRG calculations. For some chemicals (e.g., PCBs and PAHs) the omission of the aqueous dermal pathway can be significant. However, for the types of chemicals detected in groundwater at Site 46 (i.e., VOCs and metals), the aqueous dermal pathway is generally not important. Therefore, the effects of omitting dermal contact from the PRG calculations is expected to be negligible.

Use of Iron Toxicity Criteria

An NCEA provisional RfD was used to evaluate non-carcinogenic effects from exposure to iron. The provisional RfD for iron is based on allowable intakes rather than adverse effect levels. Therefore, there was some degree of uncertainty associated with the use of the RfD used to calculate risk-based concentrations for iron. Note that some USEPA regions (e.g., Region 1) consider the use of the oral RfD for iron inappropriate and recommend that this metal not be evaluated quantitatively in risk assessments.

Alternate RfD for Manganese

The oral RfD for manganese listed in the Region 9 PRG table (0.024 mg/kg/day) was used to calculate the PRG for evaluating risks for residential exposure to groundwater. This value includes a modification factor of 3 and an adjustment factor for the dietary contribution which is applied to the non-dietary reference dose (0.14 mg/kg/day) presented in IRIS. IRIS indicates that an adjustment for the dietary contribution should be subtracted from this allowable intake. Using the modified and adjusted RfD results in risk estimates 6 times higher than if the non-dietary reference dose were used.

6.7.4 Uncertainty in the Risk Characterization

Uncertainty in risk characterization resulted from assumptions made regarding additivity of effects from exposure to multiple COPCs from various exposure routes. High uncertainty existed when summing non-cancer risks for several substances across different exposure pathways. This assumed that each substance has a similar effect and/or mode of action. Even when compounds affect the same target organs, they may have different mechanisms of action or differ in their fate in the body, so additivity may not have been an appropriate assumption. However, the assumption of additivity was considered because in most cases it represented a conservative estimate of risk.

Risks to any individual may also have been overestimated by summing multiple assumed exposure pathway risks for any single receptor. Although every effort was made to develop reasonable scenarios, not all individual receptors may have been exposed via all pathways considered.

Finally, the risk characterization did not consider antagonistic or synergistic effects. Little or no information was available to determine the potential for antagonism or synergism for the COPCs. Because chemical-specific interactions could not be predicted, the likelihood for risks to be overpredicted or underpredicted could not be defined, but the methodology used was based on current USEPA guidance.

6.8 SUMMARY AND CONCLUSIONS

An HHRA was conducted for the chemical concentrations detected in surface soil, subsurface soil, and groundwater samples collected at Site 46. The evaluation was conducted using both USEPA and State of Florida regulations and guidelines for HHRA. The results of the USEPA and Florida risk assessments are summarized in the following sections.

6.8.1 Summary of USEPA Risk Assessment

The USEPA risk assessment considered five receptors, the hypothetical future resident, the typical industrial worker, the construction worker, the maintenance worker, and the trespasser/recreational user, assuming exposure via the ingestion, dermal contact, and inhalation route of exposures. However, maintenance workers and trespassers/recreational users are considered to be the most likely receptors at Site 46 under current land use.

The list of COPCs for Site 46 included the following:

- Surface Soil – TCE, Aroclor 1260, aluminum, arsenic, iron, and lead
- Subsurface Soil – TCE, aluminum, arsenic, and iron
- Groundwater – bromodichloromethane, chlorodibromomethane, chloroform, PCE, cis-12,-DCE, vinyl chloride, 2-methylnaphthalene, naphthalene, bis(2-ethylhexyl)phthalate, aluminum, arsenic, barium, cadmium, chromium, iron, lead, manganese, and vanadium

Quantitative estimates of non-carcinogenic and carcinogenic risks (HIs and ILCRs, respectively) were developed for potential human receptors. Exposure to lead was evaluated by the USEPA's Child Lead Model (IEUBK) and ALM. Results of these evaluations are summarized below.

Clearly, the carcinogenic and non-carcinogenic risks for the hypothetical future resident exceed USEPA and FDEP target risk levels and HIs, respectively, for soil and groundwater. In soil, the primary driver of risk is TCE; in groundwater, the primary drivers of risk are chlorinated VOCs and arsenic.

For the construction worker, concentrations of aluminum in surface soil elevate the HI above the target of one. For the industrial worker, concentrations of TCE in surface and subsurface soil elevate the ILCR above 1×10^{-6}.

Concentrations of lead in soil and groundwater do not result in blood level lead concentrations in any of the evaluated receptors.

6.8.2 Summary of Florida Risk Assessment

The risk assessment conducted per the State of Florida regulations and guidelines evaluated risks to a hypothetical future resident and a typical industrial worker using the published SCTLs for the residential and industrial land use scenario, respectively. Risks to a hypothetical future recreational user were evaluated using SCTLs specifically developed for this risk assessment as stipulated in the State of Florida regulations and guidelines. The following chemicals were identified as potential COCs for surface soils based on a comparison of maximum concentrations or EPCs to these SCTLs:

FLORIDA SURFACE SOIL EVALUTION

Residential SCTLs	Industrial SCTLs	Recreational SCTLs
TCE	TCE	
Lead		

The following chemicals were identified as potential COCs for subsurface soils based on a comparison of maximum concentrations or EPCs to the SCTLs:

FLORIDA SUBSURFACE SOIL EVALUTION

Residential SCTLs	Industrial SCTLs	Recreational SCTLs
TCE	TCE	
Arsenic		

The following chemicals were identified as potential COCs for groundwater based on a comparison of maximum concentrations to GCTLs:

FLORIDA GROUNDWATER EVALUATION

GCTLs
Bromodichloromethane
Chlorodibromomethane
TCE
Vinyl chloride
Bis(2-ethylhexyl)phthalate
Naphthalene
Aluminum
Arsenic
Barium
Cadmium
Chromium
Iron
Lead
Manganese
Sodium
Vanadium

Note that aluminum, iron, and manganese were identified as potential COCs for groundwater because the maximum concentrations exceeded CTLs which are, in effect, USEPA Secondary MCLs. Secondary MCLs are criteria based not on health effects but rather on aesthetic effects such as taste and odor. Also, note that HQs for aluminum, iron, and manganese calculated in the USEPA evaluation were less than the USEPA and Florida goal of unity for non-carcinogenic health effects.

Chemicals detected in soil were also evaluated for the potential to impact groundwater quality at the site by comparing maximum concentrations with FDEP soil screening levels (SSLs) for migration from soil to groundwater. This evaluation indicated that that the concentrations of constituents detected in soil, specifically the chlorinated VOCs, were likely to potentially contribute to groundwater contamination.

7.0 SCREENING LEVEL ECOLOGICAL RISK ASSESSMENT

7.1 INTRODUCTION

This screening-level ecological risk assessment was conducted in accordance with USEPA Ecological Risk Assessment Guidance for Superfund (USEPA, 1997), USEPA Amended Guidance on Ecological Risk Assessment at Military Bases (USEPA, 2000a), and the Navy Policy for Conducting Ecological Risk Assessments (DON, 1999). The risk assessment for IR Site 46, consists of Steps 1 through 3A of USEPA's 8-step ecological risk assessment process. Steps 1 through 3A consist of the following:

Step 1 Screening-Level Problem Formulation and Ecological Effects Evaluation
Step 2 Screening-Level Exposure Estimate and Risk COPC of Potential Concern

Section 7.2.1 provides the environmental setting and summarizes the site history for Site 46. The fate and transport characteristics of the chemicals detected in surface soil and groundwater are provided in Section 7.2.2. The ecotoxicity of site contaminants and potential ecological receptors are described in Section 7.2.3. Section 7.2.4 describes complete exposure pathways and preliminary assessment and measurement endpoints are discussed in Section 7.2.5. Sections 7.3, 7.4, and 7.5 describe the screening level ecological effects evaluation, exposure estimates, and risk characterization, respectively. Section 7.6 describes the refinement of preliminary COPCs. Uncertainties inherent with the ecological risk assessment are discussed in Section 7.7. The summary and conclusions of this ecological risk assessment are provided in Section 7.8.

7.2 SCREENING-LEVEL PROBLEM FORMULATION

The Problem Formulation presents the site history, describes physical and ecological characteristics of the site, identifies ecological receptors of concern, and provides the basis for selecting assessment and measurement endpoints. These items provide the information that will be used to develop the conceptual exposure model for the site.

7.2.1 Environmental Setting

The environmental setting is discussed in Section 1.2.

7.2.2 Contaminant Fate and Transport

Previous investigations have identified the potential sources of contamination at Site 46 as most likely associated with paint stripping operations and waste disposal practices related to these operations or

undocumented minor spills. The source and nature of materials, as well as the time of release, are unknown.

Potential contaminant release mechanisms at Site 46 include the mobilization of contaminants from wastes discharged directly to surface soil with impact to local groundwater by infiltration of precipitation and dissolution of soluble contaminants. Soluble constituents can be transported to the water table by rainwater infiltration, and may continue to migrate downgradient discharging into Pensacola Bay.

Transport is affected by the chemical and physical properties of both the soil and the contaminants. Currently erosion and overland transport of particulate matter from site surface soil do not appear to be important transport mechanisms at Site 46 due to the developed nature of the site. Past erosion and overland transport of surface soil via storm water runoff as well as airborne dispersion by wind may have resulted in contaminant transport and deposition. Sources outside of Site 46 may also be responsible for contamination found in soil and groundwater.

The following discussions address classes of contaminants detected in surface soil and groundwater that might be associated with Site 46.

7.2.2.1 VOCs

VOCs are poorly adsorbed to soil and sediment particles. Also, because they are very volatile, they typically are detected in surface water, surface soil, and sediment only at low concentrations. VOCs in soil will dissolve in rain water to varying degrees and can be transported overland with runoff or into groundwater. Photolysis and hydrolysis are not significant mechanisms for VOC degradation. Aerobic biodegradation in soil and groundwater is significant, however, and anaerobic degradation can also occur in these media. VOCs do not bioaccumulate in ecological receptors, and therefore, biomagnification through the food chain is not significant. VOCs are typically toxic to ecological receptors only at relatively high concentrations.

7.2.2.2 SVOCs

Most SVOCs detected in Site 46 media were PAHs and phthalates. PAHs are a diverse group of compounds consisting of two or more substituted and unsubstituted polynuclear aromatic rings formed by the incomplete combustion of carbonaceous materials. PAHs are ubiquitous in the modern environment and are common constituents of coal tar, soot, vehicle exhaust, cigarette smoke, certain petroleum products, road tar, mineral oils, creosote, and many cooked foods. PAHs can also be released to the environment through natural sources such as forest fires. The fate and transport characteristics of PAHs are dependent on their molecular weights. Low molecular weight PAHs are more soluble and volatile, and therefore more mobile. They may volatilize and photolyze from soil and surface water, and they also

may be biodegraded. High molecular weight PAHs tend to be immobile and insoluble, binding strongly to organic matter (reducing the potential for leaching to groundwater), and they are resistant to volatilization, photolysis, and biodegradation (Eisler, 2000). Upper tropic level organisms are primarily exposed to PAHs through diet, but most wildlife can metabolize and excrete PAHs. Vertebrates can readily metabolize PAHs, but lower forms (insects and worms) cannot metabolize PAHs as quickly. USEPA Region IV considers the potential toxicity of PAHs via the terrestrial food web to be generally negligible unless PAHs are present at extremely high concentrations (i.e., percent levels: 10,000 mg/kg) in soil. Food chain uptake does not appear to be a major exposure source to PAHs, and food-chain biomagnification of PAHs is typically minimal (ATSDR, 1989a). PAHs may be absorbed by plants, but are expected to be translocated, metabolized, and potentially photodegraded. Accumulation within plants is likely to occur only in heavily polluted locations where uptake exceeds metabolism and degradation (Edwards, 1983).

One phthalate (bis[2-ethylhexyl]phthalate) was detected in groundwater. Plastic wastes are the major source of phthalates, which are relatively persistent in the environment. Although numerous studies have demonstrated that phthalates undergo biodegradation, this is a slow process. Some microorganisms have been shown to excrete products that increase the solubility of phthalates and enhance their biodegradation (Gibbons and Alexander, 1989). Adsorption onto soils and sediments appears to be a significant sink for phthalates. If released to water, phthalates tend to adsorb strongly to suspended particulate matter within the water column and sediment. Bis(2-ethylhexyl)phthalate is not expected to significantly volatilize or appreciably leach from soil into groundwater (Spectrum, 2003). Biomagnification of phthalates does not occur.

7.2.2.3 Pesticides

Chlorinated pesticides are highly persistent in the environment, and tend to tightly sorb to organic matter and be immobile in most soils. Although organic carbon was not analyzed in soil samples from Site 46, the sandy soils of northwest Florida are typically low in organic carbon content, which is presumably a major contributing factor in the migration of pesticides from soil into groundwater at the site. Degradation of chlorinated pesticides in soil would eventually occur through volatilization, photolysis, and aerobic and anaerobic degradation. Due to the lipophilicity of organochlorine pesticides, they can bioaccumulate in animals. These compounds generally bioconcentrate in lower trophic level organisms and can be transferred and magnified in higher trophic level organisms. Several chlorinated pesticides were detected in groundwater at Site 46.

7.2.2.4 PCBs

PCBs include a variety of mixtures of individual biphenyl isomers, each consisting of two joined benzene rings and up to 10 chlorine atoms. Mixtures of these isomers are known by their commercial designation of Aroclor. Only one PCB compound (Aroclor-1260) was detected in surface soil at Site 46.

PCBs adsorb strongly to soil particles with adsorption generally increasing with the degree of chlorination. PCBs generally do not significantly leach in aqueous soil systems. PCBs released into water adsorb to sediments and other organic matter. Typically, PCB concentrations are greater in sediment and suspended material than in the water column. Aquatic sediments can act as an environmental reservoir from which PCBs may be released slowly over a long period of time (ATSDR, 1989b). For PCBs that exist in the dissolved state in water, volatilization becomes the primary fate process (USEPA, 1985). Degradation of PCBs in the environment is dependent upon the degree of chlorination. Generally, the more chlorinated the PCB molecule, the more persistent it will be in the environment. Factors that determine biodegradability include the amount of chlorination, concentration, microbial population type, available nutrients, and the temperature (ATSDR, 1989b). Biodegradation of higher chlorinated PCBs (such as Aroclor-1260) occurs very slowly [Hazardous Substance Data Bank (HSDB), 2005]. PCBs can significantly bioconcentrate in aquatic organisms.

7.2.2.5 Metals

Metals released to soils will tend to remain in soils but may impact groundwater through infiltration and surface water through run off and erosion. Leaching of metals is more apt to occur under acid conditions in sandy soils with low organic matter content. Many metals occur naturally in soil, surface water, and sediment due primarily to chemical weathering of rocks. Factors such as pH, clay content, and organic matter content influence the bioavailability of metals to potential receptors. In water, most metals tend to adsorb to sediment or to suspended particles in the water column. However, because of dissolution, complexation, and sediment resuspension, metals are often detected in surface water. Arsenic, cadmium, chromium, copper, lead, mercury, silver, and zinc have the potential to bioaccumulate in biota (USEPA, 2000b).

7.2.3 Ecotoxicity

VOCs, SVOCs, pesticides, PCBs, and metals were detected in either surface soil or groundwater samples collected at Site 46. The following abstracts from the literature provide general discussions of each group's ecotoxicity.

7.2.3.1 VOCs

VOCs readily volatilize, are poorly adsorbed to soil and sediment particles, and are typically detected in surface water, surface soil, and sediment only at low concentrations. VOCs do not bioaccumulate in ecological receptors, and their toxicity to ecological receptors is relatively low.

7.2.3.2 SVOCs

Few generalizations can be made about the ecotoxicity of PAHs because of the extreme variability in toxicity and physiochemical properties of PAHs. Adverse impacts to plants from PAHs, however, are rare (Eisler, 2000). In most animal species, PAHs are metabolized by a mixed-function oxidase enzyme system into intermediates that may be toxic, mutagenic, or carcinogenic to the host. Some invertebrate species cannot efficiently metabolize PAHs (Eisler, 2000), and PAHs can be chronically toxic to invertebrates, but overall, very little is known about the toxicological mechanisms of PAHs in invertebrates (Erstfield and Snow-Ashbrook, 1999). PAHs can bind to cellular macromolecules and thereby disrupt their function in higher level organisms such as mammals and birds. Biological macromolecules include polymers of carbohydrates (e.g., starch), amino acids (proteins), and nucleotides (e.g., DNA). The cellular functions of these polymers include structure, energy storage, energy transfer, material transport, and the storage and transmittal of genetic information. PAHs show little tendency to biomagnify in the food web (Eisler, 2000). USEPA Region 4 considers the potential toxicity of PAHs via the terrestrial food web to be generally negligible unless PAHs are present at extremely high concentrations (i.e., percent levels: 10,000 mg/kg) in soil. Microbial metabolism is the major process for degradation of PAHs in soil (ATSDR, 1997).

Chronic oral exposure to phthalates can result in liver toxicity in mammals. Ingested phthalates metabolize to monoesters in the gut and are subsequently absorbed. Following absorption, phthalates distribute primarily to the liver and kidneys and may, in some species, concentrate in the testes (Rhodes et al., 1986). Liver carcinogenesis has been observed (ATSDR, 1997). Many receptors are able to metabolize and excrete phthalate esters, so their ability to bioaccumulate varies among species.

7.2.3.3 Pesticides

Organochlorine pesticides are reproductive and nervous system toxins. Although these compounds were used as insecticides, they are toxic to other animals as well. The target organ for acute exposures is the nervous system, while chronic exposures can affect the liver and endocrine systems of higher animals. Organochlorine pesticides are lipophilic and can be stored in the fat tissue of organisms such as birds and mammals. They can cause reproductive failure in birds of prey through eggshell thinning and

disruption of egg-laying and nesting cycles (Amdur et al., 1991). These pesticides were developed to control insects on crops, and as a result, they are practically non-toxic to plants.

7.2.3.4 PCBs

PCBs are highly lipophilic, and can bioaccumulate in animals. PCBs can accumulate in offspring through placental transfer in mammals and accumulation in bird eggs, and can accumulate in upper trophic level animals such as piscivorous birds and mammals that feed on contaminated prey items (Eisler, 2000). Toxicity to aquatic organisms can occur through chronic exposures to PCBs at the parts per billion level. In animals, the primary effect associated with PCB exposure is the induction of liver enzyme systems. These enzymes are associated with detoxification mechanisms and with the metabolism of hormones. Adverse reproductive effects observed with PCB exposure are associated with induction of the enzyme systems. The toxicity of PCBs to mammals and birds varies, depending on the particular PCB and the animal species. Mink, for example, are highly sensitive to PCBs. Impacts to mink include anorexia, weight loss, lethargy, reproductive effects, and death (Eisler, 2000). Among sensitive avian species, PCBs disrupt the normal pattern of growth, reproduction, metabolism, and behavior. PCBs are not water soluble and accumulate to a much greater degree in animals than in plants. Nevertheless, plant-related effects of PCB exposure can include slower growth, reduced chlorophyll content, and diminished photosynthesis (USEPA, 1999b).

7.2.3.5 Metals

It is difficult to make generalizations about the toxic actions of metals because of diverse affinities for organic molecules in biological structures, a wide array of biological effects, and a multiplicity of target organs and systems (Amdur et al., 1991). At the molecular level, metals can manifest toxicity in many ways, including selectively accumulating in target organs (such as the kidneys), substituting for essential metals, and mimicking essential substrates (Clarkson, 1983). At the molecular level, metal toxicity typically affects enzyme systems, leading to disruption of cellular transport, cellular respiration, cell division, and other physiological processes. Metal toxicity to aquatic organisms is marked by a broad spectrum of effects that can range from reduced growth to death. Aquatic organisms are most sensitive to metal toxicity in the embryonic and larval stages of the life cycle.

7.2.4 Complete Exposure Pathways

Soil invertebrates and plants are exposed to soil contaminants through ingestion and direct contact. No complete exposure pathways to higher trophic level animals are present at Site 46. Ground cover at the site is predominantly paved parking areas or buildings with little undisturbed native soils. The current land use discourages use of the site by birds and mammals except as occasional transients. The exposure of higher trophic level animals such as birds and mammals to site-related contamination

through ingestion of contaminated food items is therefore considered unlikely due to the absence of habitat at Site 46. Consequently, this is not considered to be a complete exposure pathway. Similarly, the incidentally ingestion of soil contaminants while preening feathers is not considered a significant source of potential exposure as birds are not anticipated to reside at the site or be present for extended periods of time. Exposure to contaminants in soil through dermal contact could occur but is unlikely to represent a major exposure pathway because feathers and chitinous exoskeletons minimize transfer of contaminants across dermal tissue. Airborne transport is a negligible pathway consequently the inhalation pathway is not significant. Exposure to contaminants in groundwater is not anticipated to occur at Site 46. Potential exposure to groundwater contaminants discharged to surface water has been addressed in the risk assessment performed for IR Site 2.

Actual or potential exposures of ecological receptors are determined by identifying the most likely pathways of contaminant release and transport. A complete exposure pathway has three components: (1) a source of chemicals that can be released to the environment, (2) a route of contaminant transport through an environmental medium, and (3) an exposure or contact point for an ecological receptor. As explained in Step 1 of USEPA's ecological risk assessment guidance (USEPA, 1997), if an exposure pathway is not complete, that exposure pathway does not need to be evaluated. In summary, complete exposure pathways and routes of entry into biota at Site 46 consist of:

- Direct contact with surface soil by invertebrates and plants
- Ingestion of surface soil by invertebrates

7.2.5 Preliminary Assessment and Measurement Endpoints

USEPA Region IV has specified that assessment endpoints for the screening-level assessment should be broad and generic. For the screening level assessment, the preliminary assessment endpoint is the protection of terrestrial biota from adverse effects of chemicals on their growth, survival, and reproduction. Measurement endpoints represent the assessment endpoints chosen for a site, and are measures of biological effects (USEPA, 1997). The preliminary measurement endpoints were chemical concentrations in surface soil that are associated with no adverse effects on growth, survival, and reproduction of terrestrial organisms. The measurement endpoints are represented by USEPA Region IV ecological screening values (ESVs) for surface soil. USEPA Ecological Soil Screening Levels (Eco-SSLs) were used in place of the USEPA Region IV ESVs as the measurement endpoints for chemicals when Eco-SSLs were available.

The USEPA Region IV ESVs for surface soil are based on conservative endpoints and sensitive ecological effects data, and thus, the screening values represent chemical concentrations associated with a low probability of unacceptable risks to ecological receptors. For this reason, USEPA Region IV

considers their soil ESVs to be protective of terrestrial invertebrates and plants as well as upper level receptors such as birds and mammals. Additionally, the lowest of the plant, invertebrate, mammal, and avian Eco-SSL was used for chemicals when Eco-SSLs were available. In the screening level ecological risk assessment, a distinction is not made between measurement endpoints associated with direct toxicity to invertebrates and plants versus measurement endpoints associated with food chain effects.

7.3 SCREENING-LEVEL ECOLOGICAL EFFECTS EVALUATION

For the screening level ecological risk assessment, maximum concentrations of chemicals detected in surface soil were compared to Eco-SSLs for chemicals which Eco-SSLs are available and to USEPA Region IV ESVs (USEPA, 2001) for all other detected chemicals. If the maximum concentration was less than the Eco-SSL (or the ESV), the chemical was eliminated from further consideration. If the maximum concentration equaled or exceeded the screening level, or if a screening level was not available, the chemical was then considered to be an ecological COPC and was retained for further study in the ecological risk assessment.

Groundwater concentrations were compared to USEPA Region IV surface water screening levels as a very conservative measure of potential impacts to ecological receptors from contaminated groundwater. Analytes in groundwater that exceed surface water ESVs or lack ESVs are not selected as COPCs but are listed for informational purposes. This analysis is considered extremely conservative as it does not take into account dilution at the discharge point(s), which may be substantial, the amount of discharge, location of the point(s) of discharge, or direction of groundwater flow. Exposure of ecological receptors after groundwater discharges directly to surface water was previously evaluated as part of the surface water pathway in the IR Site 2 risk assessment.

7.4 SCREENING-LEVEL EXPOSURE ESTIMATE

Exposure point chemical concentrations were obtained from surface soil and groundwater samples collected in October and December 2005. The data are presented in Section 4 (Tables 4-3 through 4-8).

The surface soil data base consisted of three samples (and one duplicate sample) analyzed for VOCs, SVOCs, pesticides and PCBs, inorganics, and petroleum hydrocarbons, in addition to 28 soil screening samples analyzed for lead, aluminum, and iron. All samples were collected from a depth of 0 to 0.5 feet bls between October 19th and December 2nd, 2005. Figure 2-1 in Section 2 illustrates where surface soil samples were collected.

The groundwater data base consisted of 20 samples and three duplicate samples analyzed for VOCs, SVOCs, pesticides and PCBs, inorganics, and petroleum hydrocarbons. All samples were collected

between December 18th and December 20th, 2005. Figure 2-2 in Section 2 illustrates the locations of the groundwater samples.

All analytes (except calcium, magnesium, potassium, sodium,) detected in surface soil and groundwater samples were assessed in this investigation. Calcium, magnesium, potassium, and sodium were excluded because they are essential nutrients that are toxic only at extremely high concentrations. Due to the scarcity of data for these essential nutrients, it was not possible to develop ranges of toxicity for them even at high concentrations.

7.5 SCREENING-LEVEL RISK CALCULATION

The preliminary risk calculation step compared maximum concentrations of chemicals in surface soil to USEPA Eco-SSLs and USEPA Region IV ESVs. The ratio of the maximum concentration to the ESV is called the screening HQ. Analytes whose maximum concentrations equaled or exceeded ESVs (i.e., HQ $\geq$ 1.0), or did not have ESVs, were retained as ecological COPCs. Although ecological receptors are not directly exposed to groundwater contaminants, groundwater data were compared to surface water screening values as a conservative measure of potential impacts to aquatic media from contaminated groundwater discharge but not for COPC selection. Due to the fact that groundwater at Site 46 discharges into Pensacola Bay, salt water ESVs were used for the comparison.

7.5.1 Surface Soil

In surface soil, five VOCs (1,2-dichlorobenzene, 1,4-dichlorobenzene, chloromethane, PCE, and TCE) were retained as COPCs because their maximum concentrations exceeded screening values (Table 7-1). The VOC acetone was retained as a COPC because an ESV is not available. One SVOC (phenol) was retained as a COPC because its maximum concentration exceeded the corresponding ESV, while nine PAHs (2-methylnapthalene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluorene, and ideno(1,2,3-cd)pyrene) were retained as COPCs because ESVs were not available. It should be noted that the maximum concentration of total PAHs (the total of anthracene, benzo(a)anthracene, benzo(k)fluoranthene, benzo(a)pyrene, chrysene, phenanthrene, fluoranthene, indeno(1,2,3-cd)pyrene, naphthalene and benzo(ghi)perylene) was less than its corresponding USEPA Region IV ESV. The PCB Aroclor-1260 was also retained as a COPC because its maximum concentration exceeded the USEPA Region IV ESV for total PCB.

Six metals (aluminum, cadmium, chromium, iron, lead, and zinc) were retained as COPCs because their maximum concentrations exceeded their respective Region IV ESVs or Eco SSLs.

TPH are retained as a COPC because no Region IV ESV is available.

7.5.2 Groundwater

Surface (salt) water ESVs were not available for 14 of the VOCs detected in groundwater. The four remaining VOCs had maximum concentrations in groundwater less than their corresponding salt water ESVs (Table 7-2). One SVOC (naphthalene) had a maximum groundwater concentration that exceeded the salt water ESV. Three SVOCs (2-methylnapthalene, fluorene, and bis(2-ethylhexylphthalate) had no salt water ESV. Three pesticides (alpha-and gamma-chlordane, and gamma-BHC) had maximum groundwater concentrations that exceeded the respective salt water ESVs. Six metals (chromium, copper, lead, nickel, silver, and zinc) had maximum groundwater concentrations in excess of corresponding salt water ESVs. Seven inorganic compounds detected in groundwater (aluminum, barium, beryllium, cobalt, iron, manganese, and vanadium) had no salt water ESVs. No Region IV ESV is available for TPH.

7.6 REFINEMENT OF PRELIMINARY COPCs

At this point, the first two steps of the ecological risk assessment have been completed. The ecological risk assessment process includes a series of scientific/management decision points (SMDPs) (USEPA, 1997). The first SMDP occurs at the end of Step 2, and requires the risk managers to evaluate and approve or redirect the work up to that point and determine whether the risk assessment will continue into Step 3. However, USEPA Region IV recognizes that most ecological risk assessments will proceed into Step 3, and facilities are encouraged to submit the results of Steps 1-3 as a single deliverable document (USEPA, 2000a). With this in mind, and since the screening level ecological risk assessment indicates a potential for adverse effects, a more thorough assessment is warranted. Therefore, the risk assessment process for Site 46 will proceed into Step 3 (Baseline Risk Assessment Problem Formulation).

The baseline ecological risk assessment begins with a more balanced evaluation of the conservativeness inherent in the first two steps of the risk assessment process (USEPA, 1997; DON, 1999). The initial phase of Step 3 is typically known as Step 3A, and consists of a refinement of the conservative exposure assumptions in order to more realistically estimate potential risks to ecological receptors (i.e., plants and invertebrates). Examples of factors considered during Step 3A include toxicological evaluation of COPCs, frequency of detection and spatial distribution of contaminants, comparison to background, and consideration of habitat quality (USEPA, 1997; USEPA 2000a, DON, 1999).

Food-chain modeling was not conducted for the Site 46 screening level ecological risk assessmen due to the absence of upper trophic level receptors associated with the poor habitat quality found at the site.

The area of investigation is industrial in nature with disturbed soils classified as urban that have been paved or built upon. Wildlife species are unlikely to reside or feed at Site 46 and are more likely to be transient in route to the habitat south of the site associated with Pensacola Bay. The Pensacola Bay habitat south of Site 46 was previously assessed during the IR Site 2 investigation.

7.6.1 Step 3A Discussion

The results of the screening level assessment and Step 3A considerations are discussed on a COPC-specific basis.

7.6.1.1 VOCs

One VOC (acetone) was retained as a COPC in surface soil because an USEPA Region IV ESV was not available. Acetone is a known laboratory contaminant however, it is also a solvent used in painting so the potential exists that it may be site-related. The toxicity of acetone to animals is in the parts-per-thousand range (Opresko, 1995). The highest concentration of acetone (26 mg/kg) was found at sample location 46SB2901. Detected concentrations of acetone at all other locations were much lower (0.012 mg/kg - 0.022 mg/kg). Although toxicity data is sparse regarding its effects to invertebrates and plants, the presence of acetone at relatively low concentrations in soil probably poses negligible or minor risk.

1,2-dichlorobenzene and 1,4-dichlorobenzene were each detected in only 1 of 16 samples (46SB3401) at concentrations above the USEPA Region IV ESV for dichlorobenzene (0.01 mg/kg). The detected 1,2- and 1,4-dichlorobenzene concentrations were compared to the following toxicity guidelines to further evaluate potential risks to plants and invertebrates.

- Dutch Target Value (for chlorobenzenes sum) 0.03 mg/kg, Intervention Value 30 mg/kg. Intermediate Value 15.02 mg/kg (MVROM, 2000).
- Lowest Oak Ridge National Laboratory (ORNL) Screening Benchmark for 1,4-dichlorobenzene 20 mg/kg (based on earthworm toxicity).

The Dutch target values represent clean soil, the intervention value represents seriously contaminated soil, and the concentration midway between the target value and the intervention value is designated as an “intermediate” value. The Dutch guidelines specify that concentrations greater than the target value, but less than the intermediate value require no further investigation (but minor restrictions may be applied on soil use), while further investigation is required when concentrations exceed the intermediate value but are less than the intervention value (Swartjes, 1999).

The Dutch values are for chlorobenzene (sum) which is defined as the total of all mono-, di-, tri-, tetra, penta-, and hexachlorobenzenes. The total dichlorobenzene concentration is 0.28 mg/kg. This concentration is greater than the Dutch Target, but less than the Intermediate and Intervention Value.

ORNL developed soil screening benchmarks based on toxicity of chemicals to plants, earthworms, soil microorganisms and microbial processes (Efroymson et al., 1997a; Efroymson, Will, and Suter 1997b). The lowest of these values is used to be conservative. The concentration of 1,4-dichlorobenzene (0.11 mg/kg) is well below the ORNL benchmark for 1,4-dichlorobenzene (20 mg/kg) as is the concentration of 1,2-dichlorbenzene (0.17 mg/kg). The total dichlorobenzene concentration (0.28 mg/kg) is also less than the ORNL benchmark for 1,4-dichlorobenzene. Based on the comparison to Dutch and ORNL benchmarks, potential risk to soil invertebrates is considered minimal and spatially limited to location 46SB3401.

No USEPA Region IV ESV was found specifically for chloromethane so the ESV for aliphatic chlorinated hydrocarbons was used (0.1 mg/kg). This ESV is based on a US Fish and Wildlife Service document (Beyer, 1990) that identifies three categories of soil contamination labeled A, B, and C. A refers to background concentrations in soil or detection limits, B refers to moderate soil contamination that requires additional study, and C refers to threshold values that require immediate cleanup. The USEPA Region IV ESV for aliphatic chlorinated hydrocarbons (0.1 mg/kg) is the Beyer A value. The corresponding B and C values are 5 mg/kg and 50 mg/kg respectively. The maximum concentration of chloromethane (0.28 mg/kg) is well below the Beyer B and C values. All other detected concentrations of chloromethane were less than the USEPA Region IV ESV for aliphatic chlorinated hydrocarbons. Based on this information, potential risk to plants and soil invertebrates from chloromethane is considered minimal.

PCE was detected in 2 of 15 soil samples at or above its ESV (0.1 mg/kg). Sample location 46SB3401 had the highest concentration of 0.1 mg/kg while sample 46SB3101 had the lowest reported detected concentration of 0.006 mg/kg. The detected PCE concentrations were compared to the following toxicity guidelines to further evaluate risks to plants and invertebrates.

- Canadian Soil Quality Guideline (SQG): 3.8 mg/kg agricultural use (CCME, 1999a)
- Dutch Target Value 0.002 mg/kg, Intervention Value 4 mg/kg (MVROM, 2000)

The Canadian SQG of 3.8 mg/kg for PCE is the 25th percentile of effects and no effects data distribution for plants and invertebrates (CCME, 1999a). The maximum detected concentration of PCE at Site 46 is well below the Canadian Soil Quality Guideline for agricultural use, and for residential parkland use (3.8 mg/kg). Both of the detected concentrations of PCE also exceeded the Dutch Target Value. The intermediate value, as described previously, for PCE is 2.001 mg/kg. Both detected concentrations are

well below this benchmark. Therefore, because the detected concentrations are below these benchmarks, risk to plants and soil invertebrates from PCE are expected to be minimal.

TCE was detected in 7 of 16 soil samples at or above its ESV (0.001 mg/kg). Sample location 46SB2901 had the highest concentration of 150 mg/kg while sample 46SB4201 had the lowest reported detected concentration of 0.001 mg/kg. The detected TCE concentrations were compared to the following toxicity guidelines to further evaluate risks to plants and invertebrates.

- Canadian Soil Quality Guideline (SQG): 3 mg/kg agricultural use (CCME, 1999a)
- Dutch Target Value 0.1 mg/kg, Intervention Value 60 mg/kg (MVROM, 2000)

The Canadian SQG of 3 mg/kg for TCE is the 25th percentile of effects and no effects data distribution for plants and invertebrates, and corresponds to an effect on radish seedling emergence (CCME, 1999a). The maximum detected concentration of TCE at Site 46 exceeded the Canadian Soil Quality Guideline for agricultural use, and for Industrial Land use (31 mg/kg). The detected concentrations of TCE also exceeded the Dutch Target Value, and the maximum concentration exceeded the Dutch Intervention Value. One other sample (46SB3301) also exceeded the Canadian SQG and the Dutch Intermediate value of 30.05 mg/kg. These results indicate potential risk to plants and soil invertebrates from TCE particularly in the area of sample 46SB2901.

Twelve VOCs detected in groundwater had no USEPA Region IV ESVs for comparison. All of these compounds were detected at low concentrations. In the absence of USEPA Region IV ESVs, supplemental surface water screening values were researched. Additional sources for surface water guidelines include secondary chronic and acute values calculated by the ORNL (Suter and Tsao, 1996), using methods developed by the USEPA (USEPA,1993) for the Great Lakes. The methods developed for calculating secondary, or Tier II, values were designed for instances were there were some acceptable toxicity data for a chemical, but not enough to satisfy the requirements for calculating water quality criteria, or Tier I values. “The Tier II methodology generally produces more stringent values than the Tier I methodology, to reflect greater uncertainty in the absence of additional toxicity data (USEPA, 1993).” ORNL used methods similar to the USEPA in qualifying toxicological data for inclusion in the Tier II calculations. Both the USEPA and ORNL used primarily effect level values from 48- and 96-hour acute tests to set water quality criteria and secondary values. Chronic values are usually developed from acute values using acute-chronic ratios based on tests incorporating both types of endpoints and performed in a similar manner. It should be noted that the secondary chronic values (SCVs) are freshwater values. The following SCVs were identified for VOCs detected in groundwater that have no USEPA Region IV ESVs:

- 1,1-DCA SCV 47 µg/L
- Carbon Disulfide SCV 0.92 µg/L
- 1,2-DCE SCV 590 µg/L
- TCE SCV 47 µg/L
- Xylenes SCV 13 µg/L

All detected groundwater concentrations of the above compounds are less than their corresponding SCVs. There is uncertainty regarding potential risk associated with those compounds for which no ESVs are available; however, as previously discussed, the screening of contaminants in groundwater was performed for informational purposes and not COPC selection. The low detected VOC concentrations should become even more dilute upon discharge to Pensacola Bay and are not expected to be associated with unacceptable risk.

TPH was retained as a COPC in both surface soil and groundwater as no USEPA Region IV ESV is available. It should be noted that TPH is a general term used to describe a large family of several hundred chemical compounds that originally come from crude oil. Because there are so many different chemicals in crude oil and in other petroleum products, it is not practical to measure each one separately (ATSDR, 1999). TPH is therefore a general parameter used to evaluate potential soil and groundwater contamination from petroleum products such as gasoline, fuel oils, mineral oils, and jet fuel. As a gross measure of petroleum contamination, TPH results simply show that petroleum hydrocarbons are present in the sampled media. Many of the individual components of TPH have been evaluated for potential ecological risk at Site 46 such as benzene, toluene, ethylbenzene, xylenes, naphthalene, and PAHs. TPH is therefore not considered a COPC.

7.6.1.2 SVOCs

One SVOC (phenol) was retained as a COPC in surface soil because the maximum concentration (0.36 mg/kg) exceeded the 0.05 mg/kg ESV (HQ = 7.2). Phenol was detected in only one of three samples at location 46SB2901. The detected phenol concentration was compared to the following toxicity guidelines to further evaluate risks to plants and invertebrates.

- Canadian SQG: 20 mg/kg agricultural use (CCME, 1999b)
- Dutch Target Value 0.05 mg/kg, Intervention Value 40 mg/kg (MVROM, 2000)

The Canadian SQG of 20 mg/kg for phenol was calculated by dividing the lowest observable effect concentration (LOEC) of 79 mg/kg phenol from a study of lettuce seedling emergence by an uncertainty factor of 4 (=19.75 mg/kg) rounded up to 20 mg/kg (CCME, 1999b). The maximum detected concentration of phenol is much less than the Canadian SQG. The Dutch Target Value (0.05 mg/kg) is

the value used by USEPA Region IV as the ESV. The maximum concentration of phenol is greater than the Target value but much less than the Intervention and Intermediate Value of 20 mg/kg. Based on the low concentrations found and comparison to the Canadian and Dutch guidelines, potential risk from phenol in surface soil is considered minimal.

Nine PAHs (2-methylnapthalene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluorene, and ideno(1,2,3-cd)pyrene) were retained as COPCs in surface soil because USEPA Region IV ESVs were not available. Ecologically-based toxicity values are sparse for PAHs in soil, and USEPA Region IV has established screening values for only 8 of the 17 individual PAHs detected at the site. The Canadian SQG recommends individual soil screening values of 0.1 mg/kg for benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene for the protection of the environment and human health. The maximum detected concentrations of these PAHs are all below the Canadian SQG screening benchmarks (See Table 7-1). There fore the risks to plants and soil invertebrates from benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene are expected to be negligible.

The USEPA Region IV screening values for six of these eight PAHs are based on Dutch values established in the Netherlands during the 1980s. The Dutch screening values for total PAHs, include a Target value of 1 mg/kg and an Intervention value of 40 mg/kg for total PAHs (MHSP&E, 1994). The intermediate value for total PAHs in soil (i.e., the concentration midway between the target value and the intervention value) is 20 mg/kg.

An ecological screening value of 20.8 mg/kg for total PAHs was calculated by Lingenfelser (2000) for assessing risk to soil invertebrates. Lingenfelser's screening value was derived using toxicity equivalency factors and was based on a study by Neuhauser et al (1986) in which the effects of fluorene were evaluated using four species of earthworms. The similarity of Lingenfelser's screening value relative to the Dutch intermediate value provides credence for use of the Dutch value as a conservative screening value for total PAHs.

The toxicity of PAHs is often assumed to be additive, so evaluating PAH toxicity in soil by examining total PAH concentrations is especially useful when, as at Site 46, several PAHs were detected for which ecological screening values do not exist. The maximum concentration of total PAHs at Site 46 (0.181 mg/kg) was well below the USEPA Region IV ESV of 1 mg/kg, and was below both the 20 mg/kg Dutch intermediate value and the Lingenfelser (2000) soil invertebrate toxicity threshold value of 20.8 mg/kg. Thus, risks to plants and soil invertebrates from PAHs are negligible.

In groundwater, the maximum screening HQ of one PAH (naphthalene) exceeded 1.0, but was relatively low (10). All other detected concentrations of naphthalene (0.05 µg/L, 1 µg/L) were well below the USEPA Region IV ESV of 23.5 µg/L. Potential risks from naphthalene in groundwater are considered negligible.

USEPA Region IV salt water ESVs were not available for the PAHs 2-methylnapthalene and fluorene. In the absence of USEPA Region IV ESVs, Tier II SCVs (Suter and Tsao, 1996) were reviewed for applicable screening values. The following SCVs were identified:

- 1-Methylnapthalene SCV 2.1 µg/L
- Fluorene SCV 3.9 µg/L

All detected concentrations of 2-methylnapthalene in groundwater except the maximum are below the SCV for 1-methylnapthalene. All detected concentrations of fluorene in groundwater are below the SCV. Potential risks from these PAHs in groundwater are therefore considered negligible.

Bis(2-ethylhexyl)phthalate has no USEPA Region IV ESV. Bis(2-ethylhexyl)phthalate was detected in only 1 of 27 samples (46GW1401). Bis(2-ethylhexyl)phthalate was not detected in the duplicate for this sample (46GW1401-D). Phthalates are common environmental contaminants due to their use in plastics. Phthalates can also be an artifact of the sampling and/or analytical methods. Even though the maximum reported concentration of bis(2-ethylhexyl)phthalate (64 µg/L) exceeds the ORNL (Suter and Tsao, 1996) Tier II SCV (3.0 µg/L), potential risk is considered negligible.

7.6.1.3 Pesticides

Pesticides were not detected in the surface soil samples at Site 46 but several pesticides were detected in groundwater. All pesticide COPCs at Site 46 are organochlorine insecticides that are no longer used but are known to be extremely persistent in the environment. Detected concentrations of alpha and gamma-Chlordane and gamma-BHC detected in groundwater exceeded the USEPA Region IV salt water ESVs; however, they were detected in very few samples. Alpha-Chlordane was detected in 2 of 24 samples at locations 46GW0601 and 46GW0701, and gamma-Chlordane was detected in 1 of 24 samples at 46 GW0701. Gamma-BHC was detected in 1 of 24 samples at 46GW1901. Due to the low frequency of detection and the low concentrations detected (0.031 – 0.17 µg/L), and the fact that these concentrations should be less upon discharge and dilution in Pensacola Bay, potential risk from chlorinated pesticides is considered negligible.

7.6.1.4 PCBs

The PCB Aroclor-1260 was detected in 1 of 3 surface soil samples at a concentration (0.36 mg/kg) in excess of the USEPA Region IV ESV (0.02 mg/kg) resulting in a maximum screening HQ of 18. All other samples were reported as non-detected. To provide perspective, the detected Aroclor-1260 concentration was compared to the following toxicity guidelines to further evaluate risks to plants and invertebrates.

- Canadian SQG for PCBs 0.5 mg/kg agricultural use (CCME, 2001)
- Dutch Target Value for Total PCB 0.02 mg/kg, Intervention Value 1 mg/kg (MVROM, 2000)

The detected Aroclor-1260 concentration is less than the Canadian SQG (interim soil quality criterion from CCME, 1991) and the Dutch Intervention Value. While it is greater than the Dutch Target Value, it is less than the intermediate Total PCB value of 0.51 mg/kg. ORNL developed soil screening benchmarks based on toxicity of chemicals to plants, earthworms, soil microorganisms and microbial processes (Efroymson et al., 1997a; Efroymson, Will, and Suter 1997b). The lowest of these values is used to be conservative. The following ORNL value was identified for PCBs:

- ORNL Screening Benchmark for phytotoxicity 40 mg/kg

The detected concentration of Aroclor-1260 is much less than this benchmark. Based on the concentration of Aroclor-1260 detected, its frequency of detection, and the comparison to benchmarks, potential risk from PCBs in surface soil at Site 46 is considered minimal.

7.6.1.5 Metals

Aluminum, cadmium, chromium, iron, lead, and zinc were retained as COPCs in surface soil because their maximum concentrations exceeded their respective Region IV ESVs or Eco SSLs. As previously discussed, where Eco SSLs were available, the lowest value for invertebrate, plant, avian, or mammal was used. Three metals (cadmium, chromium, and lead) were identified as COPCs based on comparisons to Eco SSLs for avian or mammalian endpoints. The preliminary assessment endpoint for the screening-level ecological risk assessment is the protection of plants and soil invertebrates from adverse effects of chemicals on their growth, survival, and reproduction. The use of Eco SSLs based on avian or mammalian endpoints may be overly conservative when Eco SSLs for the specified assessment endpoints are available.

Cadmium was detected in only one of three surface soil samples. A mammalian Eco SSL of 0.36 mg/kg was used as the ESV for cadmium (USEPA, 2005a). The soil invertebrate Eco SSL is 140 mg/kg and the

plant Eco SSL is 32 mg/kg. The maximum surface soil concentration (1.2 mg/kg) is much less than the invertebrate and plant values so risk from cadmium is considered negligible.

Chromium was detected in three of three surface soil samples at Site 46. Only the maximum concentration (28.2 mg/kg) exceeded the USEPA Region IV ESV. The lowest Eco SSL for chromium (USEPA, 2005b) used as the ESV (26 mg/kg) in the screening is an avian value for trivalent chromium (chromium^{+3}). The maximum concentration of chromium in surface soil is less than the lowest Eco SSL value (81 mg/kg) for hexavalent chromium (chromium^{+6}). Chromium^{+6} is the form of chromium typically considered in screening level ecological risk assessments due to its toxicity. Although no Eco SSLs are available for soil invertebrates or plants, potential risk from chromium is considered negligible.

Lead was detected in 31 of 31 surface soil samples collected during screening and characterization activities. Lead exceeded the USEPA Region IV ESV in 25 of 31 samples. The ESV (11 mg/kg) is based on an Eco SSL for avian receptors (USEPA, 2005c). The corresponding Eco SSL for soil invertebrates is 1700 mg/kg while the Eco SSL for plants is 120 mg/kg. No surface soil concentrations exceeded the Eco SSL for invertebrates. The plant Eco SSL was exceeded at five locations (46SB0101, 46SB1501, 46SB2101, 46SB2501, and 46SB2701). HQs calculated using the Eco SSL for plants and the concentrations corresponding to the above listed locations range from 1.1 to 5.1. Overall, potential risk to plants from lead in surface soil appears minor and potential risk to soil invertebrates negligible.

Zinc was detected in three of three surface soil samples but exceeded the USEPA Region IV ESV (50 mg/kg) in only one sample (46SB3001, at 137 mg/kg). The USEPA Region IV ESV for zinc is based on the lowest ORNL screening benchmark (Efroymson et al., 1997a; Efroymson, Will, and Suter 1997b) and is based on toxicity to plants. The ORNL screening benchmark for earthworms (200 mg/kg) was not exceeded by any sample indicating negligible risk to soil invertebrates.

To further evaluate potential risk to plants, detected zinc concentrations were compared to the following toxicity guidelines to further evaluate potential risks to plants and invertebrates.

- Canadian SQG for zinc 600 mg/kg agricultural use (CCME, 1999c)
- Dutch Target Value for zinc 120 mg/kg, Intervention Value 720 mg/kg, Intermediate Value 420 mg/kg (MVROM, 2000)

The Canadian SQG is based on a LOEC from a test on seedling emergence in radish. No samples had concentrations of zinc that exceeded the Canadian SQG. The maximum concentration of zinc did exceed the Dutch Target Value but was less than the Intermediate and Intervention Values. Based on the fact

that only one sample exceeded the Region IV ESV and the comparison to the Canadian and Dutch guidelines, potential risk from zinc to plants is considered to be minimal.

Aluminum exceeded the USEPA Region IV ESV (50 mg/kg) in 27 of 31 surface soil samples and iron exceeded its USEPA Region IV ESV (200 mg/kg) in 28 of 31 samples. The USEPA Region IV ESVs for aluminum and iron are from the ORNL screening benchmarks (Efroymson et al., 1997a; Efroymson, Will, and Suter 1997b). The ESV for aluminum is based on toxicity to plants, while the ESV for iron is based on toxicity to soil microorganisms and microbial processes. USEPA Eco SSLs for aluminum and iron are not available. The Eco SSL document for aluminum (USEPA, 2003a) indicates that the typical range of aluminum in soils is from 1 percent to 30 percent (10,000 to 300,000 mg/kg) with naturally occurring concentrations varying over several orders of magnitude. The detected concentrations of aluminum at Site 46 range from 116 mg/kg to 24,500 mg/kg which falls within the cited range; however, the majority of aluminum concentrations exceed the NAS Pensacola Reference Concentration for aluminum in surface soil (3,883 mg/kg). The Eco SSL further states that because the measurement of total aluminum in soils is not considered suitable or reliable for the prediction of potential toxicity and bioaccumulation, an alternative (not concentration-based) procedure is recommended for screening aluminum in soils. The conclusion in the Eco SSL document is that aluminum is a COPC only at sites where the soil pH is less than 5.5. In the absence of soil pH data, there is uncertainty regarding potential ecological risk from aluminum however, based on the typical range of aluminum in surface soil cited in the Eco SSL (USEPA, 2003a), any risk from aluminum is considered to be negligible or minor at worst.

The USEPA Eco SSL document for iron states that identifying a specific benchmark for iron in soils is difficult because iron's bioavailability to plants and resulting toxicity are dependent upon site-specific soil conditions (USEPA, 2003b). The document indicates that typical iron concentrations in soils range from 0.2 to 55 percent (2,000 to 550,000 mg/kg) and concentrations can vary significantly, even within localized areas, due to soil types and the presence of other sources. Iron concentrations at Site 46 ranged from 50.6 mg/kg to 13,700 mg/kg which is below the lower end of the cited range; however, half of the samples had concentrations greater than the NAS Pensacola reference concentration (2,745 mg/kg). As discussed in the Eco SSL document, iron is essential for plant growth and is generally considered to be a micronutrient and is considered the key metal in energy transformations needed for syntheses and other life processes of the cells. In well-aerated soils between pH 5 and 8, the iron demand of plants is higher than the amount available. Because of this limitation, plants have evolved various mechanisms to enhance iron uptake. Under these soil conditions, iron is not expected to be toxic to plants. In the absence of soil pH data, there is uncertainty regarding potential ecological risk from iron; however, based on the typical range of iron in surface soil cited in the Eco SSL (USEPA, 2003b), any risk from iron is considered to be negligible.

Six metals (chromium VI, copper, lead, nickel, silver, and zinc) had maximum groundwater concentrations in excess of corresponding USEPA Region IV salt water ESVs. Each of these metals is addressed individually below.

Chromium was detected in 12 of 26 groundwater samples. Only 3 of these 12 samples had concentrations (52.3 µg/L, 75 µg/L, and 244 µg/L) in excess of the USEPA Region IV salt water ESV of 50 µg/L for chromium^{+6}. No USEPA Region IV salt water ESV is available for chromium^{+3}; however, no sample exceeded the USEPA Region IV fresh water ESV for chromium^{+3} (644 µg/L). The freshwater ESV was calculated using an equation provided with the USEPA Region IV ESVs for metals whose ESVs are hardness dependent. The equation used is based on a hardness range of 25 mg/L to 400 mg/L as calcium carbonate. As the maximum hardness in Site 46 groundwater exceeded the upper end of this range (1482 mg/L) a maximum hardness value of 400 mg/L was used to calculate the ESV. The ESVs for chromium are expressed as dissolved metal in the water column while the groundwater data is for total metal. The dissolved fraction would be anticipated to be present at a lower concentration. Based on this and the fact that dilution upon discharge into Pensacola Bay is not considered, chromium in groundwater is considered to pose negligible risk.

Copper was detected in 2 of 26 groundwater samples. The maximum concentration (97.8 µg/L) was detected in the duplicate of sample 46GW2001. Sample 46GW2001 was reported as non-detected for copper. There is uncertainty in the results for these samples. Sample 46GW1601 had a reported copper concentration (20.2 µg/L) that is greater than the USEPA Region IV salt water ESV (2.9 µg/L). Only the maximum detected concentration (sample 46GW2001-D) exceeded the USEPA Region IV fresh water ESV for copper (38.66 µg/L) based on a maximum hardness of 400mg/L. The USEPA Region IV ESV is based on dissolved metal while the results reflect total metals. As previously discussed the dissolved fraction would be less. Due to the low concentrations, low frequency of detection and considering potential dilution upon discharge, copper is considered to pose negligible risk.

Lead was detected in 15 of 26 groundwater samples. Of these 15 samples, only one sample (38GW1SO01 at 23.7 µg/L) exceeded the USEPA Region IV ESV (8.5 µg/L). The USEPA Region IV ESV is based on dissolved metal while the results reflect total metals. As previously discussed the dissolved fraction would be less. Due to the low concentrations, low frequency of detection and considering potential dilution upon discharge, lead is considered to pose negligible risk.

Nickel was detected in 12 of 26 groundwater samples but only two of these samples had concentrations (17.8 µg/L-31.3 µg/L) in excess of the USEPA Region IV salt water ESV (8.3 µg/L). All detected concentrations were less than the USEPA Region IV fresh water ESV (509.42 µg/L) based on a maximum hardness of 400mg/L. The USEPA Region IV ESV is based on dissolved metal while the

results reflect total metals. As previously discussed the dissolved fraction would be less. The NAS Pensacola Reference Concentration for nickel is 39.9 µg/L. All detected concentrations of nickel in groundwater are less than the reference concentration. Due to the low concentrations and considering potential dilution upon discharge, nickel is considered to pose negligible risk.

Silver was detected in only 1 of 26 groundwater samples at a concentration (4.5 µg/L) slightly above the detection limit (4.4 µg/L). This concentration is greater than the USEPA Region IV salt water ESV (0.23 µg/L) and the USEPA Region IV fresh water chronic ESV (0.012 µg/L). No other salt water screening values were identified but an ORNL Secondary Chronic Value (Suter and Tsao, 1996) for silver in fresh water was available (0.36 µg/L). The NAS Pensacola Reference Concentration for silver in groundwater is 4 µg/L. The reported concentration is only slightly higher than the Reference Concentration. Although the reported concentration is greater than the ORNL value, due to the low concentration, low frequency of detection, and considering potential dilution upon discharge, silver is considered to pose negligible risk.

Zinc was detected in 12 of 26 samples and 5 of the 12 samples (38GW0501, 38GW1S01, 38GW3S01, 46GW0601, 46GW0701) had concentrations (166 µg/L, 130 µg/L, 115 µg/L, 156 µg/L, and 164 µg/L respectively) in excess of the USEPA Region IV salt water ESV (86 µg/L). All detected concentrations were less than the USEPA Region IV fresh water ESV (343 µg/L) based on a maximum hardness of 400mg/L. The NAS Pensacola Reference Concentration for zinc in groundwater is 153 µg/L. All detected concentrations but two are below this reference value. Based on the comparison to the reference concentration, the limited number of samples that exceeded the USEPA Region IV ESV, and potential dilution upon discharge, zinc is considered to pose negligible risk.

USEPA Region IV salt water ESVs were not available for seven metals (aluminum, barium, beryllium, cobalt, iron, manganese, and vanadium). Alternate sources of screening benchmarks were researched and where available, comparisons to groundwater concentrations were made.

USEPA has published a National Recommended Water Quality Criteria (NRWQC) for aluminum that is based on surface water pH (USEPA, 2006). The chronic fresh water criterion is 87 µg/L for a pH range of 6.5 to 9.0. No salt water criterion is available for aluminum. Aluminum was detected in 8 of 26 samples and all eight samples had concentrations in excess of the NRWQC chronic criterion. No pH data is available for the sampled groundwater. The NAS Pensacola Reference Concentration for aluminum in groundwater is 3,882.76 µg/L. Only 4 of 26 samples had concentrations in excess of the Reference Concentration. Considering the comparison to the reference concentration and dilution upon discharge, potential risk from aluminum is considered minimal.

An ORNL Tier II SCV (Suter and Tsao, 1996) is available for barium (4.0 µg/L). Barium was detected in 24 of 26 groundwater samples exceeding the SCV in all samples. Although barium was detected in the majority of samples at concentrations above the fresh water SCV, based on potential dilution effects upon discharge to Pensacola Bay, potential risk from barium is considered minimal.

An ORNL Tier II SCV (Suter and Tsao, 1996) is available for beryllium (0.66 µg/L). Beryllium was detected in 4 of 26 samples at concentrations less than the fresh water SCV. The NAS Pensacola Reference Concentration for beryllium in groundwater is 1.1 µg/L. All samples had concentrations less than this reference value. Based on the low concentrations, low frequency of detection, and potential effects of dilution, potential risk from beryllium in groundwater is considered negligible.

An ORNL Tier II SCV (Suter and Tsao, 1996) is available for cobalt (23 µg/L). Cobalt was detected in 5 of 26 samples at concentrations less than the fresh water SCV. The NAS Pensacola Reference Concentration for cobalt in groundwater is 4.1 µg/L. All detected concentrations of cobalt in groundwater are less than this reference value. Based on the low concentration, low frequency of detection, and potential effects of dilution, potential risk from cobalt in groundwater is considered negligible.

No salt water screening benchmark was identified for iron but a chronic fresh water NRWQC (1,000 µg/L) was found for comparison to detected groundwater concentrations. Iron was detected in 12 of 26 samples of which 10 samples had an iron concentration in excess of the NRWQC. The screening value for iron of 1,000 mg/L is based primarily on field observation of cold water species. The criteria rationale notes that variations in ambient surface water conditions including alkalinity, hardness, pH, temperature, and the presence of ligands may affect the solubility and ultimately the toxicity of the metal (USEPA, 1976). Although iron was detected in a number of samples at concentrations above the fresh water NRWQC, based on potential dilution effects upon discharge to Pensacola Bay, potential risk from iron is considered minimal.

Manganese was detected in 22 of 26 groundwater samples with no concentrations exceeding the ORNL (Suter and Tsao, 1996) SCV (120 µg/L). Based on this information and potential dilution effects upon discharge to Pensacola Bay, potential risk from manganese is considered negligible.

Vanadium was detected in 10 of 26 groundwater samples and four of these samples had concentration in excess of the ORNL (Suter and Tsao, 1996) SCV (20 µg/L). Although vanadium was detected in samples at concentrations above the fresh water SCV, based on potential dilution effects upon discharge to Pensacola Bay, potential risk from vanadium is considered minimal.

7.7 UNCERTAINTY

Uncertainty is associated with all aspects of the ecological assessment methodology presented in the preceding sections. This section provides a summary of the uncertainties.

7.7.1 Uncertainty in the Problem Formulation

There is uncertainty in the extent that wildlife receptors are present at Site 46. The site provides poor habitat comprised of paved surfaces, buildings, and disturbed soils and as a result, significant habitation and foraging probably does not occur at the site. The precise extent of overestimation is uncertain.

7.7.2 Uncertainty in the Ecological Effects Characterization

The ESVs used in the assessment might not adequately represent toxicity thresholds for receptors under field conditions. In addition, the ESVs might not adequately represent toxicity thresholds for other species. These uncertainties may overestimate or underestimate potential risks.

Data for investigating toxicity to reptiles and amphibians from oral ingestion of contaminants are sparse. Thus, potential risks were not evaluated for reptiles and amphibians. Due to the lack of habitats for reptiles and amphibians at the site, the resulting uncertainty is minor.

7.7.3 Uncertainty in the Exposure Assessment

Detection limits for some non-detected metals (nickel and silver) in groundwater exceeded ESVs in some samples (Table 7-2). While the high detection limits prevents a complete evaluation of the presence of these metals in these samples, the overall impact of this uncertainty is not considered significant.
The dermal exposure for upper-level receptors was not evaluated, potentially underestimating risks. However, because few upper-level receptors probably use Site 46, this exposure route is considered negligible.

Soil samples evaluated in this risk assessment consisted of samples no deeper than 1 foot below the soil surface. However, tree roots extend deeper than 1 foot below the surface, and mammals such as moles could burrow deeper than 1 foot. With the exception trees, terrestrial species at the site would rarely (if ever) be exposed to soils deeper than 1 foot below the surface. The uncertainty resulting in evaluating only surface soils is negligible.

7.7.4 Uncertainty in the Risk Characterization

This uncertainty results from the combination of the above uncertainties. A weight-of-evidence approach to assess risks was used to reduce the overall uncertainty in these situations.

Uncertainty in risk characterization also results from the lack of data regarding the toxicity of multiple chemicals. For example, detectable concentrations of multiple COPCs were identified at several locations. The extent to which these concentrations might contribute to cumulative toxicity is uncertain.

7.8 SUMMARY AND CONCLUSIONS

Concentrations of a number of contaminants in surface soil exceeded conservative screening levels that are associated with potential risk to ecological receptors. Several detected contaminants, while possibly associated with Site 46, may also have been transported from adjacent IR Site 38 through the trenches that connected the former buildings, and via storm water runoff. Similarly, contaminants detected in groundwater may be associated with Site 46 or upgradient source(s) such as IR Site 38. When conservative assumptions used in the ecological risk assessment are re-evaluated and factors that affect potential exposures such as quality of the habitat and potential use of the site by ecological receptors are considered, the overall level of ecological risk associated with detected contaminants is considered to be minimal. The following conclusions are discussed by the groups of chemical contaminants identified at Site 46.

While overall risk to soil invertebrates and plants from VOC contaminants at Site 46 is low, the results indicate potential risk to plants and soil invertebrates from TCE, particularly in the area of sample 46SB2901. However, this risk is lessened by the limited area of exposed soil available to soil invertebrates and plants.

There is uncertainty regarding potential risk associated with VOCs in groundwater for which no ESVs are available however, the low VOC concentrations should become even more dilute upon discharge to Pensacola Bay and are not expected to be associated with unacceptable risk.

There is uncertainty regarding potential risk associated with PAHs for which no surface soil ESVs are available; however, total PAH concentrations were less than the USEPA Region IV ESV and the other cited benchmarks. Thus, risks to plants and soil invertebrates from PAHs are negligible.

Potential risk from PAHs in groundwater is considered negligible.

Potential risk from bis(2-ethylhexyl)phthalate detected in groundwater is considered negligible.

Pesticides were not detected in surface soil at Site 46 and were detected in groundwater at low frequency and low concentrations. Considering the low frequency of detection and dilution upon discharge in Pensacola Bay, potential risk from chlorinated pesticides is considered negligible.

Based on the detected concentration of Aroclor-1260, its frequency of detection, and the comparison to benchmarks, potential risk from PCBs in surface soil at Site 46 is considered minimal.

Overall, potential risk to plants and soil invertebrates from metals in surface soil appears negligible, but a low level of potential risk to plants may be present from lead in surface soil. However, this risk is lessened by the limited areas of exposed soil available to soil invertebrates and plants. While no pH data is available for surface soil at Site 46, potential risk to plants and soil invertebrates from aluminum and iron is considered negligible.

Potential risk from metals detected in groundwater at Site 46 is considered negligible.

8.0 SUMMARY AND CONCLUSIONS

The primary objective of this RI is to provide data to evaluate the current environmental conditions and guide the selection of a remedy that is protective of human health and the environment for any contamination present at Site 46. In order to achieve this primary objective, samples from various media were collected and analyzed to fill data gaps from previous investigations. Samples from various media were used to evaluate the extent of contamination previously documented at the site and current site conditions.

8.1 SITE HYDROLOGY

The depth to groundwater at Site 46 ranges from 3 to 5 feet in the shallow monitoring wells and from 4 to 5 feet in the deep monitoring wells and is controlled primarily by surface topography and proximity to Pensacola Bay. Groundwater flow direction in the shallow groundwater interval is to the south towards Pensacola Bay. The estimated average groundwater velocity for the shallow zone at the site was calculated at 2.86 feet/day and the estimated average groundwater velocity for the deep zone at the site was calculated at 0.19 feet/day. Vertical gradients were observed in adjacent pairs of shallow and deep monitoring wells, with upward gradients to the north of Radford Boulevard and adjacent to Pensacola Bay.

8.2 SOIL ASSESSMENT

The release of contaminants at Site 46 probably resulted from routine aircraft maintenance activities and storage of materials used in these activities. The detection of metals and CVOCs at Site 46 supports paint stripping activities as a probable source of contamination.

The lead screening identifed one surface soil sample location with a lead concentration greater than the residential SCTL, but less than the industrial SCTL (Figure 8-1). Reported lead concentrations in all soil samples collected from below 6 inches were less than the residential SCTL. The lead concentration in the site characterization sample collected from the same interval in an adjacent soil boring was less than the residential SCTL, suggesting that lead contamination is limited in site soil. Lead concentrations in soil samples submitted for SPLP extraction did exceed the GCTL for lead.

Arsenic was reported at concentrations equal to or greater than the residential SCTL in the soil samples collected from 0-6 inches and 6 inches to 2 feet at one soil boring location (Figure 8-1). However, the detected concentrations were within the background range determined by the facility-wide statistical evaluation analysis of arsenic and iron for NAS Pensacola (Appendix B), and are therefore not believed

to represent a release of arsenic due to site activities. These samples were collected from a soil boring adjacent to the area investigated for IR Site 38.

Aluminum was reported in one soil characterization sample with a SPLP result greater than the NAS Pensacola reference concentration. Aluminum was detected in the SPLP results for seven other samples at concentrations greater than the GCTL, but less than the NAS Pensacola reference concentration.

TCE was detected at two soil boring locations near the northeast corner of Building 72 at concentrations greater than the industrial SCTL and leaching SCTL (Figure 8-1). Two additional locations had TCE concentrations exceeding the leaching SCTL.

Chloromethane, methylene chloride, PCE , and cis-1,2 DCE were detected in soil screening samples at concentraions greater than the Leaching SCTLs. Acetone and phenol were also detected at concentrations exceeding the leaching SCTL in one confrirmation soil sample from the same area as the TCE exceedances.

8.3 GROUNDWATER ASSESSMENT

Groundwater samples collected at Site 46 were analyzed for the full suite of TCL and TAL analytes and petroleum hydrocarbons. Concentrations of pesticides, PCBs and TRPH in groundwater were less than the laboratory detection limits. These laboratory detection limits were less than the GCTLs or the target practical quanititation limits (FDEP, 2004b), where established.

VOCs, SVOCs, and PAHs were reported in groundwater samples collected at Site 46. TCE and vinyl chloride were the only VOCs detected at concentrations exceeding GCTLs in multiple wells. Previously installed Site 38 monitoring wells 38GS03 (11 μg/L) and 38GS13 (17 μg/L) were reported to contain the elevated concentrations (Figure 8-2). The vinyl chloride concentrations also were greater than the marine surface water criteria of 2.4 μg/L. Bromodichloromethane (PEN-46-01) and chlorodibromomethane (PEN-46-14) were each detected in one groundwater sample at concentrations slightly exceeding the GCTLs. Naphthalene was detected in four of the groundwater samples collected at Site 46, with the concentration in one monitoring well greater than the GCTL. Bis(2-ethylhexyl)phthalate was detected at a concentration greater than the GCTL in one field duplicate sample. The well was resampled in May 2006 and the bis(2-ethylhexyl)phthalate result from that sampling event was less than the laboratory detection limit. Concentrations of pesticides, PCBs and TRPH were less than the laboratory detection limits.

A wide range of metals were reported in groundwater samples collected at Site 46. Arsenic (PEN-46-19), cadmium (38GS05), and lead (38GS01) were each detected in one shallow monitoring well at

concentrations greater than their GCTLs. An exceedance of the chromium GCTL was detected in one deep monitoring (PEN-46-16).

Manganese was detected in most of the groundwater samples collected at Site 46. The reported manganese concentrations in nine monitoring wells exceeded the manganese GCTL. These exceedances occurred equally in monitoring wells screened in the shallow and the deep surficial aquifer.

Sodium was detected in most of the groundwater samples collected at Site 46. The reported sodium concentrations in 18 monitoring wells exceeded the sodium GCTL. These exceedances occurred equally in monitoring wells screened in the shallow and the deep surficial aquifer.

Aluminum, iron and vanadium were detected in only deep monitoring wells at concentrations exceeding the screening criteria.

Analytical results from selected monitoring wells located closest to Pensacola Bay were also compared to the GCTLs for discharge to marine surface waters. Vinyl chloride concentrations in two wells (PEN-38GS03 and PEN38GS13) exceeded the marine surface water criteria as well as the GCTL. These monitoring wells are previously installed wells from the Site 38 RI that were sampled for the Site 46 investigation. The naphthalene concentration in one well, PEN-46-19, exceeded the marine surface water criteria as well as the GCTL.

Iron concentrations in two wells, PEN-46-14 and PEN46-20, exceeded the marine surface water criteria as well as the GCTL.

Beyrillium (PEN-46-20), chromium (PEN-38GI03), copper (PEN-46-20), nickel (PEN-46-14), and zinc (38GS03), were detected in at concentrations greater than the marine surface water criteria but less than the NAS Pensacola reference concentrations or GCTLs.

8.4 HUMAN HEALTH RISK ASSESSMENT

The risk assessment considered five receptor scenarios; however, maintenance workers and trespassers/recreational users are considered to be the most likely receptors at Site 46 under current land use. The carcinogenic and non-carcinogenic risks for the hypothetical future resident exceed USEPA and FDEP target risk levels and HIs, respectively, for soil and groundwater. In soil, the primary driver of risk is TCE; in groundwater, the primary drivers of risk are chlorinated VOCs and arsenic. For the construction worker, concentrations of aluminum in surface soil elevate the HI above the target of 1. For the industrial worker, concentrations of TCE in surface and subsurface soil elevate the ILCR above

1×10^{-6}. Concentrations of lead in soil and groundwater do not result in blood level lead concentrations in any of the evaluated receptors.

8.5 ECOLOGICAL RISK ASSESSMENT

The ecological risk assessment evaluated factors that affect potential exposures such as quality of the habitat, and potential use of the site by ecological receptors. The overall level of ecological risk associated with detected contaminants is considered to be minimal. Potential risk to soil invertebrates and plants from TCE and lead at Site 46 is low. This risk is lessened by the limited area of exposed soil available to soil invertebrates and plants.

8.6 CONCLUSIONS

The area at the northeast corner of Building 72 (Figure 8-1) is the location where TCE and other CVOCs were detected in surface soil and subsurface soil samples at concentrations exceeding risk-based screening criteria. The elevated human health risk will require active remediation to prevent further impact to site groundwater. An interim removal action should be considered to expedite site cleanup in this area.

Metals and CVOCs in groundwater at Site 46 exceeded risk-based screening criteria. The proposed plan for remediation at Site 38 has established that natural attenuation of metals and CVOCs is sufficently protective of human health and the environment. Because the groundwater contaminants and concentrations for Site 46 are similar to those of Site 38, a similar remedial approach, monitored natural attenuation, should be considered for Site 46. A detailed evaluation of alternatives to achieve this goal should be presented in a Feasibility Study for Site 46.

Type of Surface Seal: Flush Mount finish

I.D. of Riser: 2-inch

Type of Riser: Sch 40 PVC

Borehole Diameter: 8-inch to 25', then 4-inch

Elevation / Depth Top of Rock: NA/

Type of Backfill: Portland grout

Elevation / Depth of Seal: / NA

Type of Seal:

Elevation / Depth of Top of Filter Pack: / 33.0

Elevation / Depth of Top of Screen: / 36.0

Type of Screen: Sch 40 PVC

Slot Size x Length: .01-inch 10 ft

I.D. of Screen: 2-inch

Type of Filter Pack: 20/30 sand

Elevation / Depth of Bottom of Screen: / 46.0

Elevation / Depth of Bottom of Filter Pack: / 46.0

Type of Backfill Below Well: Formation collapse (sand)

Elevation / Total Depth of Borehole: / 49.0

Compiled by U.S. Fish and Wildlife Service, October, 2003

Common Name	Scientific Name	Status State	Status FWS	Natural Communities
Narrow pigtoe	*Fusconaia escambia*		C (E)	Riverine: small to medium-sized creeks and rivers with slow to moderate current over gravel, and gravel mixed with sand or some silt. Endemic to the Escambia and Yellow River drainages of Alabama and Florida
Round ebonyshell	*Fusconaia rotulata*		C (E)	Riverine: Endemic and restricted to the main channel of the Conecuh River AL, and Escambia River, FL
Fuzzy pigtoe	*Pleurobema strodeanum*		C (E)	Riverine: small to medium-sized creeks and rivers with slow to moderate currents in sand and sand with some silt. Endemic to the Escambia, Yellow, and Choctawhatchee River drainages of Alabama and Florida.
Choctaw bean	*Villosa choctawensis*		C (E)	Riverine: Small to large creeks and rivers with moderate current over sand to silty-sand substrates. Endemic to the Escambia, Yellow, and Choctawhatchee River drainages of Alabama and Florida.
Downy rainbow (mussel)	*Villosa villosa*		ce	RIVERINE: small streams to large rivers in sand or muddy sand substrates (Panhandle watersheds: Apalachicola, Chipola, Escambia, Choctawhatchee, Ochlockonee, Suwannee)
PLANTS:				
Sweet shrub	*Calycanthus floridus*	E		TERRESTRIAL: upland hardwood forest, slope forest, bluffs PALUSTRINE: bottomland forest, stream banks, floodplains
Baltzell's sedge	*Carex baltzellii*	T	ce	TERRESTRIAL: slope forest, moist sandy loam; moist sandy loam
Godfrey's golden aster	*Chrysopsis godfreyi*		ce	TERRESTRIAL: beach dunes, coastal grassland
Cruise's golden-aster	*Chrysopsis gossypina cruiseana*	E	ce	TERRESTRIAL: coastal dunes, coastal strand, coastal grassland; openings and blowouts
Spoon-leaved sundew	*Drosera intermedia*	T		LACUSTRINE: sinkhole lake edges PALUSTRINE: seepage slope, wet flatwoods, depression marsh RIVERINE: seepage stream banks, drainage ditches
Trailing arbutus	*Epigaea repens*	E		TERRESTRIAL: bluff, slope forest, mixed hardwood forest
Heartleaf	*Hexastylis arifolia*	T		RIVERINE: seepage stream bank TERRESTRIAL: slope forest
Florida anise	*Illicium floridanum*	T		PALUSTRINE: floodplain forest, baygall RIVERINE: seepage stream bank TERRESTRIAL: slope forest, seepage slope
Mountain laurel	*Kalmia latifolia*	T		RIVERINE: seepage stream bank TERRESTRIAL: slope forest, seepage stream banks
Bog-button	*Lachnocaulon digynum*		ce	PALUSTRINE: seepage slope, wet flatwoods, bog TERRESTRIAL: seepage slopes, wet flatwoods; exposed sands
Southern red lily	*Lilium catesbaei*	T		PALUSTRINE: wet prairie, wet flatwoods, seepage slope TERRESTRIAL: mesic flatwoods, seepage slope; usually with grasses
Panhandle lily	*Lilium iridollae*	E	ce	PALUSTRINE: baygall, dome swamp edges, mucky soil, seepage slope, edges of titi bogs, RIVERINE: blackwater stream banks

E=endangered, T=threatened, P=proposed, C=candidate,s/a=Similarity of appearance, SSC=Species of Special Concern,ce=Consideration encouraged,CH=Critical habitat

Use of Geochemical Analysis in Identification of Inorganic Contamination in Soil
Naval Air Station Pensacola (NASP), Pensacola, Florida

Introduction:

This technical brief has been prepared to present a geochemical methodology that can be simply applied to site-specific data to identify "outliers" for a given inorganic (those samples that fall outside of expected natural concentrations) at NASP. Inherent to this is the use of the methodology to define the naturally occurring range of the inorganic. In this document, using the available data from base-wide investigations, the geochemical method of identifying the range of naturally-occurring inorganics has been used for arsenic in soil at NASP, and the consequent model can be applied to determine if site samples contain arsenic outside of the naturally occurring range. The geochemical method is relatively new (US Navy, 1999; US Navy, 2002; Gannett Fleming 2005; Caldwell, et. al, 2005a&2005b), but is based on robust statistical methods and has been used successfully to define inorganic outliers (Caldwell, et al 2005a, Gannett Fleming 2005). A significant programmatic approach utilizing this method has been performed at Avon Park Air Force Range (APAFR; Gannett Fleming 2005), and similar statistical procedures have been followed for NASP. Because the work performed at Avon Park has been extensively reviewed and accepted by both Florida Department of Environmental Protection (FDEP) and the EPA, relevant language is either paraphrased or excerpted in this technical brief.

Data Source:

In 1992 a small set of approximately 20 soil samples were collected from known un-impacted areas to represent "background" for NASP. Since then, numerous site investigations have been performed, yielding a soil dataset on the order of 2000 soil samples. In a recent guidance document (USEPA, 2002) "background" is defined according to whether substances of interest are:

- *Naturally occurring*: substances present in the environment in forms that have not been influenced by human activity, or
- *Anthropogenic*: natural and man-made substances that are present in the environment as a result of human activity but are not specifically site-related

A background population, ideally, is a collection of samples that represents ambient conditions, i.e., not influenced by site-related human activities, at a location of interest.

Included in the EPA definition of background are anthropogenic contributions that are not related to activities at a particular site. Three possible means of identifying a population of background samples are:

1. *From site investigations.* At many Federal facilities and elsewhere, large numbers of samples have been collected as part of routine site investigations, giving rise to the possibility that the "background" geochemical signal may be extracted from facility-wide data sets. Ideally, a background data set obtained in this manner would be desirable because the samples of which it is comprised would be truly representative of the same soil types as the site soils. By using facility-wide data as the basis for identifying the background geochemical signature,

the distribution of background samples is spatially constrained and so differences between "background" and "site" data attributable to large-scale, non-point-source effects (e.g., aerial deposition, regional differences in geologic environment, etc.) are minimized. However, this approach necessarily means that some subset of the facility-wide data consists of soil with chemical compositions reflecting naturally occurring and/or anthropogenic background conditions, and some other subset contains samples bearing site-related contamination.

2. *From basewide sampling.* Many Federal facilities have conducted investigations specifically for the purpose of establishing facility-wide background concentration ranges. Typically, such studies sample locations that are agreed upon as "clean" but are from geologically, hydrologically, and geochemically similar environments as the site samples. In principle, this approach is well motivated, but in practice, the background samples may not be representative of site soils. Another limitation often encountered in examining data collected specifically to establish basewide background is the size of the sample population. In many cases, it is not clear that a sample set of the order of n = 20 is representative of the full range of background conditions.

3. *From other, independently derived data sets.* Other data sets have been assembled by state agencies, the US Geological Survey, and other entities, for independent purposes. Examples are the background concentrations established for Florida soils from a statewide investigation (Table 3; Chen et al., 1998, 1999), or the nationwide data set assembled by the US Geological Survey (Table 4; Boerngen and Shacklette, 1981). The data from both sets are similar in concentration ranges for all of the elements of interest.

At NASP, there is only one site that is known to be directly associated with arsenic as an integral part of site activities (Site 15 Pesticide Rinsate Disposal Area; associated with arsenate-containing pesticides). Because of the limited number of samples collected at this site relative to the cumulative number collected from site investigations, the entire dataset from all site investigations including Site 15 was used as the basis for determining the natural occurrence of arsenic in soil at NASP.

Choice of Background Modeling Methods:

Two generally accepted methods for determining the natural occurrence of inorganic analytes using pre-existing data are population modeling and geochemical modeling (US Navy 2002; EPA 2000). The successful use of population modeling depends on the distribution of the data (normal or log-normal) and a reasonable ratio of detected analytes to non-detected analytes (NDs). If the data are neither normal nor log-normally distributed (meaning they are naturally skewed on either the low or high end), the ability to predict their natural distribution and identify outliers is compromised. Similarly, the incorporation of non-detects into the modeling requires that the NDs comprise no more than 15% of the data; when they are greater than 15% reasonable conclusions regarding the data distribution cannot be made (US Navy, 2002; EPA 2000).

The Facility-wide soil dataset at NASP (included electronically as Attachment A) contains 2,106 samples analyzed for arsenic. Of these, only 751 or 37.25% had detectable arsenic concentrations (ranging from 0.1-66.3 mg/kg) and 1,265 or 62.75% were non-detect. Because the number of samples with no detection of arsenic was significantly greater than 15%, population modeling

was not performed to determine the naturally occurring range of arsenic. Instead, modeling using the geochemical method was preformed (US Navy, 2002; Caldwell, et. al, 2005a; Gannett Fleming 2005).

Geochemical Modeling:
The concept of a 'geochemical evaluation' uses knowledge of naturally occurring geochemical processes to discriminate between concentrations of inorganic elements (specifically trace metals) that are characteristic of ambient soil/groundwater conditions, and levels that are likely to have resulted from site activities. In soils, trace metal abundances are often controlled by processes that take place during soil formation. The elements of interest are liberated from their sources – for example, in minerals present in bedrock – by a number of mechanical, chemical, and microbial processes that occur during and after erosion, transport, and re-precipitation. Trace metals are often present in soils in constant proportions to a reference element (e.g., iron, aluminum, manganese, etc.) due to the integrated effects of any of a number of geochemical processes. These include adsorption onto oxides, hydroxides, and oxyhydroxides of iron, aluminum, and manganese; uptake by other surface complexation mechanisms; coprecipitation through substitution for elements with similar electrical charge and ionic radius; sorption onto clay mineral surfaces; and complexation by soil organic material. These processes are often geographically widespread and result in distributions of trace metals in fixed proportion to one another and to microelements such as iron, aluminum, or manganese.

The geochemical evaluation focuses primarily on graphical presentation of the data so that relationships between a "reference element" (e.g., iron, aluminum, or manganese) and other, trace metals, can be visually compared. When the log-transformed concentration of a trace metal of interest (for example, arsenic) is plotted against a reference element (for example, iron), the data often plot along a trend that is described by a straight line. A linear correlation indicates that these pairs of elements are present in a constant proportion as defined by the regression equation, which represents the *integrated* effects of naturally occurring geochemical processes: often, these ratios are approximately constant regardless of soil type, soil horizon, geological environment, or geographic location. Superimposing the regression line and the 95% upper and lower prediction limits *derived from the background data* on a site data set permits rapid visual assessment of any outliers. Conversely, data from many sites frequently lie within the 95% prediction interval and so may be considered to be consistent with the background population. Alternative methods for evaluating the linear correlation is to sequentially remove data points based on their iterative decrease in magnitude of their variance from a trend line until a desired correlation is met or until data removal does not result in an increase in correlation; the removed data are then considered outliers and the remaining are considered representative of natural conditions (Caldwell, 2005A, 2005b). This method also provides a range of ratios between the dependent and independent variable that can be used to bound the natural conditions. Thus, even though individual samples may report elevated concentrations of constituents of potential concern (e.g., arsenic) when compared to a singular screening criteria (e.g., soil screening level) based on arsenic *alone*, these levels may be naturally occurring nevertheless and do not necessarily reflect site impact. Conversely, significant deviations from a linear correlation – for example, due to enrichment of an element above a generally linear trend – may indicate contamination.

Modeling Technique:

The technique to model the geochemical relationship is the use of linear regression. Linear regression is a bivariate statistical solution that quantifies the relationship between two variables, one dependent and the other independent (unknown variable and a predictor variable). Use of this technique in the environmental arena assumes that, between two geochemically similar inorganics, they will co-exist at a relatively constant relationship under natural conditions, including variations in soil types and environmental conditions. Variations from this relationship signify a deviation from natural conditions, and therefore can be used as an indicator of potential contamination. Geochemically similar inorganics are chosen to be paired for the linear regression, as it is likely that intrinsic environmental conditions act on both of them equally (for example iron and arsenic or aluminum and lead). For this evaluation, iron was used as the independent variable and arsenic the dependent. In the geochemical method, no non-detects are used. Of the 2016 samples analyzed for arsenic, 1851 were also analyzed for iron. Of these 1851 samples, 653 had detections of both iron and arsenic; these samples were used in the geochemical evaluation.

The mechanical process of using linear regression in environmental data involves plotting of the paired values (from the same sample) of both the dependent and independent inorganics on both normally-scaled and log-scaled axes (or log-transformed data on linear –scaled axes). The resulting statistic that quantifies the degree to which the two inorganics are correlated is the correlation coefficient R (also referred to as Pearson's product moment coefficient); this statistic ranges from 1.0 to -1.0, with the sign designating either a positive or negative correlation, and the numerical value designating the magnitude of correlation (1.0 or -1.0 representing a perfect 1-to-1 relationship). The process consists of plotting the paired data and calculating the R value; the best correlation between the two variables is then represented graphically by the linear equation:

$$y = mx+b$$

where m = the rate of change in the variables relative to each other, and
b is the intercept on the y-axis.

On the graph, the line used to calculate the regression equation is fit through all of the data using a least-squares fit, whereby the variance from the line for each point (in total) is minimized. Once the data is plotted, the square of the correlation coefficient (the coefficient of determination - R^2) is used to quantify the proportion of variance in each variable that is explained by its co-occurrence with the other. For positive correlations that are normally encountered with environmental inorganic analytes (more of one constituent results in more of the other), an R^2 value of 0.6 (60 % explained variance, correlation coefficient of 0.77) is considered significantly correlated, 0.8 (80 % explained variance, correlation coefficient of 0.89) is considered strongly correlated and 0.9 (90% explained variance, correlation coefficient of 0.95) is considered very strongly correlated. Linear regressions can be performed for both non-transformed and log-transformed data. In the case where variances are relatively small, non-transformed data plots tend to illuminate deviations from the least-squares trend line better than log-transformed data, which minimizes the magnitude of variances from the trend line and between points.

For NASP, the entire dataset from site investigations was used to perform linear regressions to define natural conditions. As a result, it was recognized that some samples representing potentially contaminated conditions would be included in the dataset. To identify those samples, and to arrive at a dataset that is representative of natural conditions, a process of sequential elimination was employed (Caldwell et. al, 2005a, 2005b). In this process, the raw data for paired inorganics are plotted and a consequent least-squares trend line is calculated and plotted. Data are then sequentially removed from the dataset based on the magnitude of their variance from the trend line (larger magnitudes are removed before those with less). Once a data point is removed, the R^2 value is re-calculated. This is continued on an iterative basis (virtual remediation) until the R^2 value is 0.6 or greater (or until a point is reached at which the R^2 value does not increase with outlier removal), indicating that significant correlation exists between the remaining data (Caldwell, et. al 2005a). It is critical that the process of data removal is objective, namely that using the magnitude of variance from the least-squares trend line is the criteria for data removal.

Arsenic Geochemical Model Results:

The geochemical modeling data is presented in logical steps, including:

a) All raw non-transformed data plotted with a least-squares trend line;
b) Non-transformed data plotted with a least-squares trend line and outliers removed;
c) All transformed data plotted with a least-squares trend line;
d) Transformed data plotted with a least-squares trend line and non-transformed identified outliers removed;
e) Transformed data with a least-squares trend line and outliers removed.

The following graphs and tables present the above – cited data.

Figure 1. Arsenic and Iron – Raw Data

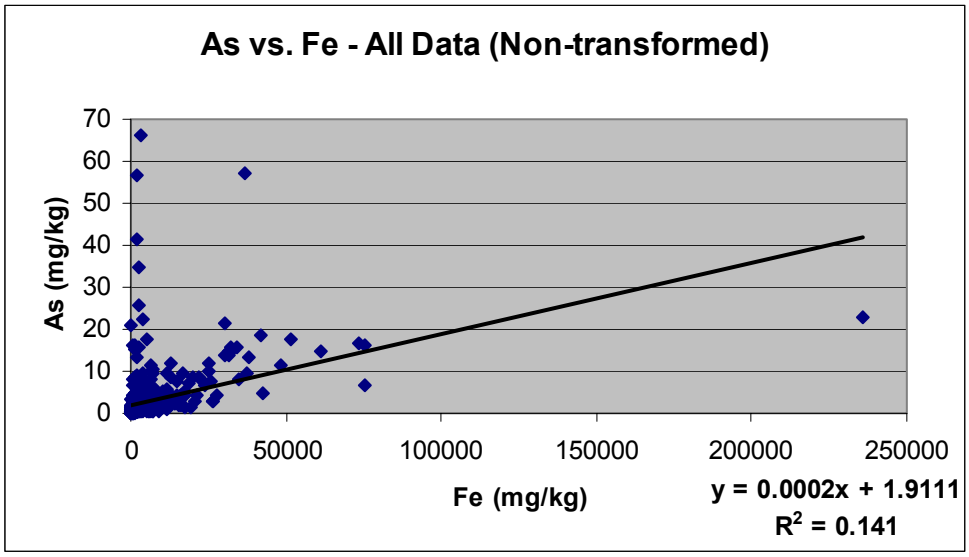

Figure 2. Arsenic and Iron – Outliers Removed; Non-transformed data

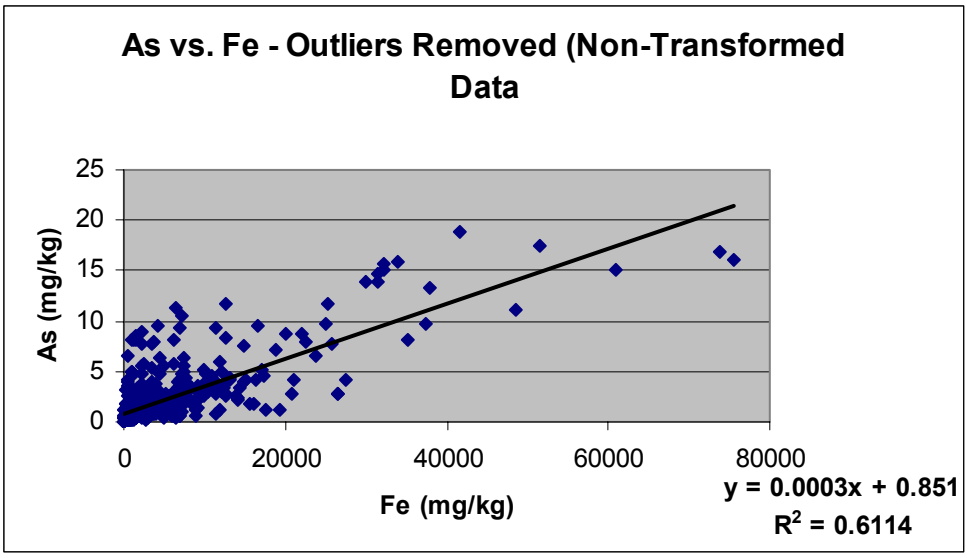

This graph presents the plot of non-transformed data with outliers removed. The outliers data were sequentially removed until an R^2 value of 0.6 or better with the remaining data was arrived at. Table 1 presents the outliers in the order in which they were identified and removed.

Table 1. Outliers Removed – Non-transformed data

Site	Sample	Parameter	Value (mg/kg)	Parameter	Value (mg/kg)	Enriched Inorganic

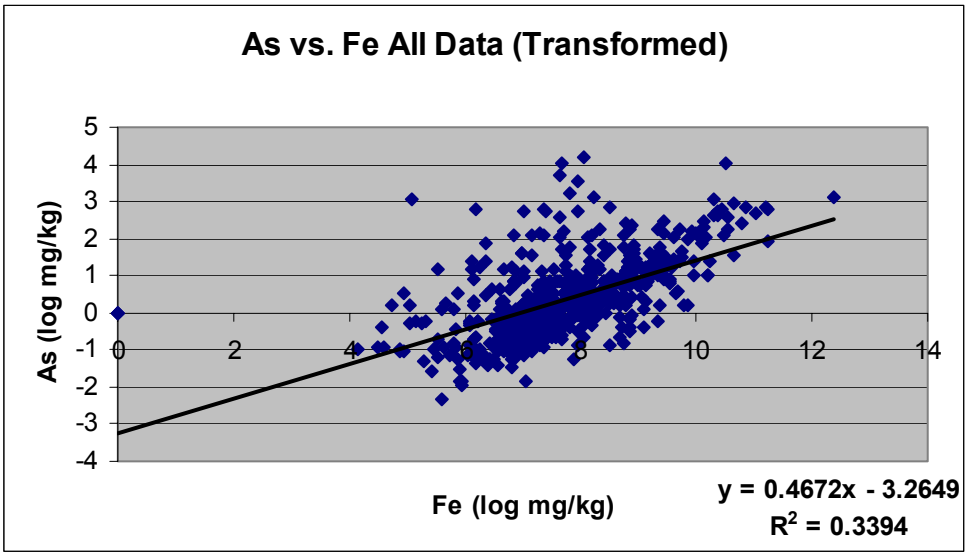
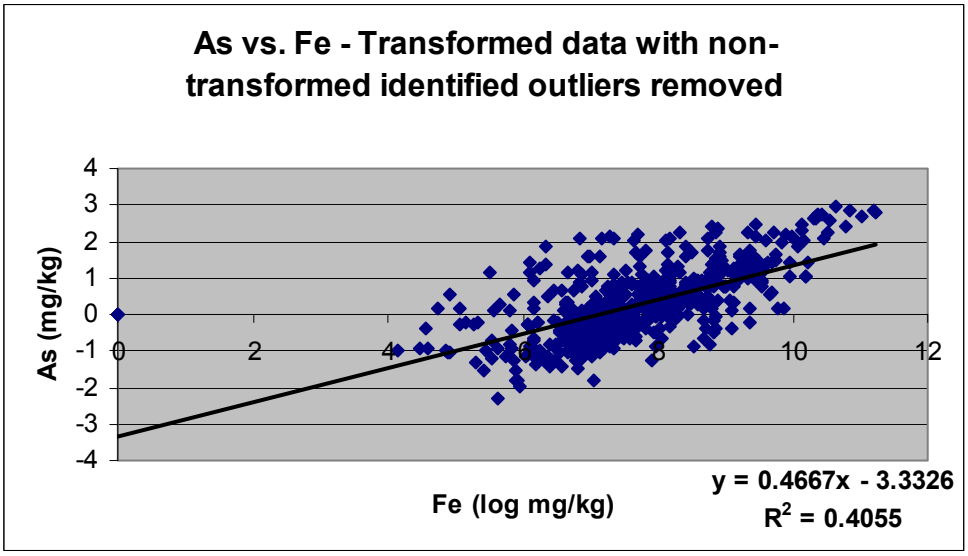
Figure 3. Arsenic and Iron; All data - Transformed



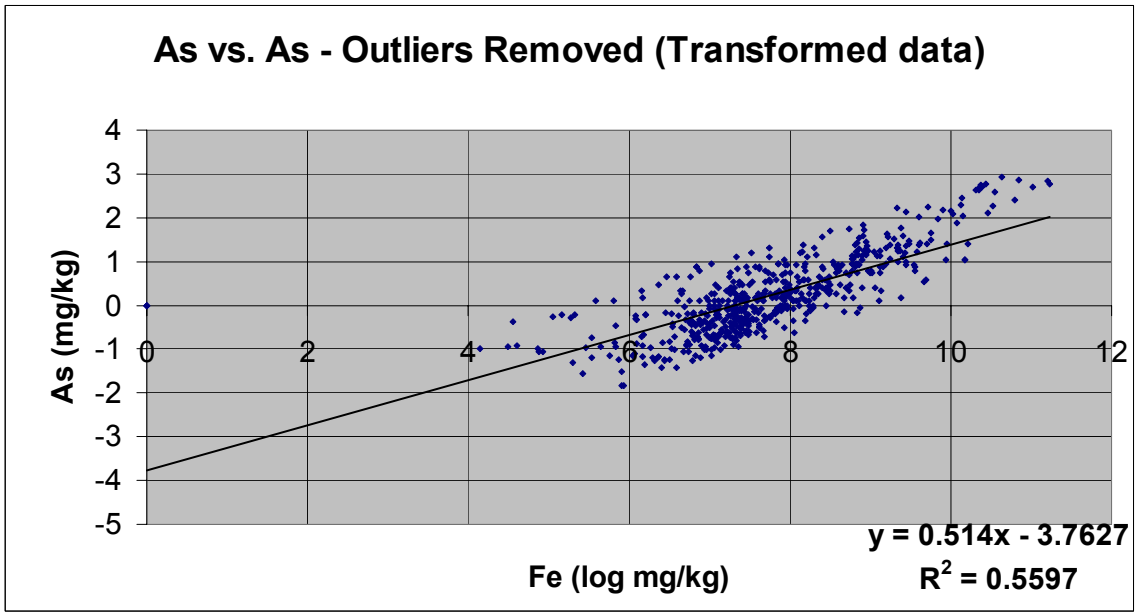
This graph presents the entire dataset plotted after log-transformation.

Figure 4. Arsenic and Iron- All data; Non-transformed identified outliers removed



This graph represents the beginning point for the transformed data analysis; all sequential removal of outliers proceeded using this dataset as the starting base. Identical to the non-transformed data, outliers were iteratively identified and removed based on their variance from the least-squares regression trend line. In the case of the transformed data, outliers (identified by their magnitude of variance from the least-squares trend line) were removed until which time additional point removal caused the R^2 value to decrease (0.5814), a threshold point at which the maximum natural correlation was reached.

Figure 5. Arsenic and Iron – Non-Transformed and Transformed data outliers removed



In sequential removal of outliers in the transformed data, the graph above represents the limit of sample points that could be removed objectively (using magnitude of variance from the least – squares trend line as the criteria) with a consequent increase in the R^2 value. Removal of additional outliers above the R^2 value of 0.5597 began to result in lower R^2 values. Although it is possible the R^2 value could be further increased, it could be considered subjective as the variance between points was increasingly similar and it would not be based on sequentially removing points with the highest variance from the trend line. As a result, the regression above (55.97% explained variance) effectively represents the upper limit of correlation between As and Fe that naturally occurs at NASP. Because of the dulling effect of log transformation (which decreases the difference in magnitude of variance between points and results in smaller changes in R^2 value when one is removed), more outliers were identified in the transformed regression. These outliers are listed in order of their removal from the dataset in Table 2.

Conclusions:

Based on the method of geochemical regression modeling (US Navy 2002; Gannett Fleming 2005), the soil data from all NASP investigations were evaluated for arsenic. The dataset consisted of a total of 2,668 soil samples. Of these, 2016 were analyzed for arsenic and 751 had detectable concentrations. Because of the high percentage of non-detects (62.75 %), geochemical modeling was performed over population modeling to define the natural occurrence of arsenic.

Geochemical modeling of arsenic was performed through linear regression against iron, a geochemically similar constituent. There were a total of 651 samples that had detected concentrations of both iron and arsenic that were used in the evaluation. The R^2 value of the raw untransformed data was 0.141; sequential removal of 19 outliers based on their variance from a least squares trend line yielded an R^2 value of 0.6114 (for this evaluation an R^2 value of 0.6 was considered a significant correlation). The R^2 value of the raw transformed data was 0.3394; when the 19 outliers identified during the non-transformed analysis were removed the R^2 value increased to 0.4055. Sequential removal of an additional 54 outliers from the transformed data based on their decreasing variance from the least squares trend line yielded a R^2 value of 0.5597. At this point removal of additional points with the greater variance from the least squares trend line did not result in a consequent sequential increase in the R^2 value, thus the resulting dataset represents the maximum objective correlation between arsenic and iron, which in this case in interpreted to be inferably natural. The final dataset had the following characteristics:

Fe range: 63.4 – 75,600 mg/kg
As range: 0.1 – 17.5 mg/kg
As/Fe ratio range: 0.000101695 to 00071204
Correlation prediction equation (log transformed): y (Fe) = 0.514x (As) – 3.7267

The samples identified as outliers represent statistically significant deviations from the natural distributions for both Fe and As. The geochemical analysis a) identified a total of 73 samples as being statistically different from background conditions (55 enriched with respect to As, and 18 enriched with respect to Fe); and b) provided a prediction equation and a bounding range of ratios of As/Fe that can be used for future sampling to identify samples that are not consistent with background. An additional method that can be used is to bound this geochemical model with the 95% prediction limits; outliers falling outside of this 95% envelope should then be considered outliers (Gannett Fleming, 2005)..

46GW1501	46GW1601	46RB1217	46TB1217

OVERVIEW

The sample set for CTO 367 NAS Pensacola, SDG CTO367-4 consists of two (2) rinse blanks, one (1) trip blank, and seventeen (17) environmental water samples. All samples were analyzed for Target Compound List (TCL) volatile (VOC), semivolatile (SVOC), pesticide (PEST), and polychlorinated biphenyl (PCB) organic compounds; polynuclear aromatic hydrocarbons (PAHs); 1,2-Dibromoethane (EDB), and Total Petroleum Hydrocarbons (TPH). One (1) field duplicate pair was included with this SDG: 46GW1401 / 46GW1401D.

The samples were collected by TetraTech NUS on December 14, 16, 17, 18, and 20, 2005 and analyzed by Katahdin Analytical Services. All analyses were conducted in accordance with SW-846 Methods 8260B, 8270C, 8081A, 8082, 8270C SIM, EPA 504.1, and FL-PRO analysis and reporting protocols.

The data contained in this SDG were validated with regard to the following parameters:

*	• Data completeness
	• Holding times
*	• GC/MS Tuning
	• Initial and continuing calibration
	• Blank results
	• Surrogate spike recoveries
*	• Internal standard recoveries
	• Blank Spike/Blank Spike Duplicate Results
*	• Field Duplicate Results
*	• Detection Limits
*	• Compound Quantitation
*	• Compound Identification

The symbol (*) indicates that quality control criteria were met for this parameter. Problems affecting data quality are discussed below; documentation supporting these findings is presented in Appendix C. Qualified Analytical results are presented in Appendix A. Results as reported by the laboratory are presented in Appendix B.

Volatiles

Chloromethane and toluene were detected in the rinsate blank but environmental samples were not qualified based on rinsate blank contamination.

All initial calibration and continuing calibration relative response factors (RRFs) were less than the 0.05 quality control limit for acetone and 2-butanone on instruments GCMS-S, GCMS-F, and GCMS-M. Positive acetone results were qualified as estimated (J). The nondetected acetone and 2-butanone results were considered unusable and were qualified rejected, (UR). All samples in the SDG are affected.

The continuing calibration run on 12/28/05 at 08:35 on instrument GCMS-S yielded a Percent Difference (%D) for chloromethane that were greater than the 25% quality control limit. The nondetected results reported for this compound were qualified as estimated (UJ) in samples 46TB1217, 46GW1101, 46GW0901, and 46GW1301. The positive result reported for chloromethane in sample 46RB1217 was qualified as estimated (J).

The continuing calibration run on 12/29/05 at 09:07 on instrument GCMS-S yielded a Percent Difference (%D) for chloromethane that were greater than the 25% quality control limit. The positive and nondetected results reported for this compound were qualified as estimated (J) and (UJ), respectively, in samples 46GW0701, 46GW0301, 46GW0801, 46GW1201(DL2), 46GW1001(DL2), and 46GW0301MS/MSD.

Surrogate percent recoveries (%Rs) for 1,2-dichloroethane-d4 were high in samples 44RB1214, 3221GW0301, 3221GW0101, 46GW0101, and 46GW0201. Only positive results are affected by this noncompliance. The positive results for compounds reported in these samples were qualified as estimated (J).

The Matrix Spike/Matrix Spike Duplicate (MS/MSD) analysis of sample 46GW0301 yielded high %Rs for 1,1,1-trichloroethane, bromodichloromethane, tetrachloroethane, and styrene. Additionally the Relative Percent Difference (RPD) for bromomethane was high. The positive result reported for bromodichloromethane in the unspiked sample was qualified as estimated (J). No action was necessary for the remaining compounds since only nondetected results were reported for these compounds.

The Laboratory Control Sample (LCS) associated with batch WG24245 had a Percent Recovery (%R) for 2-butanone that was greater than the upper quality control limit. No action was taken based on this noncompliances because results for 2-butanone in samples 46GW0101 and 46GW0201 were nondetected.

The LCS associated with batch WG24249 had %Rs for 1,2-dichloroethane and bromodichloromethane that were greater than the respective upper quality control limits. No actions were taken based on these noncompliances because all results for the aforementioned compounds were nondetected in the associated samples 46GW1401, 46GW1401D, and 46GW1501.

The LCS associated with batch WG24290 had %Rs for bromodichloromethane and styrene that were greater than the respective upper quality control limits. No actions were taken based on these noncompliances because all results for the aforementioned compounds were nondetected in the associated sample 46GW1601.

Samples 46GW1001(DL2), 46GW1201(DL2), and 46GW1601(DL2) were analyzed at a 2-fold dilution due to sample history, no undiluted analyses were performed. Hence these samples has slightly elevated reporting limits.

Semivolatiles

The initial calibration run on 1/10/06 had Percent Relative Standard Deviation (%RSD) that was in excess of the 30% quality control limit for hexachlorocyclopentadiene on instrument GCMS-K. The nondetected results reported for this compound in all samples in this SDG were qualified as estimated (UJ).

The continuing calibration run on 1/12/06 at 13:17 and 1/14/06 at 10:17 on instrument GCMS-K yielded %Ds for hexachlorocyclopentadiene, di-n-octylphthalate, and bis(2-chloroethyl)ether that were greater than the 25% quality control limit. Only quality control samples were run under these calibrations and quality control samples are not qualified for validation noncompliances.

All continuing calibration %Ds for hexachlorocyclopentadiene were greater than the 25% quality control limit. Only nondetects were reported for this compound in all samples in this SDG and these nondetects were qualified as estimated (UJ).

Additionally the continuing calibration run on 1/16/06 at 09:20 on instrument GCMS-K yielded a %D for di-n-octylphthalate that was greater than the 25% quality control limit. Only nondetects were reported for this compound in the affected samples 46GW1201, 46GW0901, 46GW1001, 46RB1217, 46GW1301, 46GW1401, 46GW1601, and 46GW0101 and these nondetects were qualified as estimated (UJ).

The MS/MSD analysis of sample 46GW0301 yielded low %Rs for 2,4-dimethylphenol, hexachlorocyclopentadiene, and 3,3'-dichlorobenzidine. The nondetected results reported for these compounds in the unspiked sample were qualified as estimated (UJ).

The LCS/LCSD associated with batch WG23949 had low %Rs for 3,3'-dichlorobenzidine. No actions were taken as a result of this noncompliance. This LCS was associated with samples 3221GW0201, 44RB1214, and 3221GW0301.

The LCS/LCSD associated with batch WG24038 had low %Rs for 2-nitroaniline, 2,4-dinitrophenol, and 3,3'-dichlorobenzidine. No actions were taken as a result of these noncompliances. This LCS/LCSD was associated with sample 3221GW0101.

PAHs

Naphthalene was detected in the rinsate blank. However environmental samples were not qualified based on rinsate blank contamination.

The continuing calibration run on instrument GCMS-U on 1/06/06 at 15:36 had a %D for benzo(b)fluoranthene that was in excess of the 25% quality control limit. However, the affected samples were all quality control samples (WG23950-Blank and WG23950-LCS) which are not qualified for noncompliances.

The continuing calibration run on instrument GCMS-U on 1/07/06 at 09:16 had %Ds for indeno(1,2,3-cd)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene that were in excess of the 25% quality control limit. However, the affected samples were all quality control samples (WG24039-Blank and WG24039-LCS) which are not qualified for noncompliances.

The continuing calibration run on instrument GCMS-U on 1/08/06 at 14:31 had %Ds for indeno(1,2,3-cd)pyrene, dibenzo(a,h)anthracene, benzo(a)anthracene, and benzo(bi)fluoranthene that were in excess of the 25% quality control limit. However, the affected samples were all quality control samples (WG24116-Blank, WG24116-LCS, 46GW0301MS) which are not qualified for noncompliances.

The continuing calibration run on 1/09/06 at 09:53 on instrument GCMS-U yielded %Ds for benzo(a)anthracene, benzo(b)fluoranthene, indeno(1,2,3-cd)pyrene, dibenz(a,h)anthracene, and benzo(g,h,i)perylene that were greater than the 25% quality control limit. Samples 3221GW0201, 44RB1214, 3221GW0301, 46GW1101, 46GW1201, 46GW1001, 46RB1217, and 46GW0901 are affected by these noncompliances. Only nondetected results were reported for these compounds in these samples and these were qualified as estimated (UJ).

The continuing calibration run on 1/10/06 at 13:09 on instrument GCMS-U yielded %Ds for benzo(a)anthracene, benzo(k)fluoranthene, and indeno(1,2,3-cd)pyrene that were greater than the 25% quality control limit. Samples 46GW1301, 46GW1401, 46GW1401D, 46GW1501, 46GW0101, 46GW0201, 46GW0801, 46GW0701, and 46GW0301 are affected by these noncompliances. Only nondetected results were reported for these compounds in these samples and these were qualified as estimated (UJ).

The MS/MSD analysis of sample 46GW0301 yielded low %Rs for benzo(b)fluoranthene and benzo(g,h,i)perylene. The nondetected results reported for these compounds in the unspiked sample were qualified as estimated (UJ). Additionally, the %Rs for dibenz(a,h)anthracene and indeno(1,2,3-cd)pyrene were less than 10%. Only nondetected results were reported for these compounds in these samples and these were rejected, qualified (UR).

Pesticide

The continuing calibration %Ds for gamma-BHC, heptachlor, and beta-BHC run on instrument gc08 column RTX-CLP1 on 1/10/06 at 11:15 were greater than 15%. No actions were necessary because no environmental samples were run under this calibration.

The continuing calibration %Ds for gamma-BHC, heptachlor, beta-BHC, aldrin, heptachlor epoxide, endosulfan I dieldrin, endrin, endosulfan II, endrin aldehyde, endosulfan sulfate, alpha-chlordane, gamma-chlordane, endrin ketone run on instrument gc08 column RTX-CLP1 on 1/10/06 at 21:50 were greater than 15%. No actions were necessary because no environmental samples were run under this calibration.

The continuing calibration %D for alpha-BHC run on instrument gc08 column RTX-CLPI on 1/11/06 at 20:25 was greater than 15%. No actions were necessary as the %D for this compound on column RTX-CLPII was compliant. Alpha-BHC was not detected in the affected samples 3221GW0201, 3221GW0301, 3221GW0101, 44RB1214, 46RB1217, 46GW1101, 46GW1201, 46GW0901, 46GW1001, and 46GW1301.

The continuing calibration %Ds for 4,4'-DDT, endrin aldehyde, and endrin ketone run on instrument gc08 column RTX-CLPI on 1/12/06 at 8:22 was greater than 15%. The %Ds for heptachlor epoxide and endrin ketone were greater than 15% on Column RTX-CLP II. No actions were taken for 4,4-DDT, endrin aldehyde, and heptachlor epoxide since they were noncompliant on only one column. The nondetected results reported for endrin ketone were qualified as (UJ) in the affected samples 46GW1401, 46GW1401D, 46GW1501, 46GW0101, 46GW0201, 46GW0801, 46GW0701, and 46GW0301.

The continuing calibration %Ds for endrin aldehyde, endosulfan sulfate, and endrin ketone run on instrument gc08 column RTX-CLPI on 1/12/06 at 21:38 was greater than 15%. The %Ds for endosulfan I, endrin aldehyde, and endrin ketone were greater than 15% on Column RTX-CLP II. No actions were taken for endosulfan sulfate and endosulfan I since they were noncompliant on only one column. The nondetected results reported for endrin ketone and endrin aldehyde were qualified as (UJ) in the affected samples 46GW1401, 46GW1401D, 46GW1501, 46GW0101, 46GW0201, 46GW0801, 46GW0701, and 46GW0301.

Continuing calibrations run on 1/18/06 at 19:45 on column RTX-CLP I, 1/19/06 at 13:37 on column RTX-CLP I, and 1/20/06 1:00 on columns RTX-CLPI and CLPII had %Ds for various compounds in excess of the 15% quality control limit. However no actions were necessary as only reanalyses were run under these calibrations and none of the reanalyses were used in the validation of this SDG.

The surrogate recoveries for decachlorobiphenyl (DCB) on column 1 and 2 were low in samples 3221GW0201, 46GW1001, 46GW1401, 46GW1401D, 46GW0201, and 46GW0801. Only nondetects were reported for pesticide compounds in these samples and these nondetects were qualified as estimated (UJ). These samples were reextracted and reanalyzed but showed little to no improvement in surrogate recoveries. Additionally these samples were reextracted grossly outside the maximum allowable holding time. Therefore, the reanalyses were not used in validation of this SDG.

The surrogate DCB %Rs on column 1 and 2 were less than 10% in sample 46GW1201 and 46GW1601. The nondetected results reported for pesticide compounds in these samples were rejected, qualified (UR). These samples were reextracted and reanalyzed but showed little to no improvement in surrogate recoveries and additionally were reextracted grossly outside the maximum allowable holding time. Therefore the reanalyses were not used in validation of this SDG.

PCBs

The continuing calibration average %D for Aroclor-1016 run on instrument gc06 on 1/19/06 at 16:04 were greater than 15% on both columns. The samples run under this calibration were all reanalyses and none of these results were used in the validation of this SDG.

The continuing calibration average %Ds for Aroclor-1016 run on instrument gc06 on 11/23/05 at 19:08 were greater than 15% on column RTX-35. No actions were warranted as no environmental samples are affected by this noncompliance and only one column is affected.

The continuing calibration average %Ds for Aroclor-1016 run on instrument gc06 on 1/10/06 at 14:12 was greater than 15% on column RTX-35. No actions were warranted as only one column is affected.

The continuing calibration average %Ds for Aroclor-1016 and Aroclor-1260 run on instrument gc06 on 12/29/05 at 4:54 were greater than 15% on column RTX-35. No actions were warranted as only one column is affected.

The surrogate recoveries for DCB on both columns were low in samples WG23986-blank, WG23986-LCS, 3221GW0201, 3221GW0301, 3221GW0101, 46GW1401, 46GW1401D, 46GW1501, 46GW0101, 46GW0201, 46GW0801, WG24714-blank, WG24714-LCS, 46GW1001, and 46GW0301. No action was necessary in the lab blanks and LCSs because they are quality control samples. The environmental samples were reextracted and reanalyzed and the reanalyses showed no improvements in surrogate recoveries and additionally the reanlayses were reextracted grossly outside the maximum allowable holding time. The nondetected PCB results reported in the aforementioned environmental samples were qualified as estimated (UJ).

The surrogate recoveries for DCB on both columns were less than 10% in samples 46GW1201(RA) and 46GW1601(RA). These samples were reextracted and reanalyzed and the reanalyses showed no improvements in surrogate recoveries and additionally the reanlayses were reextracted grossly outside the maximum allowable holding time. The nondetected PCB results reported in the aforementioned environmental samples were rejected, qualified (UR).

Total Petroleum Hydrocarbons

The following was detected in soil method blank:

Analyte	Maximum Detection	Action Level
TPH	240 ug/L	2400 mg/L

Sample aliquot and dilution factors were taken into consideration during the application of action limits. All positive results for TPH at concentrations less than the action level were qualified undetected (U) as a result of laboratory blank contamination.

The surrogate recoveries for triacontane-d62 and o-terphenyl were low in samples 46GW1201, 46GW1001, and 46GW1601. The samples were reextracted and reanalyzed as a result of these noncompliances and the reanalyses showed some improvement however the rextraction was performed outside the maximum allowable holding time. The original sample results were used in the validation of this SDG and the nondetected TPH results in these samples were qualified as estimated (UJ).

The surrogate %Rs for o-terphenyl were low in samples 3221GW0301, 46GW1401, 46GW1401D, 46GW0201, and 46GW0801. The nondetected TPH results in these samples were qualified as estimated (UJ).

The MS/MSD analysis of sample 46GW0301 yielded a high %R for TPH. No action was necessary in the unspiked sample because TPH was not detected.

EDB

The surrogate %Rs for tetrachloro-m-xylene (TCX) on column 1 were low in samples 3221GW0201, 44RB1214, 46GW1401, and 46GW1401D. The surrogate %Rs for TCX on columns 1 and 2 were low in samples 46GW1201, 46GW1001, 46GW0801, 46GW0801RE, and 46GW1601. The nondetected EDB results were qualified as estimated (UJ) in these samples.

The surrogate %Rs for TCX were high on both columns in sample 46GW1301. No actions were necessary as EDB was not detected in this sample.

Additional Comments:

Positive results less than the reporting limit (RL) were qualified as estimated "J", due to uncertainty near the detection limit.

EXECUTIVE SUMMARY

Laboratory Performance Issues: Qualifications were made on initial and continuing calibrations of acetone and 2-butanone which failed to comply with RRF or percent difference quality control criterion. Several VOC, SVOC, PAH, pesticide, and PCB compounds had noncompliant calibration %Ds. TPH was detected in the lab method blank.

Other Factors Affecting Data Quality: Surrogate non-compliances were noted in most fractions.

The data for these analyses were reviewed with reference to the EPA Functional Guidelines for Organic Data Validation (10/99). The text of this report has been formulated to address only those problem areas affecting data quality.

SDG NARRATIVE
KATAHDIN ANALYTICAL SERVICES
TETRA TECH NUS
CASE CTO 367 NAS PENSACOLA
SDG: CTO367-4

Sample Receipt

The following samples were received on December 15, 19 and 20, 2005 and were logged in under Katahdin Analytical Services work order numbers WV6688, WV6701 and WV6766 for a hardcopy due date of January 15, 2006.

KATAHDIN Sample No.	TTNUS Sample Identification
WV6688-1	3221GW0201
WV6688-2	44RB1214
WV6688-3	3221GW0301
WV6688-4	3221GW0101
WV6701-1	46GW1101
WV6701-2	46GW1201
WV6701-3	46GW0901
WV6701-4	46GW1001
WV6701-5	46RB1217
WV6701-6	46TB1217
WV6701-7	46GW1301
WV6701-8	46GW1401
WV6701-9	46GW1401D
WV6701-10	46GW1501
WV6701-11	46GW1601
WV6766-1	46GW0101
WV6766-2	46GW0201
WV6766-3	46GW0801
WV6766-4	46GW0701
WV6766-5	46GW0301

The samples were logged in for the analyses specified on the chain of custody form. All problems encountered and resolved during sample receipt have been documented on the applicable chain of custody forms.

We certify that the test results provided in this report meet all the requirements of the NELAC standards unless otherwise noted in this narrative or in the Report of Analysis.

Sample analyses have been performed by the methods as noted herein.

Should you have any questions or comments concerning this Report of Analysis, please do not hesitate to contact your Katahdin Analytical Services Project Manager, **Andrea J. Colby**. This narrative is an integral part of the Report of Analysis.

Organics Laboratory

The samples of SDG CTO367-4 were analyzed in accordance with "Test Methods for Evaluating Solid Wastes: Physical/Chemical Methods." SW-846. 2nd edition, 1982 (revised 1984), 3rd edition, 1986, and Updates I, II, IIA, and III 1996, Office of Solid Waste and Emergency Response, U.S. EPA, and/or Method for Determination of Petroleum Range Organics (Method #FL-PRO), Florida Department of Environmental Protection, November 1, 1995 and/or "Methods for the Determination of Organic Compounds in Drinking Water", U.S. EPA, Environmental Monitoring and Support Laboratory - Cincinnati (September 1995), for the specific methods listed below or on the Report of Analysis. Sample WV6688-4 was used for a matrix spike (MS) and matrix spike duplicate sample (MSD), as per client's request. Some manual integrations may have been performed due to split peaks and/or corrected baselines. All have been flagged with an "M" (software-generated) on the pertinent quantitation reports.

8260B Analysis

The reported percent recovery acceptance limits for the Laboratory Control Samples (LCSs) are statistically derived for the full list of spiked compounds. The recoveries of the spiked analytes in the LCS, Matrix Spike (MS) and Matrix Spike Duplicate (MSD) are compared to these acceptance limits. Katahdin standard operating procedure is not to take corrective action until greater than ten percent of the spiked analytes (with the exception of the common laboratory contaminants acetone and methylene chloride) in the LCS are outside of the QC limits. If the associated MS/MSD has greater than ten percent of the spiked analytes outside of the QC limits, no corrective action is taken, as long the LCS is acceptable.

The initial calibrations analyzed on the F instrument on 12/21/05 and on the M instrument on 12/22/05 had %RSD values for acetone that exceeded the method acceptance limit of 15%. Even though the %RSD is greater than 15%, acetone was calibrated with the average model since this calibration model is more accurate for this analyte at concentrations near the PQL than either the linear or quadratic calibration models.

Samples WV6688-2, 3, 4 and WV6766-1 and 2 had high recoveries for the surrogate 1,2-dichloroethane-d4, which were outside of the laboratory established acceptance limits. For those samples that had no target analytes detected above the PQL, since a high recovery would indicate a high bias the associated samples were not reanalyzed. For those samples that had target analytes detected above the PQL, since the recoveries of the second surrogate dibromofluoromethane, which is associated with the same internal standard as the surrogate 1,2-dichloroethane-d4, were acceptable, these samples were not reanalyzed. The laboratory is conducting a long-term corrective action plan to investigate the high recoveries of this surrogate.

Samples WV6701-2, 4, and 11 were analyzed at a dilution based on sample history. Consequently, the sample's PQLs were elevated accordingly.

8015M-FLPRO Analysis

Samples WV6688-3, WV6701-8 and 9 and WV6766-2 and -3 had low recoveries for the extraction surrogate o-terphenyl, which were outside of the method acceptance limits. Since the recoveries for

the second surrogate, n-triacontane-D_{62}, were within the acceptance limits, the samples were not reextracted.

Samples WV6701-2, 4 and 11 had low recoveries for the extraction surrogates o-terphenyl and n-triacontane-D_{62}, which were outside of the method acceptance limits. The samples were reextracted twenty days out of hold time and reanalyzed. The reextracted samples WV6701-2RE, 4RE and 11RE also had low recoveries for OTP. The results for both analyses are included in the report.

The target range PRO may have been detected above the MDL but below the MDL in some method blanks. Any PRO that was also detected in any of the associated samples was flagged with a "V" qualifier indicating that the analyte was detected in the method blank analyzed and/or extracted concurrently with the sample.

The matrix spike sample, WG24127-3, had a high PRO recovery, which was outside of the method acceptance limits. Since the recoveries were acceptable in the associated LCS and MSD, WG24127-2 and 4, respectively, the associated samples were not reextracted.

The CV standards (files CWA2120, CWA2132, CWA2145, CWA2158, CWA2162 and CWA2176) had low and/or high responses for one or more of the individual hydrocarbons, which resulted in %D's that were outside of the method acceptance limits of 25%. Since the method requirement applies to only the PRO range response, which was acceptable in all CV's, the associated samples were not reanalyzed.

504.1 Analysis

Samples WV6688-1, 2, WV6701-8 and 9 had low recoveries for the surrogate TCX on channel A, which were outside of the laboratory established acceptance limits. Since the recoveries for TCX were acceptable on channel B, the samples were not reextracted.

Sample WV6766-3 had low recoveries for the surrogate TCX on both channels, which were outside of the laboratory established acceptance limits. The sample was reextracted and analyzed with similar results indicating a matrix effect. The results from both extractions are included in the report.

Sample WV6701-7 had high recoveries for the surrogate TCX on both channels, which were outside of the laboratory established acceptance limits. Since a high recovery would indicate a high bias and the sample did not detect 1,2-dibromoethane above the PQL, the sample was not reextracted.

Samples WV6701-2, 4 and 11 had low recoveries for the surrogate TCX on both channels, which were outside of the laboratory established acceptance limits. Based on the appearance of the extracts after completing the extraction process, the low recoveries are likely due to a matrix effect and were therefore not reextracted.

Sample WV6701-11 was extracted within the 14 day holding time. The sample was deliberately not analyzed until all of the other samples were analyzed in order to avoid a possible instrument problem. This resulted in this sample being analyzed 4 days out of hold time. Also, the surrogate for sample WV6701-11 on channel A did not elute within the laboratories established retention time

window. Therefore, the peak was manually assigned and is flagged with the qualifier "*" on the form 8. The retention time on channel B was acceptable.

The opening calibration verification standard (CV) (file 3VL1212) had a low response for the surrogate TCX on channel A, which resulted in a %D that was outside of the method acceptance limits of 15%. Since the response was within the acceptance limits on the confirmation channel, the associated samples were not reanalyzed..

The closing CV (files 3VL1236 and 3VL2236) had low responses for the surrogate TCX on both channels, which resulted in %D's that were outside of the method acceptance limits of 30%.

The closing CV (file 3WA2043) had a high response for the surrogate TCX on channel B, which resulted in a %D that was outside of the method acceptance limits of 30%. Since the response was within the acceptance limits on the confirmation channel, the associated samples were not reanalyzed.

8270C SIM Analysis

The reported percent recovery acceptance limits for the Laboratory Control Samples (LCSs) are nominal limits for the full list of spiked compounds. The recoveries of the spiked analytes in the LCS, Matrix Spike (MS) and Matrix Spike Duplicate (MSD) are compared to these acceptance limits. Katahdin standard operating procedure is not to take corrective action until greater than ten percent of the spiked analytes (with the exception of the common laboratory phthalate ester contaminants) in the LCS are outside of the QC limits. If the associated MS/MSD have greater than ten percent of the spiked analytes outside of the QC limits, no corrective action is taken, as long the LCS is acceptable.

8270C Analysis

The reported percent recovery acceptance limits for the Laboratory Control Samples (LCSs) are statistically derived for the full list of spiked compounds. The recoveries of the spiked analytes in the LCS, Matrix Spike (MS) and Matrix Spike Duplicate (MSD) are compared to these acceptance limits. Katahdin standard operating procedure is not to take corrective action until greater than ten percent of the spiked analytes (with the exception of the common laboratory phthalate ester contaminants) in the LCS are outside of the QC limits. If the associated MS/MSD have greater than ten percent of the spiked analytes outside of the QC limits, no corrective action is taken, as long the LCS is acceptable.

The initial calibration analyzed on 01/10/06 had %RSD values for several analytes that exceeded the method acceptance limit of 15%. For these analytes, either a linear or quadratic model was used for quantitation instead of an average response factor. The target analyte hexachlorocyclopentadiene failed for both the linear and quadratic models in the initial calibration curve due to the correlation coefficient being less than the method acceptance criteria of 0.990. This compound was calibrated using the average model. Since this analyte was not detected above the MDL in the associated samples, the samples were not reanalyzed.

The calibration verification standards (CV) (file K1268 and K1329) had high responses for the calibration check compound (CCC) di-n-octylphthalate, which resulted in %D's that were outside

the method acceptance limit of 20%. Since a high response would indicate a high bias and this target analyte was not detected above the PQL, the associated samples were not reanalyzed.

8082 Analysis

The method blank, WG23986-1, the laboratory control sample, WG23986-2, samples WV6688-1, 3, 4, WV6701-8, 9, 10, 11, WV6766-1 through 3, and 5 had low recoveries for the extraction surrogate DCB on both channels, which were outside of the laboratory established acceptance limits. Per the client's request the samples were reextracted 23, 24 or 27 days out of hold time and analyzed. All of the recoveries for the surrogate DCB in the reextracted samples (with the exception of WV6766-1 and 5) were also low. Samples WV6701-2RE and 4RE also had low recoveries for the extraction surrogate TCX on both channels. The results from both extractions are included in the report.

The method blank, WG24714-1, laboratory control sample WG24714-2 and laboratory control sample duplicate WG24698-3 had low recoveries for the extraction surrogate DCB on both channels, which were outside of the laboratory established acceptance limits. Since these samples were associated with reextracted samples, no further corrective action was taken.

The closing calibration verification standards (CV's) (files 6VL3097 and 6VL4097) had low responses for DCB on both channels and low responses for Aroclor 1016, Aroclor 1260 and TCX on channel B, which resulted in %D's that were outside of the method acceptance limits of 15%. Since the responses were acceptable in the opening CV's, the associated samples were not reanalyzed.

The calibration verification standard (CV) (files 6WA2002) had a low response for DCB on channel B, which resulted in a %D that was outside of the method acceptance limits of 15%. Since the response was acceptable on the confirmation channel, the associated samples were not reanalyzed.

The Form 7 for the CV's (files 6VL3097, 6WA1027, 6WA2027, 6WA1084, 6WA2084, 6WA3072, 6WA4072, 6WA3110 and 6WA4110) are flagged for the surrogates TCX and/or DCB indicating that the %D is greater than the method acceptance limit of 15%. With the exception of DCB for file 6VL3097 and TCX for file 6WA3072, which were low, the %D's are actually within the method acceptance limits and should not be flagged, but due to software limitations the flagging could not be removed.

8081 Analysis

Samples WV6688-1, WV6701-2, 4, 8, 9 and 11 and WV6766-2 and 3 had low recoveries for the extraction surrogate DCB on both channels, which were outside of the laboratory established acceptance limits. Per the client's request the samples were reextracted 24, 25 or 28 days out of hold time and analyzed. All of the recoveries for the surrogate DCB in the reextracted samples were also low. Samples WV6701-2RE and 4RE also had low recoveries for the extraction surrogate TCX on both channels. The results from both extractions are included in the report.

The method blank, WG23986-1, the laboratory control sample, WG23986-2, samples WV6688-1, 3, 4, WV6701-8, 9, 10, 11, WV6766-1 through 3, and 5 had low recoveries for the extraction surrogate DCB on both channels, which were outside of the laboratory established acceptance limits. Per the client's request the samples were reextracted 23, 24 or 27 days out of hold time and analyzed. All of the recoveries for the surrogate DCB in the reextracted samples (with the exception of WV6766-1

and 5) were also low. Samples WV6701-2RE and 4RE also had low recoveries for the extraction surrogate TCX on both channels. The results from both extractions are included in the report.

The opening CV (file 8WA1136) had high responses for gamma-BHC, heptachlor, beta-BHC and TCX on the A channel, which resulted in %D's that were outside of the method acceptance limits of 15%. Since these analytes were within the method acceptance limits on the confirmation channel, the associated samples were not reanalyzed.

The closing CV (file 8WA1159) had high responses for most target analytes on the A channel, which resulted in %D's that were outside of the method acceptance limits of 15%. Since these analytes were within the method acceptance limits on the confirmation channel, the associated samples were not reanalyzed.

The opening CV (file 8WA1057) had a high response for TCX on channel A, which resulted in a %D that was outside of the method acceptance limits of 15%. Since all of the responses on the confirmation channel were within the acceptance limits, the associated samples were not reanalyzed.

The closing/opening CV (files 8WA1198 and 8WA2198) had high responses for 4,4'-DDD, endrin aldehyde and DCB on channel A, a low response for 4,4'-DDT on channel A, a low response for heptachlor epoxide on channel B, and high responses for endrin ketone on both channels. These responses resulted in %D's that were outside of the method acceptance limits of 15%. Since these analytes were within the method acceptance limits on the confirmation channel, with the exception of endrin ketone, and endrin ketone was not detected in any samples above the MDL, the associated samples were not reanalyzed.

The closing CV (files 8WA1222 and 8WA2222) had a high response endosulfan sulfate on channel A and high responses for endrin aldehyde and endrin ketone on both channels. These responses resulted in %D's that were outside of the method acceptance limits of 15%.

The opening CV (file 8WA3151) had a low response for alpha-BHC on the A channel, which resulted in a %D that was outside of the method acceptance limits of 15%. Since all responses were within the method acceptance limits on the confirmation channel, the associated samples were not reanalyzed.

The closing CV (files 8WA3172 and 8WA4172) had low responses gamma-BHC, heptachlor, delta-BHC and methoxychlor on channel A and low responses for alpha-BHC on both channels. These responses resulted in %D's that were outside of the method acceptance limits of 15%.

Some of the samples and the associated QC were put through a sulfur cleanup according to SW846 method 3660 using the copper powder technique. The cleanup had little or no effect on removing the sulfur. Consequently, some of the samples may have sulfur interference affecting the quantitation of target analytes. The results of the first analysis have been reported.

There were no other protocol deviations or observations noted by the organics laboratory staff.

QC Flag Legend

a - Target compound detected but, quantitated amount
Below Limit Of Quantitation(BLOQ).
R - Spike/Surrogate failed recovery limits.
M - Compound response manually integrated.

OVERVIEW

The sample set for CTO 367, NAS Pensacola, SDG 0605103 consists of ten (10) soild environmental samples. The samples were analyzed for select volatile organic compounds (VOC).

The samples were collected by TetraTech NUS on May 8, 2006 and analyzed by Empirical Laboratories. All analyses were conducted in accordance with SW-846 Method 8260B analysis and reporting protocols. The data contained in this SDG were validated with regard to the following parameters:

*	•	Data completeness
*	•	Holding times
*	•	GC/MS Tuning
	•	Initial and continuing calibration
	•	Blank results
	•	Surrogate spike recoveries
*	•	Internal standard recoveries
*	•	Blank Spike/Blank Spike Duplicate Results
*	•	Matrix Spike/Matrix Spike Duplicate Results
*	•	Detection Limits
*	•	Compound Quantitation
*	•	Compound Identification

The symbol (*) indicates that quality control criteria were met for this parameter. Problems affecting data quality are discussed below; documentation supporting these findings is presented in Appendix C. Qualified Analytical results are presented in Appendix A.

Volatiles

The following compounds were detected in the method blank at the maximum concentrations listed below:

Compound	Maximum Concentration	Blank Action Level
Methylene chloride[(1)]	7.7 ug/kg	77 ug/kg
Trichloroethene[(1)]	1.4 ug/kg	7 ug/kg

Methylene chloride[(2)]	380 ug/kg	3,800 ug/kg
Trichloroethene[(2)]	71 ug/kg	355 ug/kg

1 – Maximum concentration from low level method blanks.
2 – Maximum concentration from medium level blank.

An action level of 10X the maximum contaminant concentration was established to evaluate laboratory contamination for methylene chloride and 5X for trichloroethene. Dilution factors, percent solids, and sample aliquots were taken into consideration during the application of all action levels. The affected positive results were qualified (U) as a result of blank contamination for methyene chloride and trichloroethene.

A continuing calibration analyzed on instrument VOA1 on 05/09/06 @ 10:27 had a percent difference (%D) greater than the 25% quality control limit for bromomethane. The non-detected results for bromomethane in the affected samples were qualified as estimated, (UJ).

The surrogate dibromofluoromethane had percent recoveries less than the quality control limits for the following samples: 46SB3801, 46SB3901, and 46SB402. The non-detected results for the aforementioned samples have been qualified as estimated (J) and (UJ), respectively.

Additional Comments:

Samples 46SB3301 and 46SB3401 were analyzed as medium levels because of concentrations greater than the linear range of the instrument for several compounds.

The laboratory did not prepare and analyze a medium level method blank with the samples analyzed as medium level. This was done because the medium level sample vials sent from the field were not prepared by Empirical Laboratories so the methanol used was not of a known quality to the laboratory. However, the laboratory did take the low level soil method blank and recalculated the concentrations to be equivalent to a medium level soil blank preparation. This reconverted blank was then used to establish method blank contamination in the medium level soils.

EXECUTIVE SUMMARY

Laboratory Performance Issues: One compound exceeded calibration %D criterion, resulting in qualification of data. Two compounds were detected in the method blank resulting in qualification of the data.

Other Factors Affecting Data Quality: Surrogate non-compliances resulted in qualification of the data.

The data for these analyses were reviewed with reference to the EPA Functional Guidelines for Organic Data Validation (10/99), and the Department of Defense (DoD) document entitled "Quality Systems Manual (QSM) for Environmental Laboratories" (January 2006). The text of this report has been formulated to address only those problem areas affecting data quality.

"I attest that the data referenced herein were validated according to the agreed upon validation criteria as specified in the DoD QSM for Environmental Laboratories.

QUALIFIED ANALYTICAL RESULTS

Data Validation Qualifier Codes:

A = Lab Blank Contamination
B = Field Blank Contamination
C = Calibration Noncompliance (e.g. % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
C01 = GC/MS Tuning Noncompliance
D = MS/MSD Recovery Noncompliance
E = LCS/LCSD Recovery Noncompliance
F = Lab Duplicate Imprecision
G = Field Duplicate Imprecision
H = Holding Time Exceedance
I = ICP Serial Dilution Noncompliance
J = GFAA PDS - GFAA MSA's $r < 0.995$
K = ICP Interference - includes ICS % R Noncompliance
L = Instrument Calibration Range Exceedance
M = Sample Preservation Noncompliance
N = Internal Standard Noncompliance
N01 = Internal Standard Recovery Noncompliance Dioxins
N02 = Recovery Standard Noncompliance Dioxins
N03 = Clean-up Standard Noncompliance Dioxins
O = Poor Instrument Performance (e.g. base-line drifting)
P = Uncertainty near detection limit (< 2 x IDL for inorganics and <CRQL for organics)
Q = Other problems (can encompass a number of issues; e.g. chromatography,interferences, etc.)
R = Surrogates Recovery Noncompliance
S = Pesticide/PCB Resolution
T = % Breakdown Noncompliance for DDT and Endrin
U = % Difference between columns/detectors >25% for positive results determined via GC/HPLC
V = Non-linear calibrations; correlation coefficient $r < 0.995$
W = EMPC result
X = Signal to noise response drop
Y = Percent solids <30%
Z = Uncertainty at 2 sigma deviation is greater than sample activity

Volatiles

Method: The samples were extracted/analyzed by USEPA SW-846 Methods 5035/8260B (TerraCore field sampling followed by purge and trap then capillary column GC/MS) for soils upon receipt to the laboratory in satisfactory condition.
Comments: The volatile analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following note/exceptions:

- Sample analyses are based on screen results. Many samples are not reported without dilution. Soil samples are reported from the low-level vial and/or methanol extract, as necessary, depending on screen results and analyte concentrations.
- Methylene chloride and trichloroethene were detected in method blank V1PBLK0509 at concentrations below the quantitation limit. Reported concentrations in the associated samples within 5x the method blank concentration are flagged with a "V".
- Samples 46SB3801, 46SB3901 and 46SB402 had low recovery of the surrogate dibromofluoromethane. Reanalysis of samples 46SB3801 and 46SB3901 confirmed low recoveries. A check of the sample pH after analysis confirmed this is due to the high pH of the samples. Results for the reanalyses of samples 46SB3801 and 46SB3901 are reported with an "RE" appended to the sample ID.

I certify that, to the best of my knowledge and based upon my inquiry of those individuals immediately responsible for obtaining the information, the data package is in compliance with the terms and conditions of the contract, both technically and for completeness, with the exception of the conditions detailed in the case narrative, as verified by the following signature.

Marcia K. McGinnity
Senior Project Manager

ANALYTICAL REPORT TERMS AND QUALIFIERS (FLORIDA)

MDL: The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from analysis of a sample containing the analyte in a given matrix.

EQL/RL: The estimated quantitation limit (EQL)/reporting limit (RL) is defined as the estimated concentration above which quantitative results can be obtained with a specific degree of confidence. ELAB defines the EQL to be at or near the lowest standard of the calibration curve.

U: The presence of a "U" indicates that the analyte was analyzed for but was not detected or the concentration of the analyte quantitated below the MDL.

D: When a sample (or sample extract) is rerun diluted because one of the compound concentrations exceeded the highest concentration range for the standard curve, all of the values obtained in the dilution run will be flagged with a "D".

I: The presence of an "I" to the right of an analytical result indicates that the reported result is estimated. The data pass the identification criteria indicating that the compound is present, but the calculated result is less than the EQL/RL.

L: The concentration for any compound found which exceeds the highest concentration level on the standard curve for that compound will be flagged with a "L". Usually the sample will be rerun at a dilution to quantitate the flagged compound.

V: The presence of a "V" to the right of an analytical value indicates that this compound was also detected in the method blank and the data should be interpreted with caution. One should consider the possibility that the correct sample result might be less than the reported result and, perhaps, zero.

J1: The reported analyte concentration may have a high bias as the CCV exceeded the limit on the high side.

J2: The reported analyte concentration may have a low bias as the CCV exceeded the limit on the low side.

J3: The reported non-detect result may be due to a low bias as the CCV for the confirmation column exceeded the limit on the low side.

J4: The presence of a "J4" to the right of an analytical result indicates that the sample matrix interfered with the quantitation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.

OVERVIEW

The sample set for CTO 367, NAS Pensacola, SDG 0605104 consists of one (1) trip blank and twenty-three (23) soild environmental samples. Three field duplicates were included with this SDG: 46SB3501 / 46SB3501D, 46SB3701 / 46SB3701D, and 46SB3902 / 46SB3902D. The samples were analyzed for halogenated volatile organic compounds (VOC).

The samples were collected by TetraTech NUS on May 8, 2006 and analyzed by Empirical Laboratories. All analyses were conducted in accordance with SW-846 Method 8260B analysis and reporting protocols. The data contained in this SDG were validated with regard to the following parameters:

*	• Data completeness
*	• Holding times
*	• GC/MS Tuning
	• Initial and continuing calibration
	• Blank results
	• Surrogate spike recoveries
*	• Internal standard recoveries
*	• Blank Spike/Blank Spike Duplicate Results
	• Matrix Spike/Matrix Spike Duplicate Results
*	• Field Duplicate Results
*	• Detection Limits
*	• Compound Quantitation
*	• Compound Identification

The symbol (*) indicates that quality control criteria were met for this parameter. Problems affecting data quality are discussed below; documentation supporting these findings is presented in Appendix C. Qualified Analytical results are presented in Appendix A.

Volatiles

The following compounds were detected in the method blanks at the maximum concentrations listed below:

Compound	Maximum Concentration	Blank Action Level
Trichloroethene[1]	0.77 ug/kg	3.85 ug/kg
1,2-Dichlorobenzene[1]	0.31 ug/kg	1.55 ug/kg
1,3-Dichlorobenzene[1]	0.30 ug/kg	1.5 ug/kg
1,4-Dichlorobenzene[1]	0.26 ug/kg	1.3 ug/kg
1,2,4-Trichlorobenzene[1]	0.60 ug/kg	3.0 ug/kg
Bromomethane[2]	34 ug/kg	170 ug/kg
Chloromethane[2]	45 ug/kg	225 ug/kg
Trichloroethene[2]	29 ug/kg	145 ug/kg

1 – Maximum concentration from low level method blanks.
2 – Maximum concentration from medium level blank.

An action level of 5X the maximum contaminant concentration was established to evaluate laboratory contamination for all compounds. Dilution factors, percent solids, and sample aliquots were taken into consideration during the application of all action levels. The affected positive results were qualified (U) as a result of blank contamination for 1,2-dichlorobenzene, 1,4-dichlorobenzene, trichloroethene, 1,2,4-trichlorobenzene, and chloromethane. No qualification of the trip blank was taken based on method blank contamination.

A continuing calibration analyzed on instrument VOA4 on 05/19/06 @ 08:40 had a percent difference (%D) greater than the 25% quality control limit for bromomethane. The non-detected results for bromomethane in the affected samples were qualified as estimated, (UJ).

A continuing calibration analyzed on instrument VOA4 on 05/19/06 @ 20:34 had a percent difference (%D) greater than the 25% quality control limit for trichlorotrifluoroethane. The non-detected results for trichlorotrifluoroethane in the affected samples were qualified as estimated, (UJ).

A continuing calibration analyzed on instrument VOA4 on 05/20/06 @ 08:09 had a percent difference (%D) greater than the 25% quality control limit for bromomethane. The non-detected result for bromomethane in the sample 46SB3701 was qualified as estimated, (UJ).

A continuing calibration analyzed on instrument VOA5 on 05/11/06 @ 12:59 had a percent difference (%D) greater than the 25% quality control limit for dichlorodifluoromethane. The non-detected results for dichlorodifluoromethane in the affected samples were qualified as estimated, (UJ).

The surrogate dibromofluoromethane had percent recoveries less than the quality control limits for the following samples: 46SB3501D, 46SB3503, 46SB3601, 46SB3902, 46SB3902D, 46SB3903, 46SB4001, 46SB3701D, and 46SB3701. The positive and non-detected results for the aforementioned samples have been qualified as estimated (J) and (UJ), respectively.

The matrix spike / matrix spike duplicate (MS/MSD) performed on sample 46SB3402 had percent recoveries greater than the quality control limits for bromoform, carbon tetrachloride, chloroform, 1,3-dichlorobenzene, 1,4-dichlorobenzene, 1,1-dichloroethane, 1,2-dichloroethane, 1,1,1-trichloroethane, and trichlorotrifluoroethane. No action was taken on this basis because the MSD and LCS's had acceptable recoveries.

Additional Comments:

Samples 46SB3302, 46SB3303, 46SB3402, and 46SB3403 were analyzed as medium level soils and 46SB3303 at a 8X dilution because of concentrations greater than the linear range of the instrument for several compounds.

The medium level method blank associated with this SDG was prepared by the analyst using methanol from Empirical Laboratories. The methanol used in preparing the sample vials coming from the field is from

TerraCore. The brand of methanol used by Empirical Laboratories may or may not be the same brand of methanol used to prepare the sample vials by TerraCore. The medium level blank prepared by Empirical Laboratories was used to establish blank contamination in the environmental samples.

Positive results less than the reporting limit (RL) were qualified as estimated "J", due to uncertainty near the detection limit.

EXECUTIVE SUMMARY

Laboratory Performance Issues: Several compounds exceeded calibration %D criterion, resulting in qualification of data. Several compounds were detected in the method blanks resulting in qualification of the data.

Other Factors Affecting Data Quality: Surrogate non-compliances resulted in qualification of the data.

The data for these analyses were reviewed with reference to the EPA Functional Guidelines for Organic Data Validation (10/99), and the Department of Defense (DoD) document entitled "Quality Systems Manual (QSM) for Environmental Laboratories" (January 2006). The text of this report has been formulated to address only those problem areas affecting data quality.

"I attest that the data referenced herein were validated according to the agreed upon validation criteria as specified in the DoD QSM for Environmental Laboratories.

Appendix A – Qualified Analytical Results
Appendix B – Results as Reported by the Laboratory
Appendix C – Support Documentation

APPENDIX A

QUALIFIED ANALYTICAL RESULTS

Data Validation Qualifier Codes:

A = Lab Blank Contamination
B = Field Blank Contamination
C = Calibration Noncompliance (e.g. % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
C01 = GC/MS Tuning Noncompliance
D = MS/MSD Recovery Noncompliance
E = LCS/LCSD Recovery Noncompliance
F = Lab Duplicate Imprecision
G = Field Duplicate Imprecision
H = Holding Time Exceedance
I = ICP Serial Dilution Noncompliance
J = GFAA PDS - GFAA MSA's $r < 0.995$
K = ICP Interference - includes ICS % R Noncompliance
L = Instrument Calibration Range Exceedance
M = Sample Preservation Noncompliance
N = Internal Standard Noncompliance
N01 = Internal Standard Recovery Noncompliance Dioxins
N02 = Recovery Standard Noncompliance Dioxins
N03 = Clean-up Standard Noncompliance Dioxins
O = Poor Instrument Performance (e.g. base-line drifting)
P = Uncertainty near detection limit (< 2 x IDL for inorganics and <CRQL for organics)
Q = Other problems (can encompass a number of issues; e.g. chromatography,interferences, etc.)
R = Surrogates Recovery Noncompliance
S = Pesticide/PCB Resolution
T = % Breakdown Noncompliance for DDT and Endrin
U = % Difference between columns/detectors >25% for positive results determined via GC/HPLC
V = Non-linear calibrations; correlation coefficient $r < 0.995$
W = EMPC result
X = Signal to noise response drop
Y = Percent solids <30%
Z = Uncertainty at 2 sigma deviation is greater than sample activity

Volatiles

Method: The samples were extracted/analyzed by USEPA SW-846 Methods 5035/8260B or 5030B/8260B (TerraCore or VOA vial field sampling followed by purge and trap then capillary column GC/MS) for soils or trip blanks upon receipt to the laboratory in satisfactory condition.

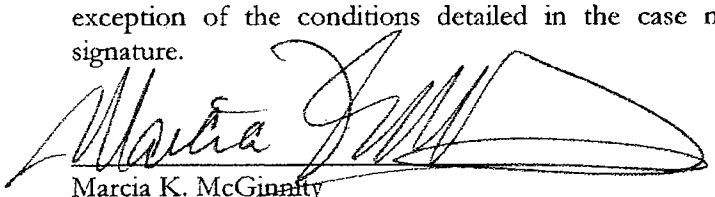
Comments: The volatile analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following note/exceptions:

- Sample analyses are based on screen results. Many samples are not reported without dilution. Soil samples are reported from the low-level vial and/or methanol extract, as necessary, depending on screen results and analyte concentrations. See table above for reported dilutions.

bromomethane, chloromethane, dichlorobenzenes, trichlorobenzene and/or trichloroethene at concentrations below the quantitation limit. Reported concentrations in the associated samples within 5x the method blank concentration are flagged with a "V".

- Several of the samples had low recovery of the surrogate dibromofluoromethane. Results from previously reported samples revealed this to be due to the high pH of the samples.
- In spike samples 46SB3402MS/MSD, 9 of 66 recoveries and 0 of 33 relative percent differences were outside the established limits. See form 3.

I certify that, to the best of my knowledge and based upon my inquiry of those individuals immediately responsible for obtaining the information, the data package is in compliance with the terms and conditions of the contract, both technically and for completeness, with the exception of the conditions detailed in the case narrative, as verified by the following signature.



Marcia K. McGinnity
Senior Project Manager

ANALYTICAL REPORT TERMS AND QUALIFIERS (FLORIDA)

MDL: The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from analysis of a sample containing the analyte in a given matrix.

EQL/RL: The estimated quantitation limit (EQL)/reporting limit (RL) is defined as the estimated concentration above which quantitative results can be obtained with a specific degree of confidence. ELAB defines the EQL to be at or near the lowest standard of the calibration curve.

U: The presence of a "U" indicates that the analyte was analyzed for but was not detected or the concentration of the analyte quantitated below the MDL.

D: When a sample (or sample extract) is rerun diluted because one of the compound concentrations exceeded the highest concentration range for the standard curve, all of the values obtained in the dilution run will be flagged with a "D".

I: The presence of an "I" to the right of an analytical result indicates that the reported result is estimated. The data pass the identification criteria indicating that the compound is present, but the calculated result is less than the EQL/RL.

L: The concentration for any compound found which exceeds the highest concentration level on the standard curve for that compound will be flagged with a "L". Usually the sample will be rerun at a dilution to quantitate the flagged compound.

V: The presence of a "V" to the right of an analytical value indicates that this compound was also detected in the method blank and the data should be interpreted with caution. One should consider the possibility that the correct sample result might be less than the reported result and, perhaps, zero.

J1: The reported analyte concentration may have a high bias as the CCV exceeded the limit on the high side.

J2: The reported analyte concentration may have a low bias as the CCV exceeded the limit on the low side.

J3: The reported non-detect result may be due to a low bias as the CCV for the confirmation column exceeded the limit on the low side.

J4: The presence of a "J4" to the right of an analytical result indicates that the sample matrix interfered with the quantitation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.

OVERVIEW

The sample set for CTO 367, NAS Pensacola, SDG 0605175 consists of fourteen (14) solid environmental samples and two aqueous environmental samples. The samples were analyzed for halogenated volatile organic compounds (VOC), polynuclear aromatic hydrocarbons (PAH), Florida PRO (FL-PRO), and bis(2-ethylhexyl)phthalate as indicated above.

The samples were collected by TetraTech NUS on May 10 and 11, 2006 and analyzed by Empirical Laboratories. All analyses were conducted in accordance with SW-846 Method 8260B, 8270C, and FL-PRO analysis and reporting protocols. The data contained in this SDG were validated with regard to the following parameters:

* • Data completeness
* • Holding times
* • GC/MS Tuning
• Initial and continuing calibration
• Blank results
• Surrogate spike recoveries
* • Internal standard recoveries
* • Blank Spike/Blank Spike Duplicate Results
* • Matrix Spike/Matrix Spike Duplicate Results
* • Detection Limits
* • Compound Quantitation

* • Compound Identification

The symbol (*) indicates that quality control criteria were met for this parameter. Problems affecting data quality are discussed below; documentation supporting these findings is presented in Appendix C. Qualified Analytical results are presented in Appendix A.

Volatiles

The following compounds were detected in the method blank at the maximum concentrations listed below:

Compound	Maximum Concentration	Blank Action Level
Methylene chloride[1]	3.0 ug/kg	30.0 ug/kg
Chloromethane[2]	74 ug/kg	370 ug/kg

1 – Maximum concentration from low level method blanks.
2 – Maximum concentration from medium level blank.

An action level of 10X the maximum contaminant concentration was established to evaluate laboratory contamination for methylene chloride and 5X for chloromethane. Dilution factors, percent solids, and sample aliquots were taken into consideration during the application of all action levels. The affected positive results were qualified (U) as a result of blank contamination for methyene chloride and chloromethane.

A continuing calibration analyzed on instrument VOA1 on 05/22/06 @ 11:48 had percent differences (%Ds) greater than the 25% quality control limit for bromoform and bromomethane. The non-detected results for bromofrom and bromomethane in sample 46SB4301 were qualified as estimated, (UJ).

The surrogate dibromofluoromethane had percent recoveries less than the quality control limits for sample 46SB4401. The positive and non-detected results for sample 46SB4401 have been qualified as estimated (J) and (UJ), respectively.

PAHs

The following compound was detected in the method blank at the maximum concentration listed below:

Compound	Maximum Concentration	Blank Action Level
Naphthalene	1.5 ug/kg	7.5 ug/kg

An action level of 5X the maximum contaminant concentration was established to evaluate laboratory contamination for naphthalene. Dilution factors, percent solids, and sample aliquots were taken into consideration during the application of all action levels. The affected positive results were qualified (U) as a result of blank contamination for naphthalene.

Bis(2-ethylhexyl)phthalate

No qualification of the data was necessary.

Florida-PRO

TPH was detected in the method blank at the maximum concentration listed below:

Compound	Maximum Concentration	Blank Action Level
TPH	5.8 mg/kg	29 mg/kg

An action level of 5X the maximum contaminant concentration was established to evaluate laboratory contamination for TPH. Dilution factors, percent solids, and sample aliquots were taken into consideration

during the application of all action levels. No qualification action was taken because all sample results were greater than the action level.

The surrogate nonatriacontane had percent recoveries less than the quality control limits for samples 45SB2901, 45SB3001, and the method blank. No action was taken on the method blank because QC samples are not qualified. The positive results for samples 45SB2901 and 45SB3001 have been qualified as estimated (J).

Additional Comments:

Sample 46SB4301 was analyzed as a medium level because of a concentration for trichloroethene greater than the linear range of the instrument.

Positive results less than the reporting limit (RL) were qualified as estimated "J", due to uncertainty near the detection limit.

EXECUTIVE SUMMARY

Laboratory Performance Issues: Two compounds exceeded calibration %D criterion for the VOA fraction, resulting in qualification of data. Several compounds were detected in the method blank for the VOA, PAH, and TPH fractions resulting in qualification of the data.

Other Factors Affecting Data Quality: Surrogate non-compliances for the VOA and TPH fractions resulted in qualification of the data.

The data for these analyses were reviewed with reference to the EPA Functional Guidelines for Organic Data Validation (10/99), and the Department of Defense (DoD) document entitled "Quality Systems Manual (QSM) for Environmental Laboratories" (January 2006). The text of this report has been formulated to address only those problem areas affecting data quality.

"I attest that the data referenced herein were validated according to the agreed upon validation criteria as specified in the DoD QSM for Environmental Laboratories.

Attachments:

Appendix A – Qualified Analytical Results
Appendix B – Results as Reported by the Laboratory
Appendix C – Support Documentation

APPENDIX A

QUALIFIED ANALYTICAL RESULTS

Data Validation Qualifier Codes:

A = Lab Blank Contamination
B = Field Blank Contamination
C = Calibration Noncompliance (e.g. % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
C01 = GC/MS Tuning Noncompliance
D = MS/MSD Recovery Noncompliance
E = LCS/LCSD Recovery Noncompliance
F = Lab Duplicate Imprecision
G = Field Duplicate Imprecision
H = Holding Time Exceedance
I = ICP Serial Dilution Noncompliance
J = GFAA PDS - GFAA MSA's $r < 0.995$ / ICP PDS Recovery Noncompliance
K = ICP Interference - includes ICS % R Noncompliance
L = Instrument Calibration Range Exceedance
M = Sample Preservation Noncompliance
N = Internal Standard Noncompliance
N01 = Internal Standard Recovery Noncompliance Dioxins
N02 = Recovery Standard Noncompliance Dioxins
N03 = Clean-up Standard Noncompliance Dioxins
O = Poor Instrument Performance (e.g. base-line drifting)
P = Uncertainty near detection limit (< 2 x IDL for inorganics and <CRQL for organics)
Q = Other problems (can encompass a number of issues; e.g. chromatography,interferences, etc.)
R = Surrogates Recovery Noncompliance
S = Pesticide/PCB Resolution
T = % Breakdown Noncompliance for DDT and Endrin
U = % Difference between columns/detectors >25% for positive results determined via GC/HPLC
V = Non-linear calibrations; correlation coefficient $r < 0.995$
W = EMPC result
X = Signal to noise response drop
Y = Percent solids <30%
Z = Uncertainty at 2 sigma deviation is greater than sample activity

Volatiles

Method: The samples were extracted/analyzed by USEPA SW-846 Methods 5035/8260B (TerraCore field sampling followed by purge and trap then capillary column GC/MS) for soils upon receipt to the laboratory in satisfactory condition.
Comments: The volatile analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following note/exceptions:

- Sample analyses are based on screen results. Soil samples are reported from the low-level vial and/or methanol extract, as necessary, depending on screen results and analyte concentrations.
- Chloromethane or methylene chloride were detected in the method blanks associated to these samples at concentrations below the quantitation limit. Reported concentrations in the associated samples are flagged with a "V".
- Sample 46SB4401 had low recovery of the surrogate dibromofluoromethane. A check of the sample pH after analysis confirmed this is due to the high pH of the samples.

Petroleum Range Organics

Method: The samples were analyzed by the Florida Petroleum Range Organics Method (FL-PRO, sonication extraction followed by capillary column GC/FID) for soils upon receipt to the laboratory in satisfactory condition.
Comments: The analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following exceptions:

- The surrogate nonatriacontane exceeded 25% difference on the low side in some of the continuing calibration verifications. Surrogate recoveries were evaluated and determined not to have been biased

into control by the exceedence.

- Method blank FS1BLK0518 has a reported concentrations of PRO below the quantitation limit. There are no reported concentrations within 5x the method blank concentration.
- Recoveries of the surrogate nonatriacontane are below the limit of 40% at 16%, 39% and 38%, respectively, in the analyses for FS1BLK0518, 45SB2901 and 45SB3001. All recoveries of the surrogate ortho-terphenyl were within limits. Past experience with the surrogate nonatriacontane indicate it is not a good indicator of PRO recovery.

Semivolatiles

Method: The samples were analyzed for bis(2-ethylhexyl)phthalate by USEPA SW-846 Methods 3510C/8270C (separatory funnel extraction followed by capillary column GC/MS) for waters upon receipt to the laboratory in satisfactory condition.
Comments: The analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications.

Semivolatile PAH Samples

Method: The samples were extracted/analyzed for polynuclear aromatic hydrocarbons by USEPA SW-846 Methods 3541/8270C (automated soxhlet extraction followed by capillary column GC/MS) for soils upon receipt to the laboratory in satisfactory condition.
Comments: The analyses for these samples were satisfactorily completed within sample holding times and met the corresponding specifications with the following exceptions:

- Note: These samples were analyzed for full-scan, low-concentration PAHs by employing a combination of sensitivity enhancing techniques in the extraction and analysis processes.
- Method blank SBLK0523BS1has a reported concentrations of naphthalene. Reported concentrations in the associated samples are flagged with a "V".

I certify that, to the best of my knowledge and based upon my inquiry of those individuals immediately responsible for obtaining the information, the data package is in compliance with the terms and conditions of the contract, both technically and for completeness, with the exception of the conditions detailed in the case narrative, as verified by the following signature.

Marcia K. McGinnity
Senior Project Manager

ANALYTICAL REPORT TERMS AND QUALIFIERS (FLORIDA)

MDL: The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The MDL is determined from analysis of a sample containing the analyte in a given matrix.

EQL/RL: The estimated quantitation limit (EQL)/reporting limit (RL) is defined as the estimated concentration above which quantitative results can be obtained with a specific degree of confidence. ELAB defines the EQL to be at or near the lowest standard of the calibration curve.

U: The presence of a "U" indicates that the analyte was analyzed for but was not detected or the concentration of the analyte quantitated below the MDL.

D: When a sample (or sample extract) is rerun diluted because one of the compound concentrations exceeded the highest concentration range for the standard curve, all of the values obtained in the dilution run will be flagged with a "D".

I: The presence of an "I" to the right of an analytical result indicates that the reported result is estimated. The data pass the identification criteria indicating that the compound is present, but the calculated result is less than the EQL/RL.

L: The concentration for any compound found which exceeds the highest concentration level on the standard curve for that compound will be flagged with a "L". Usually the sample will be rerun at a dilution to quantitate the flagged compound.

V: The presence of a "V" to the right of an analytical value indicates that this compound was also detected in the method blank and the data should be interpreted with caution. One should consider the possibility that the correct sample result might be less than the reported result and, perhaps, zero.

J1: The reported analyte concentration may have a high bias as the CCV exceeded the limit on the high side.

J2: The reported analyte concentration may have a low bias as the CCV exceeded the limit on the low side.

J3: The reported non-detect result may be due to a low bias as the CCV for the confirmation column exceeded the limit on the low side.

J4: The presence of a "J4" to the right of an analytical result indicates that the sample matrix interfered with the quantitation of the analyte. In GC and HPLC, results are reported from the column with the lower concentration.

OVERVIEW

The sample set for CTO 367, NAS Pensacola, SDG CTO367-2 consists of one (1) rinse blank, one (1) trip blank, and thirteen (13) soil environmental samples. One (1) field duplicate was included with this SDG: PEN46SB3001 / PEN46SB3001D. The samples were analyzed for volatile organic compounds (VOC), 1,2-Dibromoethane, semivolatile organic compounds (SVOC), polynuclear aromatic hydrocarbons (PAH), pesticides (PEST), polychlorinated biphenyls (PCB), and total petroleum hydrocarbons (TPH). The soil samples were also extracted using synthetic precipitation leachate procedure (SPLP) for VOCs. The trip blank was analyzed for VOCs only.

The samples were collected by TetraTech NUS on December 2, 2005 and analyzed by Katahdin Analytical Services, Inc. All analyses were conducted in accordance with Naval Facilities Engineering Service Center (NFESC) Quality Assurance/Quality Control (QA/QC) criteria using SW-846 Methods 8260B, 8270C, 8270C SIM, 8081, 8082, FLORIDA / PRO, and EPA Method 504.1 analysis and reporting protocols. The data contained in this SDG were validated with regard to the following parameters:

* • Data completeness
* • Holding times
* • GC/MS Tuning
• Initial and continuing calibration
• Blank results
• Surrogate spike recoveries
• Internal standard recoveries
• Blank Spike/Blank Spike Duplicate Results
• Matrix Spike/Matrix Spike Duplicate Results
• Field Duplicate Results
* • Detection Limits
* • Compound Quantitation
* • Compound Identification

The symbol (*) indicates that quality control criteria were met for this parameter. Problems affecting data quality are discussed below; documentation supporting these findings is presented in Appendix C. Qualified Analytical results are presented in Appendix A. Results as reported by the laboratory are presented in Appendix B.

Volatiles

The initial and continuing calibration analyzed on instrument GCMS-F had relative response factors (RRFs) less than the 0.05 quality control criteria for acetone and 2-butanone. The non-detected acetone and 2-butanone results for sample PEN46TB1202 have been rejected (UR).

Continuing calibration analyzed on instrument GCMS-F on 12/09/05 @ 11:43 had percent differences (%Ds) that exceeded the 25% quality control limit for 1,1,1-trichloroethane, carbon tetrachloride, 1,2-dichloroethane, and bromodichloromethane. The non-detected results for the aforementioned compounds in sample PEN46TB1202 were qualified as estimated, (UJ).

The initial and continuing calibration analyzed on instrument GCMS-M had relative response factors (RRFs) less than the 0.05 quality control criteria for acetone and 2-butanone. The positive and non-detected acetone and 2-butanone results for sample PEN46RB1202 have been qualified as estimated (J) and rejected (UR), respectively.

The initial calibration analyzed on instrument GCMS-S on 12/15/05 had relative response factors (RRFs) less than the 0.05 quality control criteria for acetone and 2-butanone. The positive and non-detected acetone and 2-butanone results for the affected samples have been qualified as estimated (J) and rejected (UR), respectively.

All continuing calibrations analyzed on instrument GCMS-S had relative response factors (RRFs) less than the 0.05 quality control criteria for acetone. The positive and non-detected acetone results for the affected samples have been qualified as estimated (J) and rejected (UR), respectively.

Continuing calibration analyzed on instrument GCMS-S on 12/19/05 @ 08:45 had percent differences (%Ds) that exceeded the 25% quality control limit for 2-butanone, 4-methyl-2-pentanone, and 2-hexanone. The non-detected results for the aforementioned compounds in the affected samples were qualified as estimated, (UJ).

Continuing calibration analyzed on instrument GCMS-S on 12/20/05 @ 09:27 had percent differences (%Ds) that exceeded the 25% quality control limit for chloroethane, 2-butanone, 4-methyl-2-pentanone, and 2-hexanone. The non-detected results for the aforementioned compounds in sample PEN45SB2503 were qualified as estimated, (UJ).

The soil initial calibration analyzed on instrument GCMS-Z on 12/06/05 had relative response factors (RRFs) less than the 0.05 quality control criteria for acetone and 2-butanone. The positive and non-detected acetone and 2-butanone results for the affected samples have been qualified as estimated (J) and rejected (UR), respectively.

All soil continuing calibrations analyzed on instrument GCMS-Z had relative response factors (RRFs) less than the 0.05 quality control criteria for acetone and 2-butanone. The positive and non-detected acetone and 2-butanone results for the affected samples have been qualified as estimated (J) and rejected (UR), respectively.

Soil continuing calibration analyzed on instrument GCMS-Z on 12/09/05 @ 08:28 had percent differences (%Ds) that exceeded the 25% quality control limit for carbon tetrachloride and 1,2-dichloroethane. The non-detected results for the aforementioned compounds in sample PEN46SB2903 were qualified as estimated, (UJ). No action was taken on samples PEN46SB2901 and PEN46SB2902 because the non-detected results were rejected due to low surrogate recoveries.

Soil continuing calibration analyzed on instrument GCMS-Z on 12/12/05 @ 11:28 had percent differences (%Ds) that exceeded the 25% quality control limit for chloromethane and bromomethane. The non-detected results for the aforementioned compounds in samples PEN46SB3001 and PEN46SB3003 were qualified as estimated, (UJ). No action was taken on sample PEN46SB3101 because the non-detected results were rejected due to low surrogate recoveries.

Soil continuing calibration analyzed on instrument GCMS-Z on 12/13/05 @ 10:39 had percent differences (%Ds)

that exceeded the 25% quality control limit for chloromethane and carbon tetrachloride. The non-detected results for the aforementioned compounds in the affected samples were qualified as estimated, (UJ).

Soil continuing calibration analyzed on instrument GCMS-Z on 12/14/05 @ 11:11 had percent differences (%Ds) that exceeded the 25% quality control limit for chloromethane, carbon tetrachloride, and 1,2-dichloroethane. The non-detected results for the aforementioned compounds in the affected samples were qualified as estimated, (UJ).

The following compounds were detected in the method or TCLP blanks:

Compound	Maximum Concentration	Blank Action Level
Methylene chloride[1]	5 ug/kg	50 ug/kg
Acetone[2]	9 ug/L	90 ug/L
Methylene chloride[2]	6 ug/L	60 ug/L
Chloroform[2]	0.8 ug/L	4 ug/L
Total xylenes[2]	2 ug/L	10 ug/L

1 – Maximum concentration from soil method blanks.
2 – Maximum concentration from SPLP blanks.

An action level of 10X the maximum contaminant concentration was established to evaluate laboratory contamination for acetone and methylene chloride and 5X for the other compounds. Dilution factors, percent solids, and sample aliquots were taken into consideration during the application of all action levels. The affected positive results were qualified (U) as a result of blank contamination for acetone, methylene chloride, chloroform, and total xylenes. No qualification of the QC blanks was taken based on method blank contamination. The positive results in the SPLP samples greater than the action limit were qualified as estimated (J) because of suspected laboratory contamination.

The surrogate dibromofluoromethane had percent recoveries less than 10% for soil samples PEN46SB2901, PEN46SB2902, and PEN46SB3101. The samples were re-analyzed and the dibromofluoromethane recoveries were less than 10%. The original sample analysis was used for validation. The positive results for the aforementioned soil samples were qualified as estimated (J). The non-detected results for the aforementioned soil samples were rejected (UR).

The surrogate dibromofluoromethane had a percent recovery less than the quality control limit for soil sample PEN46SB3102. The sample was re-analyzed within holding time with acceptable surrogate recoveries. The re-analyzed sample was used for validation. No qualification of the data was necessary.

The surrogates dibromofluoromethane, toluene-d8, and p-bromofluorobenzene had percent recoveries less than the quality control limit for soil sample PEN45SB2501. The sample was re-analyzed within the holding time with similar results. The re-analyzed results were used for validation. The positive and non-detected results for soil sample PEN45SB2501 have been qualified as estimated (J) and (UJ), respectively.

The surrogates toluene-d8 and p-bromofluorobenzene had percent recoveries less than the quality control limit for soil sample PEN45SB2503. The sample was re-analyzed within the holding time with acceptable results. The re-analyzed results were used for validation. No qualification of the data was necessary.

The surrogate 1,2-dichloroethane-d4 had percent recoveries greater than the quality control limit for aqueous samples PEN46TB1202, PEN46SB3003, PEN46SB3102, PEN46SB3103, PEN45SB2501, and PEN45SB2502. The positive results for the aforementioned samples have been qualified as estimated (J). No action was taken on the non-detected results.

The field duplicate pair PEN46SB3001 and PEN46SB3001D exceeded the 50% RPD and/or the difference between results was >2X RL quality control criteria for ethylbenzene and total xylenes. The positive and non-detected results for these compounds were qualified as estimated (J) and (UJ), respectively, in the aforementioned samples.

The laboratory control sample (LCS) associated with batch WG23738 had recoveries outside of the quality control limits for 2-butanone, chlorobenzene, total xylenes, and styrene. None of the percent recoveries were

less than 10%. No action was taken based on these non-compliances because all results were non-detected for the aforementioned compounds.

The LCS associated with batch WG24016 had recoveries greater than the quality control limits for 1,1,1-trichloroethane, 2-butanone, 1,2-dichloroethane, bromodichloromethane, and styrene. No action was taken based on these non-compliances because all results were non-detected for the aforementioned compounds.

The LCS associated with batch WG23923 had recoveries outside of the quality control limits for carbon disulfide and 2-butanone. None of the percent recoveries were less than 10%. No action was taken based on these non-compliances.

The LCS associated with batch WG24050 had recoveries greater than the quality control limits for carbon disulfide, 2-butanone, 1,2-dichloroethane, bromodichloromethane, and 4-methyl-2-pentanone. No action was taken based on these non-compliances because all results were non-detected for the aforementioned compounds.

The LCS associated with batch WG23726 had recoveries greater than the quality control limits for carbon tetrachloride, 1,2-dichloroethane, bromodichloromethane, and bromform. No action was taken based on these non-compliances because all results were non-detected for the aforementioned compounds.

The LCS associated with batch WG23858 had recoveries outside of the quality control limits for chloromethane, vinyl chloride, chloroethane, and bromodichloromethane. None of the percent recoveries were less than 10%. No action was taken based on these non-compliances.

Sample PEN46SB2901 was analyzed as a medium level because of a concentration for trichloroethene greater than the linear range of the instrument.

Semivolatiles

The following table summarizes the noncompliant surrogate spike recoveries and internal standard performances:

Samples	Surrogate Recoveries	Internal Standard Performances	Validated	Qualifications
PEN46SB2901	X(2)		Y	J, UJ Acid fraction only
PEN46SB2901RE	X(2) +(1)	6(L)	N	
PEN46SB2902	X(2)		Y	No action, only 1 surrogate out / frac.
PEN46SB2902RE	X(1)		N	
PEN46SB3103	X(2)		Y	J, UJ Acid fraction only
PEN46SB3103RE	+(3)	5(L)6(L)	N	
PEN45SB2501	+(2)	6(L)	Y	UJ for internal standard only
PEN45SB2501RA	+(1)	5(L)6(L)	N	
PEN45SB2502	+(2)	6(L)	Y	UJ for internalstandard only
PEN45SB2502RA	+(1)	5(L)6(L)	N	

Surrogate Recoveries: + Recovery greater than upper limit
X Recovery less than lower limit

Number of noncompliant surrogate recoveries noted in ( ).

Internal Standards: 1 – Pentafluorobenzene
2 – 1,4-Difluorobenzene
3 – Chlorobenzene-d5
4 – 1,4-Dichlorobenzene-d4

(L) indicates a low performance.
(H) indicates a high performance.

The initial calibration analyzed on instrument GCMS-K on 12/06/05 had a percent relative standard deviation (%RSD) that exceeded the 30% quality control limit for hexachlorocyclopentadiene. No action was taken on this basis because only a preparation blank and LCSs were associated with this initial calibration and QC samples do not require qualification.

Continuing calibration analyzed on instrument GCMS-K on 12/22/05 @ 09:07 had %Ds that exceeded the 25% quality control limit for nitrobenzene, 2,4-dinitrophenol, and 4-nitrophenol. No action was taken on this basis because only a preparation blank and LCSs were associated with this continuing calibration and QC samples do not require qualification.

Continuing calibration analyzed on instrument GCMS-K on 12/30/05 @ 15:47 had %Ds that exceeded the 25% quality control limit for hexachlorocyclopentadiene, 2,4-dinitrophenol, and 4,6-dinitro-2-methylphenol. The non-detected results for the aforementioned compounds in samples PEN46RB1202, PEN46SB2901, PEN46SB2902, and PEN46SB2903 were qualified as estimated, (UJ).

The continuing calibration analyzed on instrument GCMS-K on 01/08/06 @ 13:12 had a %D that exceeded the 25% quality control limit for di-n-octylphthalate. The non-detected results for di-n-octylphthalate in samples PEN46SB3001D, PEN46SB3002, PEN46SB3003, PEN46SB3101, PEN46SB3102, and PEN46SB3103 were qualified as estimated, (UJ).

Continuing calibration analyzed on instrument GCMS-K on 01/09/06 @ 13:35 had %Ds that exceeded the 25% quality control limit for bis(2-ethylhexyl)phthalate and di-n-octylphthalate. The positive and non-detected results for bis(2-ethylhexyl)phthalate and di-n-octylphthalate in samples PEN45SB2501, PEN45SB2502, and PEN45SB2503 were qualified as estimated, (UJ).

The initial calibration analyzed on instrument GCMS-K on 01/10/06 had a percent relative standard deviation (%RSD) that exceeded the 30% quality control limit for hexachlorocyclopentadiene. No action was taken on this basis because only re-analysis, re-extractions, and QC samples were associated with this initial calibration and none of these samples were used for validation.

Continuing calibration analyzed on instrument GCMS-K on 01/11/06 @ 09:55 had %Ds that exceeded the 25% quality control limit for N-nitroso-di-n-propylamine, hexachlorocyclopentadiene, and di-n-octylphthalate. No action was taken on this basis because only re-analysis samples were associated with this continuing calibration and none of these samples were used for validation.

Continuing calibration analyzed on instrument GCMS-K on 01/12/06 @ 13:17 had %Ds that exceeded the 25% quality control limit for hexachlorocyclopentadiene and di-n-octylphthalate. No action was taken on this basis because only re-extracted and QC samples were associated with this continuing calibration and none of these samples were used for validation.

Samples PEN46SB2903, PEN46SB3001, PEN46SB3001D, PEN46SB3003, and PEN45SB2503 had one surrogate outside of the quality control limit per fraction. No action was taken on this basis because only one surrogate was out per fraction and the recovery was greater than 10%.

The LCS / LCSD associated with the aqueous batch WG23602 had recoveries outside of the quality control

limits for 2,4-dimethylphenol, 2-nitroaniline, 2,4-dinitrophenol, and 3,3'-dichlorobenzidine. None of the percent recoveries were less than 10%. No action was taken based on these non-compliances.

The LCS / LCSD associated with the soil batch WG23807 had recoveries outside of the quality control limits for 4-chloroaniline, 3-nitroaniline, and N-nitrosodiphenylamine. The LCSD for 4-chloroaniline had a recovery less than 10% but the LCS was greater than 10%. No action was taken based on non-compliances for 3-nitroaniline and N-nitrosodiphenylamine. The non-detected 4-chloroaniline results for all samples except PEN45SB2502 and PEN45SB2503 were rejected (UR).

The LCS / LCSD associated with the soil batch WG23940 had recoveries outside of the quality control limits for 4-chloroaniline, 3-nitroaniline, 4-nitroaniline, N-nitrosodiphenylamine, and 3,3'-dichlorobenzidine. The LCS / LCSD for 4-chloroaniline had recoveries less than 10%. The non-detected 4-chloroaniline results for samples PEN45SB2502 and PEN45SB2503 were rejected (UR).

The LCS / LCSD associated with the soil batch WG24538 had recoveries outside of the quality control limits for several compounds and recoveries less than 10% for 4-chloroaniline and 3,3'-dichlorobenzidine. No action was taken on this basis because the samples associated with this LCS were re-extracted samples and were not used for validation.

The LCS associated with the soil batch WG24565 had recoveries outside of the quality control limits for several compounds. No action was taken on this basis because the samples associated with this LCS was re-extracted and were not used for validation.

Pesticide

Continuing verification %Ds exceeded the 15% quality control limit for alpha-BHC, gamma-BHC, heptachlor, beta-BHC, delta-BHC, dieldrin, 4,4'-DDT, gamma chlordane, and methoxychlor on 12/31/05 at 01:20 on column RTX-CLPI. The compounds 4,4'-DDT and methoxychlor exceeded 15% D on the RTX-CLPII column. The non-detected results for 4,4'-DDT and methoxychlor were qualified as estimated (UJ), in samples PEN46SB2901, PEN46SB2902, and PEN46SB2903.

Continuing verification %Ds exceeded the 15% quality control limit for endrin, 4,4'-DDT, endrin aldehyde, endosulfan sulfate, and methoxychlor on 01/06/06 at 05:19 on column RTX-CLPI. The compounds 4,4'-DDT and methoxychlor exceeded 15% D on the RTX-CLPII column. The positive and non-detected results for 4,4'-DDT and methoxychlor were qualified as estimated (J) and (UJ), respectively, in samples PEN46SB3001, PEN46SB3001D, PEN46SB3002, PEN46SB3003, PEN46SB3102, PEN46SB3103, and PEN45SB2502.

Continuing verification %Ds exceeded the 15% quality control limit for gamma-BHC, heptachlor, beta-BHC, delta-BHC, heptachlor expoxide, endosulfan I, 4,4'-DDE, dieldrin, endrin, 4,4'-DDT, endrin aldehyde, alpha-chlordane, and gamma-chlordane on 01/09/06 at 10:43 on column RTX-CLPI. All compounds met %D quality control limits on the RTX-CLPII column. No action was taken on this basis because %Ds were met on at least one column.

Continuing verification %Ds exceeded the 15% quality control limit for 4,4'-DDT, endosulfan sulfate, and methoxychlor on 01/09/06 at 21:18 on column RTX-CLPI. The compound endosulfan sulfate exceeded 15% D on the RTX-CLPII column. The non-detected results for endosulfan sulfate were qualified as estimated (UJ), in samples PEN46SB3101 and PEN45SB2503.

The relative percent difference (RPD) between columns exceeded 25% for the following compounds. The positive results were reported as estimated, (J) for the compounds below:

Sample	Compound	%D
PEN45SB2501	alpha-chlordane	48.8%
	4,4'-DDE	38.7%
	4,4'-DDT	26.0%
PEN45SB2502	4,4'-DDT	31.0%
PEN45SB2503	4,4'-DDT	34.6%

The surrogate decachlorobiphenyl had percent recoveries less than the quality control limits for sample PEN46RB1202. The non-detected results for sample PEN46RB1202 have been qualified as estimated (UJ).

The surrogate tetrachloro-m-xylene had a low recovery in the method blank and LCS associated with batch WG23876. No action was taken on this basis.

The surrogate decachlorobiphenyl had a low recovery in the method blank associated with batch WG23714. No action was taken on this basis.

The LCS / LCSD associated with batch WG23876 had percent recoveries less than the quality control limits for endosulfan II. The percent recovery for endosulfan II was not less than 10%. No action was taken based on this non-compliance.

Sample PEN45SB2501 (2X) required a dilution because of a concentration greater than the linear calibration range of the instrument for 4,4'-DDT. This accounts for the elevated detection limits for the non-detects in this sample.

PCB

A continuing verification average %D exceeded the 15% quality control limit for Aroclor-1016 on instrument GC06 on 11/23/05 at 19:08 on column RTX-35. Aroclor-1016 met average %D quality control limit on the RTX-5 column. No action was taken on this basis because the average %D was met on at least one column.

Continuing verification average %Ds exceeded the 15% quality control limit for Aroclor-1016 and Aroclor-1260 on instrument GC06 on 12/29/05 at 04:54 on column RTX-35. Aroclor-1016 and Aroclor-1260 met average %D quality control limit on the RTX-5 column. No action was taken on this basis because the average %D was met on at least one column.

A continuing verification average %D exceeded the 15% quality control limit for Aroclor-1260 on instrument GC06 on 12/31/05 at 04:13 on column RTX-5. Aroclor-1260 met average %D quality control limit on the RTX-35 column. No action was taken on this basis because the average %D was met on at least one column.

The surrogate decachlorobiphenyl had percent recoveries less than the quality control limits for sample PEN46RB1202. The non-detected results for sample PEN46RB1202 have been qualified as estimated (UJ).

The surrogate decachlorobiphenyl had a percent recovery greater than the quality control limit for sample PEN45SB2501 on the RTX-35 column. No action was taken on this basis because the percent recovery was acceptable on the RTX-5 column.

PAH

Continuing calibration analyzed on instrument GCMS-U on 12/27/06 @ 12:43 had %Ds that exceeded the 25% quality control limit for benzo(a)anthracene and benzo(k)fluoranthene. No action was taken on this basis because only QC samples were associated with this continuing calibration and QC samples are not qualified.

Continuing calibration analyzed on instrument GCMS-U on 01/03/06 @ 10:33 had %Ds that exceeded the 25% quality control limit for indeno(1,2,3-cd)pyrene, dibenzo(a,h)anthracene, and benzo(g,h,i)perylene. The positive and non-detected results for the aforementioned compounds in samples PEN46SB2903, PEN46SB3001, PEN46SB3001D, PEN46SB3002, PEN46SB3101, PEN46SB3102, and PEN46SB3103 were qualified as estimated, (J) and (UJ), respectively.

The continuing calibration analyzed on instrument GCMS-U on 01/06/06 @ 15:36 had a %D that exceeded the 25% quality control limit for benzo(b)fluoranthene. No action was taken on this basis because benzo(b)fluoranthene was not reported from the associated sample.

The following samples required a dilution because of concentrations greater than the linear range of instrument: PEN45SB2501 (25X), PEN45SB2502 (10X), and PEN45SB2503 (10X).

Total Petroleum Hydrocarbons (FLORIDA/PRO)

Total petroleum hydrocarbons were detected in the soil method blank and the rinse blank. Results less than 5X the method blank contamination (12 mg/kg) have been qualified as non-detected in all soil samples. No action was taken on the rinse blank.

The surrogate o-terphenyl had percent recoveries greater than the quality control limit for samples PEN46SB2901, PEN46SB2902, and PEN46SB3001. No action was taken on this basis because the TPH results for these samples were previously qualified as non-detected because of blank contamination.

The surrogates n-triacontane and o-terphenyl had percent recoveries greater than the quality control limit for sample PEN46SB2903. No action was taken on this basis because the TPH result for this sample was previously qualified as non-detected because of blank contamination.

Sample PEN45SB2501 (2X) required a dilution because of a TPH concentration greater than the linear range of instrument.

1,2-Dibromoethane (EDB)

The rinse blank (PEN46RB1202) was the only sample analyzed for EDB by EPA Method 504.1.

A continuing verification %D exceeded the 25% quality control limit for EDB on instrument GC03 on 12/15/05 at 21:17 on column SPB 608. EDB met the 25 %D quality control limit on the RTX-CLPII column. No action was taken on this basis because the %D was met on at least one column.

The LCS / LCSD associated with batch WG23818 had percent recoveries greater than the quality control limits. No action was taken on this non-compliance.

Additional Comments:

Positive results less than the reporting limit (RL) were qualified as estimated "J", due to uncertainty near the detection limit.

The laboratory did not report methyl acetate and caprolactum on the Form 1s or EDD. The laboratory submitted results upon request. The laboratory did not report EDB and 1,2-dibromo-3-chloropropane on the EDD. The laboratory submitted results upon request.

EXECUTIVE SUMMARY

Laboratory Performance Issues: Several compounds in the VOA, SVOA, Pest/PCB, and PAH fraction exceeded calibration %D and/or %RSD criterion, resulting in qualification and/or rejection of data. Several compounds were detected in the VOA and TPH fraction method blanks. The VOA, SVOA, Pest, and EDB fractions had LCS non-compliances.

Other Factors Affecting Data Quality: The VOA, SVOA, Pest/PCB, and TPH fractions had surrogate non-compliances. The SVOA fraction had internal standard non-compliances. Field duplicate imprecision was noted in the VOA fraction.

The data for these analyses were reviewed with reference to the EPA Functional Guidelines for Organic Data Validation (10/99), and the NFESC guidelines IRCDQM (Sept., 1999). The text of this report has been formulated to address only those problem areas affecting data quality.

"I attest that the data referenced herein were validated according to the agreed upon validation criteria as specified in the NFESC guidelines and the Quality Assurance Project Plan (QAPP)."

Appendix A – Qualified Analytical Results
Appendix B – Results as Reported by the Laboratory
Appendix C – Support Documentation

APPENDIX A

QUALIFIED ANALYTICAL RESULTS

Data Validation Qualifier Codes:

A = Lab Blank Contamination
B = Field Blank Contamination
C = Calibration Noncompliance (e.g. % RSDs, %Ds, ICVs, CCVs, RRFs, etc.)
C01 = GC/MS Tuning Noncompliance
D = MS/MSD Recovery Noncompliance
E = LCS/LCSD Recovery Noncompliance
F = Lab Duplicate Imprecision
G = Field Duplicate Imprecision
H = Holding Time Exceedance
I = ICP Serial Dilution Noncompliance
J = GFAA PDS - GFAA MSA's $r < 0.995$
K = ICP Interference - includes ICS % R Noncompliance
L = Instrument Calibration Range Exceedance
M = Sample Preservation Noncompliance
N = Internal Standard Noncompliance
N01 = Internal Standard Recovery Noncompliance Dioxins
N02 = Recovery Standard Noncompliance Dioxins
N03 = Clean-up Standard Noncompliance Dioxins
O = Poor Instrument Performance (e.g. base-line drifting)
P = Uncertainty near detection limit (< 2 x IDL for inorganics and <CRQL for organics)
Q = Other problems (can encompass a number of issues; e.g. chromatography,interferences, etc.)
R = Surrogates Recovery Noncompliance
S = Pesticide/PCB Resolution
T = % Breakdown Noncompliance for DDT and Endrin
U = % Difference between columns/detectors >25% for positive results determined via GC/HPLC
V = Non-linear calibrations; correlation coefficient $r < 0.995$
W = EMPC result
X = Signal to noise response drop
Y = Percent solids <30%
Z = Uncertainty at 2 sigma deviation is greater than sample activity
